Years, you may tranſplant them into the Places where they are deſigned to remain: The beſt Time for this Work is the latter End of *March* or the Beginning of *April*, juſt before the Plants begin to ſhoot; but in removing them you ſhould dig round their Roots, and cut off all downright or ſtrong Roots which have ſhot out to a great Diſtance, that you may the better preſerve a Ball of Earth to each Plant, otherwiſe they are ſubject to miſcarry: And when you have placed them in their new Quarters, you ſhould lay ſome Mulch upon the Surface of the Ground, to prevent its drying; and give them ſome Water twice a Week in very dry Weather; but do not repeat it too often when the Seaſon is favourable, nor give it to them in too great Quantities, which will rot the new Fibres and prevent their Growth. You ſhould alſo ſupport the Plants with Stakes until they have taken faſt hold of the Earth, to prevent their being turned out of the Ground, or diſplaced by the Winds, which will deſtroy the Fibres that were newly put out, and greatly injure the Plants. Theſe Trees delight in a middling Soil, which is neither too wet and ſtiff, nor too dry; tho' the latter is to be preferred to the former, provided it be freſh.

The Sort with ſtriped Leaves is at preſent pretty rare, and ſomewhat tenderer than the others, as are moſt Sorts of variegated Plants leſs capable to endure the Cold, than thoſe of the ſame Kinds which are plain; the ſtriping of Plants always proceeding from their Weakneſs: This is preſerved in ſome Gardens as a Curioſity, but may be propagated in the ſame manner with the former.

Thoſe Sorts with ſmall Leaves are commonly two Years before they take Root when layed, therefore they ſhould not be diſturbed ſooner; for the raiſing them out of the Ground does greatly retard their rooting.

The ninth, tenth, eleventh and twelfth Sorts are hardy Shrubs, which will thrive in the open Air in *England*. Theſe may be propagated by laying down of their Branches, after the manner directed for the firſt eight, and may afterward be managed in the ſame way.

The thirteenth Sort is very common in ſeveral Gardens in *Holland*, but is at preſent pretty rare in *England*. This Sort will not live abroad thro' the *Winter* in this Climate, ſo is always preſerved in Pots or Tubs, and removed into the Green-houſe in *Winter*, where if it is treated after the manner directed for the *Alaternoides*, they will thrive very well. This Sort is alſo propagated by laying down the tender Branches in the Spring of the Year, which muſt be duly watered in dry Weather; and by the following *Spring* they will have taken Root; when they ſhould be ſeparated from the old Plant, and planted in Pots filled with freſh Earth, and placed in the Shade until they have taken new Root; after which Time they may be expoſed during the *Summer* Seaſon, with other pretty hardy exotic Plants, in a ſheltered Situation, where they remain till *Autumn*, when they muſt be removed into the Green-houſe. Theſe Plants are ever-green, ſo that they make a pretty Variety in the Green-houſe, during the *Winter* Seaſon.

The fourteenth Sort grows plentifully in ſeveral Parts of the *Spaniſh Weſt-Indies:* The Seeds of this Kind were ſent to *England* by Mr. *Robert Millar*, who gathered them near *Carthagena* in *America*. The fifteenth Sort was diſcovered by Father *Plumier* in *America*, and ſince by Mr. *Millar* in the Iſland of *Tabago*, from whence he ſent ſome Seeds, but they did not ſucceed in *England*.

Theſe two Sorts are tender Plants, which muſt be kept in a warm Stove in *Winter*, otherwiſe they will not live in this country. They may be propagated by Seeds, which ſhould be obtained as freſh as poſſible from the Countries of their Growth, and muſt be ſown in Pots of freſh light Earth, and plunged into a Hot-bed of Tanners-bark, where they ſhould remain until the Plants come up, which is many times a Year from the Time of ſowing; ſo whenever the Seeds remain ſo long in the Ground, the Pots muſt be frequently watered in *Summer*, and in *Winter* the Glaſſes of the Hot-beds ſhould be covered with Mats, when the Weather is cold, to prevent the Froſt from entering of the Bed, which would deſtroy the Seeds.

When the Plants are come up, they ſhould be each tranſplanted into a ſmall Pot filled with freſh Earth, and then plunged into the Hot-bed again, obſerving to ſhade them from the Sun in the Heat of the Day, until they have taken new Root; after which Time they muſt have free Air admitted to them every Day, in Proportion to the Warmth of the Seaſon, and ſhould be conſtantly watered three or four times a Week in warm Weather. In this Bed the Plants may remain till *Autumn*, when they ſhould be removed into the Stove, and plunged into the Bark-bed, where, during the *Winter* Seaſon they ſhould be kept pretty warm, and muſt be frequently watered. Theſe Plants may remain in the Bark-ſtove for two Years or leſs, according as they acquire Strength; for when they are pretty ſtrong, they may be treated leſs tenderly, expoſing them in the middle of the Summer to the open Air, in a ſheltered Situation; and in Winter they may be placed in a dry Stove, where they ſhould have a moderate Degree of Warmth, in which they will thrive very well. Theſe Plants retain their Verdure throughout the Year, for which they are chiefly eſteemed.

PHLOMIS; [Φλομὶς, ſo call'd, of Φλέγω to *burn*, becauſe in old Time the Peaſants us'd to burn theſe Plants to enlighten their Chambers: It is alſo call'd *Herba Venti*; becauſe growing in Mountains, the Leaves of it are torn by the Wind] The Sage-Tree, *or* Jeruſalem-Sage.

The *Characters* are;

It hath a labiated Flower conſiſting of one Leaf, whoſe Upper-lip (or Helmet) which is creſted, does wholly reſt upon the Under-lip (or Beard,) which is divided into three Parts, and extends a little beyond the Upper-lip; the Pointal riſes out of the Flower-cup, accompany'd with four Embryo's, which afterwards become ſo many oblong Seeds, ſhut up in a Huſk, or a pentagonal Tube, which was before the Flower-Cup.

The *Species* are;

1. PHLOMIS *fruticoſa, ſalviæ folio latiore & rotundiore. Tourn.* Broad-leav'd Sage-tree, *vulgo.*
2. PHLOMIS *fruticoſa, ſalviæ folio longiore & anguſtiore. Tourn.* Narrow-leav'd Sage-tree, *vulgo.*
3. PHLOMIS *fruticoſa humilis latifolia candidiſſima, floribus luteis. Act. Phil.* Low Shrubby Sage-tree, with broad hoary Leaves, and yellow Flowers.
4. PHLOMIS *Narbonenſis, hormini folio, flore purpuraſcente. Tourn.* Narbon Jeruſalem Sage, with a Clary Leaf, and purpliſh Flower.
5. PHLOMIS *Hiſpanica candidiſſima herbacea. Tourn.* Spaniſh Jeruſalem Sage, with very hoary Leaves.
6. PHLOMIS *lychnitis. Cluſ. Hiſt.* Narrow-leav'd Jeruſalem Sage.
7. PHLOMIS *Samia herbacea, lunariæ folio. T. Cor.* Herbaceous Samian Jeruſalem Sage, with a Moonwort Leaf.
8. PHLOMIS *Orientalis, foliis laciniatis. T. C.* Eaſtern *Jeruſalem* Sage, with jagged Leaves.
9. PHLOMIS *Orientalis lutea herbacea latifolia verticillata. Act. Phil.* Broad-leav'd herbaceous Jeruſalem Sage from the *Levant*, with yellow Flowers growing in Whorles.
10. PHLOMIS *fruticoſa, flore purpureo, foliis rotundioribus. Inſt. R. H.* Shrubby *Jeruſalem* Sage, with a purple Flower, and rounder Leaves.
11. PHLOMIS *fruticoſa Luſitanica, flore purpuraſcente, foliis acutioribus. Inſt. R. H.* Shrubby *Jeruſalem* Sage of *Portugal*, with a purpliſh Flower, and ſharp-pointed Leaves.
12. PHLOMIS *Hiſpanica fruticoſa candidiſſima, flore ferrugineo. Inſt. R. H.* The whiteſt *Spaniſh* Shrub *Jeruſalem* Sage, with an iron-coloured Flower.
13. PHLOMIS *Orientalis lutea anguſtifolia, cymis fulveſcentibus, D. Sherard. Act. Phil. N.* 376. Yellow Eaſtern *Jeruſalem* Sage, with a narrow Leaf, and yellow Tops.

The three firſt-mention'd Sorts grow to be Shrubs of a middling Size, and are proper to intermix with other Sorts of Plants which are of the ſame Growth in ſmall Wilderneſs Quarters, where, by the Diverſity of their hoary Leaves, their large Spikes of yellow Flowers, and their long Continuance in flower, they make an agreeable Variety.

Theſe Plants have been preſerv'd in Pots, and placed in the Green-houſe in Winter among other tender Exoticks: but they are hardy enough to endure the Cold of our ordinary Winters in the open Air, provided they are planted in a dry Soil, and have a warm Situation; and are rarely injured by Cold, unleſs in a very ſevere Froſt.

They are propagated by Cuttings in this Country; for their Seeds do ſeldom ripen well in *England*, except in very warm dry Seaſons. The beſt time to plant theſe Cuttings is in *May*, that they may have good Roots before Winter: They ſhould be planted in a Bed of freſh light Earth, and ſhaded from the Sun until they have taken Root; after which, they will require no farther Care, but only to keep them clear from Weeds until the following *Spring*, when they may be removed to the Places where they are deſign'd to be continu'd.

The beſt Seaſon for tranſplanting them is in *March*, before they begin to ſhoot, obſerving to preſerve a Ball of Earth to the Root of each Plant, as alſo to water 'em until they have taken Root: And in order to form them into a regular Shape, they ſhould be ſtak'd, and their Stems kept conſtantly faſten'd thereto, until they arrive at the Height you deſign 'em; then you may ſuffer their Branches to ſhoot out on every Side, to make a handſome Head; in order to which, you ſhould prune off ſuch Branches as grow irregular to either Side, which muſt always be perform'd in *Summer*: for if they are wounded in *Winter*, the Cold does often injure the Plants, by entering the Wounds.

The Soil in which they are placed ſhould not be dung'd, for that cauſes them to grow too faſt, whereby their Shoots are too replete with Moiſture, and ſo leſs capable to endure the Cold; whereas if they are planted upon a dry, barren, rocky Soil, they are ſeldom injured by Cold, which is the Caſe of moſt of the ſame Claſs of Plants with Lip-flowers.

The other Sorts are all of them propagated by parting of their Roots, which ſhould be done in the *Spring* of the Year, obſerving to preſerve a leading Bud to each Off-ſet: Theſe ſhould alſo be placed in a dry, rocky, or gravelly Soil, in which they will thrive much better than if planted in a richer Ground, and will endure the Cold of our ordinary Winters extremely well in the open Air.

Theſe are Plants of no great Beauty, but are preſerved in the Gardens of thoſe who are fond of Variety. A *Tea* made with the Leaves of theſe Plants, is accounted very good for ſore Throats.

The four laſt ſorts grow to the Height of five or ſix Feet, and become ſhrubby: they are all of them pretty hardy, ſo will bear the Cold of our ordinary Winters in the open Air, provided they are planted on a dry Soil, and in a warm Situation: but as they are ſometimes deſtroyed by ſevere Froſts, ſo it is proper to keep a Plant of each Sort in Pots, which may be removed into Shelter in the Winter, in order to preſerve the Kinds. Theſe may be placed with Bays, and other hardy Plants, which only require to be defended from very hard Froſts, but muſt have as much free Air as poſſible in mild Weather; and ſhould be treated as hath been directed for the Sorts before enumerated. Theſe may be propagated by Cuttings, as the common Sort.

PHYTOLACCA, [This Plant is ſo call'd, of Φυτον a *Plant*, and *Lacca* a *Colour*, becauſe a Red Colour like *Lacca* is made thereof] American Night-ſhade.

The *Characters* are;

The Flower conſiſts of ſeveral Leaves, which are placed in a circular Order, and expand in form of a Roſe; out of whoſe Centre riſes the Pointal, which afterwards becomes a ſoft Fruit, or almoſt globular Berry full of Seeds, placed orbicularly: To which ſhould be added, that the Flowers and Fruit are produced on a Bunch like Currants.

The *Species* are;

1. PHYTOLACCA *Americana, majori fructu. Tourn.* American Nightſhade, with large Fruit, *commonly call'd* Virginian Poke *or* Porke Phyſick.
2. PHYTOLACCA *Americana, minori fructu. Tourn.* American Nightſhade, with leſſer Fruit.
3. PHYTOLACCA *Mexicana, baccis ſeſſilibus. Hort. Elth.* Branching Nightſhade of *Mexico*, with flatter Berries growing cloſe to the Stalk.

The firſt of theſe Plants is very common in *Virginia*, *New-England*, and *Maryland*, where the Inhabitants take a ſpoonful or two of the Juice of the Root, as a familiar Purge: The Berries thereof are full of a purple Juice, which gives a fine Tincture to Paper, from whence it hath the Name; but it will not abide long.

It may be propagated by ſowing the Seeds in the *Spring* upon a Bed of light rich Earth, and when they come up, they ſhould be tranſplanted into a Bed of rich dry Earth about two Feet aſunder; for they grow to be very large, eſpecially if the Soil be good. When they have taken Root, they will require no farther Care but only to clear 'em from Weeds, and in the *Autumn* they will produce their Flowers and Fruit: but when the Froſt comes on, it will cut down the Tops of theſe Plants, which conſtantly decay in Winter; but their Roots will abide in the Ground, and come up again the ſucceeding *Spring*. There is no great Beauty in this Plant; but, for Variety, a few of them may be placed in the Borders of large Gardens, ſince they require but little Culture.

The Sort with leſſer Fruit is tenderer than the former, and requires to be placed in an artificial Heat in *Winter*, otherwiſe they will not endure the Cold of our *Winters* in *England*: This is alſo propagated from the Seeds, which ſhould be ſown upon a moderate Hot-bed in the *Spring*; and when the Plants come up, they ſhould be tranſplanted each into a ſeparate ſmall Pot fill'd with light freſh Earth, and plung'd into another moderate Hot-bed to bring them forward: but when they have acquired ſome Strength, they ſhould be inured to bear the open Air by Degrees, into which they may be removed in *July*, obſerving to ſhift them into larger Pots, as their Roots ſhall require, and place them where they may be ſhelter'd from ſtrong Winds.

In this Situation they may remain 'till the Beginning of *September*, when they ſhould be remov'd into the Stove, placing them where they may have a temperate Warmth; and during the *Winter* Seaſon you ſhould frequently refreſh them with Water, but they muſt not have it in too great Quantities.

Theſe Plants will grow to be three Feet high, and may be train'd up with regular Stems and Heads; they will continue three or four Years, if carefully preſerv'd, and continue to produce Bunches of ſmall ſcarlet Berries throughout the whole Year; which affords a pleaſing Variety, amongſt other Exoticks in Winter, when few other things are in Beauty: The berries thereof are full of a beautiful red Juice, which will ſtain Paper extremely fine, but will not continue.

The third ſort grows in divers parts of *America*: the late Dr. *Houſton* obſerved it in great Plenty about *La Vera Cruz*, where the Sailors uſed to gather the Leaves of the Plant, and boil it inſtead of Spinach, which they eat without any ill Effects, tho' by moſt People theſe Plants were thought to have a poiſonous Quality.

It may be propagated by Seeds, which ſhould be ſown in the Spring on a moderate Hot-bed; and when the Plants are come up, they ſhould be tranſplanted on another Hot-bed, about four Inches aſunder, where they may grow till the Plants are pretty ſtrong, when they ſhould be carefully tranſplanted into Pots and plunged into a moderate Hot-bed, obſerving to ſhade them in the middle of the Day, until they have taken new Root; after which Time they ſhould have a large Share of freſh Air in warm Weather, and muſt be plentifully watered: with this Management the Plants will flower in *July*, and their Seeds will ripen in *September*. The Plants will continue two or three Years, provided they are placed in a Stove, and kept in a moderate Degree of Warmth, otherwiſe they will periſh in *Autumn*. The Berries of this Sort, when bruiſed, have a fine purple Juice, with which the Inhabitants make a fine Colour, but it is very apt to fade. The Juice of theſe Berries, mixt with Water in ſuch Proportion as to make a ſtrong Tincture, will tinge ſome white Flowers, ſo as to make them beautifully ſtriped; but eſpecially the Tuberoſe, whoſe Flowers when fully blown, ſhould be cut off, and the Stem ſet into a Phial of this Tincture, which in one Night will be drawn up into the Flower, and appear in beautiful purple Stripes by the next Day.

PILOSELLA, *vide* Hieracium.

PIMPINELLA, [This Plant is called *Pimpinella* for *Bipinella*, becauſe its Leaves grow or adhere to the Stalks by Pairs, and are diſpos'd like Feathers; it is alſo called *Sanguiſorba*, becauſe it ſtanches Blood] Burnet.

The *Characters* are;

The Flower conſiſts of one Leaf, which expands in a circular Form, and is generally cut into four Segments, to the Centre, accompanied with many Chives, or a tufted Pointal; the Flower-cup afterwards becomes a Fruit, for the moſt part ſharp-pointed and quadrangular; having ſometimes but one Cell, and at other times two Cells, which are full of oblong Seeds.

The *Species* are;

1. PIMPINELLA *ſanguiſorba minor lævis. C. B. P.* Common or leſſer Burnet.
2. PIMPINELLA *ſanguiſorba major. C. B. P.* Great Burnet.
3. PIMPINELLA *major præalta auriculata Sabauda. Bocc. Muſ.* Great rigid tall Burnet, with auriculated Leaves.
4. PIMPINELLA *maxima Canadenſis. Corn.* Greateſt Canada Burnet.

There are ſome other Species of this Plant, which are preſerved in curious Botanick Gardens for Variety: But thoſe here mentioned are what I have obſerved in the *Engliſh* Gardens.

The common *Burnet* is found wild in great Plenty upon dry chalky Hills, in divers Parts of *England*: yet is often cultivated in Gardens for medicinal Uſes; though the Herb gather'd on its native Place of Growth, is much ſtronger, and fitter for ſuch Purpoſes.

The ſecond Sort is found growing in moiſt Meadows, and other wet Soils in divers Parts of *England*, and is rarely cultivated in Gardens.

The other two Sorts are Strangers to our Country, but are hardy enough to endure the Cold of our Climate in the open Air. Theſe may be propagated either by ſowing of the Seeds, or parting their Roots.

The beſt Time for parting their Roots, is in the *Autumn*, that they may take good Root before the Drought of the *Spring* hinders their Growth. They ſhould be planted in Beds of light dry Earth, about ten Inches or a Foot aſunder, for if they have not Room to ſpread, they will rot each other. In *May* they will ſhoot up to flower; but if you would preſerve the Roots, the Stems ſhould be conſtantly cut off, for if they are permitted to ſeed, they ſeldom remain long after.

They may alſo be propagated by ſowing their Seeds upon a Bed of light Earth in the *Spring*, and when the Plants are come up, they ſhould be tranſplanted out into a Bed of freſh Earth, at the Diſtance before-mention'd, obſerving to water and ſhade them until they have taken Root, after which they will require no farther Care, but to keep them clear from Weeds. The firſt Sort is what ſhould be uſed in Medicine, and the Leaves of that are alſo put into cool Tankards in the Heat of Summer, as a Cordial Herb.

To this *Article* muſt be added;

1. PIMPINELLA *major Hiſpanica, ſpicâ dilutè rubente. H. R. Par.* Greater *Spaniſh* Burnet, with a pale red Spike.
2. PIMPINELLA *major Hiſpanica altera, conglomerato flore. H. R. Par.* Another large *Spaniſh* Burnet, with a conglomerated Flower.
3. PIMPINELLA *Canadenſis, ſpicâ longâ rubente. H. R. Par.* *Canada* Burnet, with a long red Spike.
4. PIMPINELLA *agrimonoides odorata. H. R. Par.* Sweet-ſcented Burnet, with the Appearance of Agrimony.
5. PIMPINELLA *ſanguiſorba minor hirſuta. C. B. P.* Leſſer rough Burnet.
6. PIMPINELLA *ſanguiſorba inodora. C. B. P.* Unſavory Burnet.
7. PIMPINELLA *ſanguiſorba minor, ſemine majore & craſſiore. Bot. Monſp.* Smaller Burnet, with a larger and thicker Seed.
8. PIMPINELLA *ſpinoſa, ſeu ſempervirens. Mor. Umb.* Prickly ever-green Burnet.

The firſt, ſecond, third, fifth, ſixth and ſeventh Sorts, are hardy Plants, which continue ſeveral Years, and will live in the open Air. Theſe may be propagated after the ſame manner as the common Sort, either by parting of the Roots in Autumn, or by Seeds, as hath been directed in the former part of this Article.

The fourth Sort is a biennial Plant, which is only cultivated by Seeds. The Seeds of this Sort ſhould be ſown in *March*, on a Bed of light freſh Earth in an open Situation; and when the Plants are come up, they ſhould be carefully cleared from Weeds, and thinned where they are too cloſe; and as the Plants increaſe in Size, ſo they ſhould be reduced to leave them about a Foot apart, and many times the Plants will flower the ſame Year they were ſown; but they always flower the ſecond Year, and produce ripe Seeds, but ſeldom continue long after. The Leaves of this Plant, when rubbed, emit a grateful Odour.

The eighth Sort is an abiding Plant, which riſes to the Height of two Feet or more, and becomes ſhrubby. The ſlender Branches of this Plant are beſet with Thorns, at the Joints where the Leaves are produced; the Flowers are very ſmall, and of an herbaceous Colour, which are ſeldom ſucceeded by Seeds in this Country.

This is propagated by Cuttings, which ſhould be planted in the ſummer Months, on a Bed of freſh light Earth, and ſhould be ſhaded either with Mats or oiled Paper, until they have taken Root, which will be in about ſix Weeks, or two Months, if they are carefully watered. When the Cuttings are rooted, they ſhould be carefully taken up, and planted into ſeparate Pots, filled with light freſh Earth, and placed in a ſhady Situation, until they have taken new Root; after which Time they may be expoſed in a ſheltered Situation, till the middle or latter End of *October*, when they ſhould be placed under a Frame, to defend them from the hard Froſt in Winter; but they muſt have as much free Air as poſſible in mild Weather; and in the Spring they ſhould be placed abroad with Myrtles, and other hardy Plants, obſerving to water them duly in dry Weather. With this Management the Plants will thrive very well, and may be continued ſeveral Years.

PINASTER, *vide* Pinus Sylveſtris.

PINUS, The Pine-tree.

The *Characters* are;

It hath amentaceous Flowers, (or Catkins) which are produced at remote Diſtances from the Fruit on the ſame Tree; the Seeds are produced in ſquamous Cones; to which ſhould be added, that the Leaves are longer than thoſe of the Firr-tree, *and are produced by Pairs out of each Sheath.*

The *Species* are;

1. PINUS *ſativa. C. B. P.* The manured *Pine*.
2. PINUS *ſylveſtris. C. B. P.* The Pinaſter or wild *Pine*.
3. PINUS *ſylveſtris foliis brevibus glaucis, conis parvis albentibus. Raii Hiſt.* The Scotch *Pine*, *commonly call'd* the Scotch Firr.
4. PINUS *Americana, foliis prælongis, ſubinde ternis, conis plurimis confertim naſcentibus. Rand.* American *Pine*, with longer Leaves coming out by Threes, and many Cones growing in a Cluſter, *commonly called* The Cluſter Pine.
5. PINUS *Americana, ex uno folliculo, ſetis longis tenuibus triquetris, ad unum angulum, per totam longitudinem, minutiſſimis crenis aſperatis. Pluk. Amalth.* Lord *Weymouth*'s *Pine*; vulgo.

The Culture and Management of theſe Trees, being the ſame as for *Firrs*, is fully ſet down adjoining to that Article, for which the Reader is deſired to turn back to *Abies*.

To this *Article* muſt be added;

1. PINUS *ſylveſtris montana tertia. C. B. P.* The third wild mountain Pine, of *Caſpar Bauhin*.
2. PINUS *ſylveſtris montana altera. C. B. P.* Another wild mountain Pine.
3. PINUS *ſylveſtris maritima, conis firmiter ramis adhærentibus. J. B.* Wild maritime Pine, whoſe Cones adhere firmly to the Branches.
4. PINUS *maritima altera Matthioli. C. B. P.* Another maritime Pine of *Matthiolus*.
5. PINUS *maritima minor. C. B. P.* Leſſer maritime Pine.
6. PINUS *humilis, iulis vireſcentibus aut palleſcentibus. Inſt. R. H.* Dwarf Pine, with a green or pale Katkin.
7. PINUS *humilis, iulo purpuraſcente. Inſt. R. H.* Dwarf Pine, with a purpliſh Katkin.
8. PINUS *conis erectis. Inſt. R. H.* Pine whoſe Cones grow erect.
9. PINUS *Orientalis, foliis durioribus amaris, fructu parvo peracuto. Tourn. Cor.* Eaſtern Pine, with harder bitter Leaves, and a ſmall ſharp-pointed Cone.
10. PINUS *Hieroſolymitana, prælongis & tenuiſſimis viridibus ſetis. Pluk. Almag.* Eaſtern Pine, with long narrow green Leaves.
11. PINUS *Virginiana, prælongis foliis tenuioribus, cono echinato. Pluk. Almag.* *Virginian* Pine, with longer narrower Leaves, and a rough Cone.
12. PINUS *Virginiana tripilis ſ. ternis plerumque ex uno folliculo ſetis, ſtrobilis majoribus. Pluk. Almag.* *Virginian* Pine, having for the moſt part three Leaves, coming out of one Sheath, commonly called the Frankincenſe-tree.
13. PINUS *Virginiana, binis brevioribus & craſſioribus ſetis, minori cono, ſingulis ſquammarum capitibus aculeo donatis. Pluk. Alm.* *Virginian* Pine, with ſhorter thicker Leaves, and ſmaller Cones, with a Prickle on the Top of each Scale, commonly called the *Jerſey* Pine.
14. PINUS *Americana paluſtris patula, longiſſimis & viridibus ſetis.* Marſh ſpreading *American* Pine, with the longeſt green Leaves.

The eight firſt-mentioned Sorts grow wild in *Auſtria*, *Spain*, *Portugal*, and ſome other Parts of *Europe*. Theſe are all of them very hardy, and may be propagated by Seeds, in the ſame manner as hath been directed for the Firs, under the Article *Abies*.

The tenth Sort grows upon the Hills in the Neighbourhood of *Aleppo*, and in ſeveral other Places in the *Eaſt*. The Cones of this Kind are ſmall, and the Seeds are deſtitute of Wings. This Sort is very hardy; for I have ſown the Seeds in an open Bed of Earth, where the Plants have come up, and have made great Progreſs, without any farther Care but keeping them clear from Weeds. This Sort is very quick of Growth, and endures the Cold extremely well.

The ninth Sort was diſcovered by Doctor *Tournefort* in the *Levant*, from whence he ſent the Seeds to the Royal

Garden at *Paris*. This bears the Cold extremely well, and may be propagated by Seeds, as the common Sorts.

The eleventh, twelfth, thirteenth and fourteenth Sorts are Natives of *America*, from whence their Cones have been brought into *Europe*, and many of the Plants have been raiſed, which are in the Gardens of ſeveral curious Gentlemen. Theſe Plants are ſomewhat tender, when they firſt ariſe from Seeds; ſo they ſhould be particularly taken Care of, the firſt Summer, otherwiſe they will drop away in a ſhort Time. The Seeds of theſe Kinds ſhould be ſown in Pots or Tubs filled with very light Earth, and they ſhould have ſome light ſhifted Earth ſpread over them, about a quarter of an Inch thick. Theſe Pots or Tubs muſt be ſhaded with Mats or oiled Paper, to ſcreen the Plants from the Sun; and theſe Coverings ſhould be taken off every Night, unleſs the Weather is cold or ſtormy, when they ſhould be continued on. For if the Plants are expoſed to too much Wet, or ſtrong Winds, it will deſtroy them while they are very young; tho', when they have obtained ſtrength, they will reſiſt the ſeverity of Weather extremely well. The Plants ſhould be frequently refreſhed with Water, but it muſt not be given to them in large Quantities, for the Reaſon before aſſigned. Toward the middle of the Summer, the Plants ſhould be expoſed to the Sun by degrees, taking the Covers off in the Afternoon, and letting them remain off longer in the Morning, ſo that by the middle of *July*, they may be quite expoſed in the open Air, obſerving to water them duly in dry Weather. About the latter End of *October*, the Pots or Tubs muſt be placed under a common Frame, where they may be ſheltered from exceſſive Rains or Froſts in the Winter; but they muſt have as much free Air as poſſible in mild Weather. The following Spring theſe Plants ſhould be tranſplanted, when there muſt be a Bed of light freſh Earth prepared, in a well-ſheltered Situation; and in the Beginning of *April*, if the Seaſon proves warm, they may be removed; but if it ſhould prove cold, it is much better to defer it a little later in the Month. In taking of them up, great Care ſhould be had, that the Fibres of their Roots are not broken, as alſo to plant them immediately; for if the Air dries their Roots, they very rarely ſurvive it. The Diſtance theſe Plants ſhould be planted in the Bed, is about ten Inches or a Foot; and as ſoon as they are planted, they ſhould be gently watered three or four times over, ſo as to moiſten the Earth throughly, but not to bear down the Plants. Then the Bed ſhould be arched over with Hoops or Withies, and covered with Mats, or oiled Paper, to ſcreen the Plants from the Sun and drying Winds, until they have taken Root, after which Time they ſhould be inured to bear the open Air by degrees; but then it will be proper to lay ſome Mulch on the Surface of the Ground, to prevent the Sun and Air from penetrating of the Ground, ſo as to dry the Fibres of the Plants; and during this Seaſon, the Plants muſt be watered in dry Weather; for as they have but ſmall rooting in the Ground while they are young, ſo a little Drought will greatly injure, if not abſolutely deſtroy them. The following Winter, if the Froſt ſhould prove extremely hard, it will be of great Service to the Plants, to ſcreen them with oak Branches, which retaining of their Leaves, will greatly protect the Plants from the Severity of the Froſt, and they will not be ſo cloſe as to exclude the Air wholly from them. But when the Froſt is over, the Branches ſhould be taken away by degrees, ſo as not to expoſe the Plants at once to the open Air; for an Indiſcretion of this Kind may deſtroy more Plants than the Froſt would have done, if they had been expoſed thereto.

In this Bed the Plants may remain two Years, when it will be proper to tranſplant them where they are to remain for good; for theſe Plants do not bear tranſplanting when they are large. When this is performed, it ſhould be in *April*, juſt before the Plants begin to ſhoot, and, if poſſible, in a rainy or cloudy Seaſon. The Plants ſhould be taken up with good Balls of Earth to their Roots, and the Holes ſhould be opened, and thoroughly moiſtened before, ſo that the Plants may be immediately planted after they are taken up, that their Roots may not ſuffer from the Air. Then they ſhould be watered to ſettle the Earth to their Roots, and the Surface of the Ground ſhould be covered with Mulch, to prevent the Sun and Air from drying of their Roots; and if the Seaſon ſhould continue dry, it will be proper to water them twice a Week, but they ſhould not have too much Water given them each Time. When the Plants are well fixed in the Ground, they require no farther Care, but to keep them clear from large Weeds, which if permitted to grow, would overbear the Plants while they are young.

All theſe Sorts of *American* Pines ſhould be planted on a Soil rather moiſt than dry, but eſpecially the fourteenth Sort, which grows naturally on low moiſt boggy Places, and will not thrive on a dry Soil. This Tree hath a very remarkable Growth; for the Branches ſpread near the Ground to a great Diſtance from the Stem, and never riſe in Height. The thirteenth Sort is the moſt common in the Northern Parts of *America*, where the Inhabitants call it the *Jerſey-pine*.

As all the *European* Kind of Pines are Inhabitants of Mountains and Hills, ſo they delight in a hard rocky Soil, for which there are no Trees more proper; therefore whenever it happens in a large Plantation, that there is a low moiſt Place intervening between two Hills, that may be planted with theſe *American* Pines; ſo that the whole Plantation will appear, at a Diſtance, of the ſame Trees; and when nearer, the different Shades of their Leaves will diverſify the Proſpect; for which reaſon all theſe Sorts of Trees ſhould be propagated in the Nurſeries.

PISONIA, Fingrigo, *vulgo*.

The *Characters* are;

It is Male and Female in different Plants; the Male Flowers conſiſt of a great Number of Stamina, and have no Petals: the Female Flowers conſiſt of one Leaf, which is bell-ſhaped, and divided at the Top into five Parts: from whoſe Cup ariſes the Pointal, which afterward becomes an oblong angular chanelled Fruit, containing oblong Seeds.

The *Species* are;

1. PISONIA *aculeata mas. Houſt.* The Male Fingrigo.
2. PISONIA *aculeata, fructu glutinoſo & racemoſo. Plum. Nov. Gen.* Prickly Piſonia, with a glutinous and branching Fruit.

Theſe Plants are ſeminal Variations, which ariſe from the Seeds of the ſame Plant; but as they were not diſtinguiſhed by any of the Botaniſts, till the late Dr. *Houſtoun* obſerved their Difference, ſo I thought proper to mention the different Sexes as ſeparate Plants.

The Name of this Plant was given by Father *Plumier* in Honour to Dr. *William Piſo*, who publiſhed a Natural Hiſtory of *Braſil*. The Name of *Fingrigo* is what the Inhabitants of *Jamaica* know it by.

Theſe Plants are very common in the *Savanna*'s and other low Places in the Iſland of *Jamaica*, as alſo in ſeveral other Places in the *Weſt-Indies*; where it is very troubleſome to whoever paſſes thro' the Places of their Growth, by faſtening themſelves, by their ſtrong crooked Thorns, to the Cloaths of the Perſons; and their Seeds being glutinous, alſo faſten themſelves to whatever touches them. So that the Wings of the Ground Doves, and other Birds are often loaden with the Seeds, ſo as to prevent their Flying, by which means they become an eaſy Prey.

It riſes about ten or twelve Feet high, with a pretty ſtrong Trunk; but the Branches are long and ſlender, whereby being unable to ſupport themſelves, they generally twiſt about whatever Plants are near them.

In *Europe* this Plant is preſerved in the Gardens of ſome curious Perſons for Variety: it is propagated by Seeds which ſhould be ſown in Pots filled with light rich Earth and plunged into a Hot-bed of Tanners-bark; and when the Plants come up, they ſhould be tranſplanted into ſeparate Pots, and plunged into the Hot-bed again; where they may remain till *Michaelmas*, when they ſhould be removed into the Stove, and plunged into the Bark-bed, and treated in the ſame manner as hath been directed for ſeveral tender Plants of the ſame Country; obſerving in hot Weather to give them plenty of Water, but in Winter they ſhould have it more ſparingly. They are too tender to thrive in the open Air of this Country at any Seaſon of the Year, ſo ſhould be conſtantly kept in the Stove.

PISTACHIA, *vide* Terebinthus.

PISUM, [Some are of Opinion, that this Plant takes its Name from the City *Piſa*, where it anciently grew in great Plenty; others derive it from πίσειν, he fell, becauſe, if this Plant be not ſupported, it will fall to the Ground] Pea.

The *Characters* are;

It is a Plant with a papilionaceous Flower, out of whoſe Empalement riſes the Pointal, which afterwards becomes a long Pod, full of roundiſh Seeds; to which muſt be added, fiſtulous Stalks, for the moſt part weak, which the Leaves embrace in ſuch a Manner, that they ſeem to be perforated by them; but the other Leaves grow by Pairs along the Mid-rib, ending in a Tendril.

The *Species are*;

1. PISUM *hortenſe majus, flore fructuque albo. C. B. P.* The greater Garden Pea with white Flowers and Fruit.

2. Pisum *præcox Anglicum. Boerh. Ind.* Hot-ſpur Pea, *vulgo*.

3. Pisum *humile caule firmo. Tourn.* The Dwarf Pea.

4. Pisum *humile Gallicum. Boerh. Ind.* French Dwarf Pea.

5. Pisum *cortice eduli. Tourn.* Pea with an eſculent Husk.

6. Pisum *ſiliqua carnoſa incurva, ſeu falcata eduli. Raii Hiſt.* The Sickle Pea, *vulgo*.

7. Pisum *arvenſe, fructu albo. C. B. P.* Common white Pea.

8. Pisum *arvenſe, fructu viridi. C. B. P.* Green Rouncival Pea.

9. Pisum *arvenſe, fructu cinereo. C.B.P.* The Grey Pea.

10. Pisum *arvenſe, flore roſeo, fructu variegato. Raii Hiſt.* Maple Rouncival Pea.

11. Pisum *umbellatum. C. B. P.* The Roſe Pea or Crown Pea.

12. Pisum *maximum, fructu nigra linea maculato. H. R. Par.* The Spaniſh Morotto Pea.

13. Pisum *hortenſe, ſiliqua maxima. H. R. Par.* The Marrow-fat or Dutch Admiral Pea.

14. Pisum *fructu maximo ex viridi obſoleto. Boerh. Ind.* The Union Pea.

15. Pisum *ſpontaneum maritimum Anglicum. Park. Theat.* Engliſh Sea Pea.

16. Pisum *arvenſe, fructu e luteo vireſcente. C. B. P.* Pig Peas.

There are ſeveral other Varieties of the Garden *Peas*, which differ in the Colour of their Flowers and Fruit, and are by ſome Perſons diſtinguiſhed by Names as diſtinct Sorts; but as they are very ſubject to vary when ſown two or three Years in the ſame Place, ſo there can be no doubt of their being ſeminal Variations, which are not worth enumerating in this Place.

The *Engliſh Sea Pea*, is found wild upon the Shoar in *Suſſex*, and ſeveral other Counties in *England*; this was firſt taken notice of in the Year 1555, between *Orford* and *Aldborough*, where it grew upon the Heath, where nothing, no not Graſs, was ever ſeen to grow, and the poor People being in Diſtreſs, by Reaſon of the Dearth of that Year, gathered large Quantities of theſe *Peas*, and ſo preſerved themſelves and Families: This is mentioned by *Stow* in his *Chronicle*, and *Camden* in his *Britannia*. But they were both miſtaken, in imagining that they were *Peas* caſt on Shoar by a Shipwreck, ſeeing they grow in divers other Parts of *England*, and are undoubtedly a different Species from the common *Pea*.

The Sixteenth Sort is greatly cultivated in the Fields in *Dorſetſhire*, where they are known by the Name of *Pig-Peas*, the Inhabitants making great Uſe of them to feed their Hogs. Theſe are alſo often brought up to *London* and ſold for the ſame Purpoſe.

I ſhall now proceed to ſet down the Method of cultivating the ſeveral Sorts of Garden *Peas*, ſo as to continue them throughout the Seaſon.

It is a common Practice with the Gardeners near London, to raiſe *Peas* upon Hot-beds, to have them very early in the *Spring*, in order to which, they ſow their *Peas* upon warm Borders under Walls or Hedges, about the Middle of *October*; and when the Plants come up, they draw the Earth up gently to their Stems with a Hough, the better to protect them from Froſt; in theſe Places they let them remain until the Latter-end of *January*, or the Beginning of *February*, obſerving to earth them up from time to time as the Plants advance in Height (for the Reaſons before laid down) as alſo to cover them in very hard Froſt with Peas-haulm, Straw, or ſome other light Covering, to preſerve them from being deſtroy'd, then at the Time before-mention'd, they make a Hot-bed (in proportion to the Quantity of *Peas* intended) which muſt be well work'd in laying the Dung, that the Heat may not be too great: the Dung ſhould be laid about two Feet thick or ſomewhat more, according as the Beds are made earlier or later in the Seaſon; when the Dung is equally levelled, then the Earth (which ſhould be light and freſh, but not over rich) muſt be laid on about ſix Inches thick, laying it equally all over the Bed: This being done, the Frames (which ſhould be two Feet deep on the Back-ſide, and about fourteen Inches in Front) muſt be put on, and cover'd with Glaſſes, after which it ſhould remain three or four Days, to let the Steam of the Bed paſs off, before you put the Plants therein; obſerving every Day to raiſe the Glaſſes either with Bricks or Stones, to give Vent for the riſing Steam to paſs off; then when you find the Bed of a fine moderate Temperature for Heat, you ſhould with a Trowel, or ſome other Inſtrument, take up the Plants as carefully as poſſible, to preſerve a little Earth to their Roots, and plant them into the Hot-bed in Rows, about a Foot aſunder, and the Plants ſhould be ſet about an Inch and Half, or two Inches diſtance from each other in the Rows; obſerving to water and ſhade them until they have taken Root; after which you muſt be careful to give them Air, at all Times when the Seaſon is favourable, otherwiſe they will draw up very weak, and be ſubject to grow mouldy and decay. You ſhould alſo draw the Earth up to the Shanks of the Plants, as they advance in Height, and keep them always clear from Weeds; the Water they ſhould have, muſt be given them ſparingly, for if they are too much water'd, it will cauſe them to grow too rank, and ſometimes rot off the Plants at their Shanks, juſt above Ground; when the Weather is very hot, you ſhould cover the Glaſſes with Mats in the Heat of the Day, to ſcreen them from the Violence of the Sun, which is then too great for them, cauſing their Leaves to flag, and their Bloſſoms to fall off without producing Pods; as will alſo the keeping of the Glaſſes too cloſe at that Seaſon. But when the Plants begin to fruit, they ſhould be water'd oftener, and in greater Plenty than before; for by that Time the Plants will have nearly done growing, and the often refreſhing them will occaſion their producing a greater Plenty of Fruit.

The Sort of *Pea* which is always uſed for this Purpoſe, is the Dwarf; for all the other Sorts ramble too much to be kept in Frames: the Reaſon for ſowing them in the common Ground, and afterwards tranſplanting them on a Hot-bed, is alſo to check their Growth, and cauſe them to bear in leſs Compaſs; for if the Seeds were ſown upon a Hot-bed, and the Plants continued thereon, they would produce ſuch luxuriant Plants as not to be contained in the Frames, and would bear but little Fruit.

The next Sort of *Pea*, which is ſown to ſucceed thoſe on the Hot-beds, is the *Hot-ſpur*, of which there are reckon'd three or four Sorts, as the *Maſter's Hot-ſpur*, the *Reading Hot-ſpur*, and ſome others; which are very little differing from each other, except in their early Bearing, for which the *Maſter's Hot-ſpur* is chiefly preferr'd; tho' if either of theſe Sorts are cultivated in the ſame Place for three or four Years, they are apt to degenerate and be later in Fruiting, for which Reaſon moſt curious Perſons procure their Seeds annually from ſome diſtant Place, and in the Choice of theſe Seeds, if they could be obtained from a colder Situation, and a poorer Soil, than that in which they are to be ſown, it will be much better than on the contrary, and they will come earlier in the *Spring*.

Theſe muſt alſo be ſown on warm Borders, towards the Latter-end of *October*, and when the Plants are come up, you ſhould draw the Earth up to their Shanks in the Manner before directed, which ſhould be repeated as the Plants advance in Height (always obſerving to do it when the Ground is dry) which will greatly protect the Stems of the Plants againſt Froſt; and if the Winter ſhould prove very ſevere, it will be of great ſervice to the Plants, to cover them with Peas-haulm, or ſome other light Covering, which ſhould be conſtantly taken off in mild Weather, and only ſuffer'd to remain on during the Continuance of the Froſt; for if they are kept too cloſe, they will be drawn very weak and tender, and thereby be liable to be deſtroy'd with the leaſt Inclemency of the Seaſon.

In the *Spring* you muſt carefully clear them from Weeds, and draw ſome freſh Earth up to their Stems; but do not raiſe it too high to the Plants, leſt by burying their Leaves you ſhould rot their Stems, as is ſometimes the Caſe, eſpecially in wet Seaſons. You ſhould alſo obſerve to keep them clear from Vermin, which if permitted to remain amongſt the Plants, will increaſe ſo plentifully, as to devour the greateſt Part of them; the chief of the Vermin which infect *Peas*, are the *Slugs*, which lie all the Day in the ſmall Hollows of the Earth near the Stems of the Plants, and in the Night-time come out and make terrible Deſtruction of the *Peas*; and theſe chiefly abound in wet Soils, or where a Garden is neglected and over-run with Weeds; therefore you ſhould make the Ground clear every Way round the *Peas*, to deſtroy their Harbours, and afterwards in a fine, mild Morning very early, when theſe Vermin are got abroad from their Holes, you ſhould ſlack a Quantity of *Lime*, which ſhould be ſown hot over the Ground, pretty thick, which will deſtroy the Vermin, where-ever it happens to fall upon them; but will do very little Injury to the *Peas*, provided it be not ſcatter'd too thick upon them: This is the beſt Method I could ever find to deſtroy theſe troubleſome Vermin.

If this Crop of *Peas* doth hit, it will immediately ſucceed thoſe on the Hot-bed; but for fear this ſhould miſcarry, it will be proper to ſow two more Crops, at about a Fortnight diſtance from each other; ſo that there may be the more Chances to ſucceed: This will be ſufficient until the *Spring* of the Year, when you muſt ſow three more Crops of theſe *Peas*; one toward the latter End of *January*, and the other a Fortnight after, and the third at the End of *January*: Theſe two later Sowings will be ſufficient to continue the early Sort of *Peas* through the firſt Seaſon, and after this it will be proper to have ſome of the large Sorts of *Peas* to ſucceed them; in order to which, you ſhould ſow ſome of the *Spaniſh Morotto*, which is a great Bearer, and a hardy Sort of *Pea*, about the Middle of *February*, upon a clear open Spot of Ground; theſe muſt be ſown in Rows, about two Feet and a half aſunder, and the *Peas* ſhould be dropped in the Drills about an Inch and a half Diſtance, covering them about two Inches deep with Earth, being very careful that none of them lie uncovered, which will draw the Mice, Pigeons or Rooks to attack the whole Spot; and it often happens by this Neglect, that a whole Plantation is devoured by theſe Creatures; whereas when there are none of the *Peas* left in ſight, they do not ſo eaſily find them out.

About a Fortnight after this you ſhould ſow another Spot, either of this Sort or any other large Sort of *Pea* to ſucceed thoſe, and then continue to repeat ſowing once a Fortnight till the Middle or latter End of *April*, ſome of theſe Kinds, only obſerving to allow the *Marrow-fats*, and other very large Sorts of *Peas*, at leaſt three Feet between Row and Row; and the *Roſe-pea* ſhould be allowed at leaſt eight or ten Inches diſtance Plant from Plant in the Rows; for theſe grow very large, and if they have not Room allowed them, they will ſpoil each other, by drawing up very tall, and will produce no Fruit.

When theſe Plants come up, the Earth ſhould be drawn up to their Shanks (as was before directed) and the Ground kept entirely clear from Weeds; and when the Plants are grown eight or ten Inches high, you ſhould ſtick ſome rough Boughs or Bruſh Wood into the Ground, cloſe to the *Peas*, for them to ramp upon, which will ſupport them from trailing upon the Ground, which is very apt to rot the large growing Sorts of *Peas*, eſpecially in wet Seaſons; beſides, by thus ſupporting them, the Air can freely paſs between them, which will preſerve the Bloſſoms from falling off before their Time, and occaſion them to bear much better, than if permitted to lie upon the Ground; and there will be Room to paſs between the Rows to gather the *Peas* when they are ripe.

The Dwarf Sorts of *Peas* may be ſown much cloſer together than thoſe before-mentioned; for theſe ſeldom riſe above a Foot high, and rarely ſpread above half a Foot in Width; ſo that theſe need not have more Room than two Feet Row from Row, and about an Inch aſunder in the Rows. Theſe will produce a good Quantity of *Peas*, provided the Seaſon be not over dry; but they ſeldom continue long in bearing, ſo that they are not ſo proper to ſow for the main Crop, when a Quantity of *Peas* is expected for the Table; their chief Excellency being for Hot-beds, where they will produce a greater Quantity of *Peas* (provided they are well managed) than if expoſed to the open Air, where the Heat of the Sun ſoon dries them up.

The *Sickle-pea* is much more common in *Holland* than in *England*, it being the Sort moſtly cultivated in that Country; but in *England* they are only propagated by curious Gentlemen for their own Table, and are rarely brought into the Markets; this Sort the Birds are very fond of, and, if they are not prevented, do many times deſtroy the whole Crop. This ſhould be planted in Rows, about two Feet and a half aſunder, and be managed as hath been directed for the other Sorts.

The *Grey*, and other large *Winter-peas*, are ſeldom cultivated in Gardens, becauſe they require a great deal of Room, but are uſually ſown in Fields, in moſt Parts of *England*. The beſt Time for ſowing of theſe is about the Beginning of *March*, when the Weather is pretty dry; for if they are put into the Ground in a very wet Seaſon, they are apt to rot, eſpecially if the Ground be cold; theſe ſhould be allowed at leaſt three Feet Diſtance Row from Row, and muſt be ſown very thin in the Rows; for if they are ſown too thick, the Haulm will ſpread ſo as to fill the Ground, and ramble over each other, which will cauſe the Plants to rot, and prevent their Bearing.

The beſt Method to ſow theſe *Peas*, is, to draw a Drill with a Hough by a Line, about two Inches deep, and then ſcatter the Seeds therein, after which, with a Rake you may draw the Earth over them, whereby they will be equally covered; and this is a very quick Method for Gardens; but where they are ſown in Fields, they commonly make a ſhallow Furrow with the Plough, and ſcatter the Seeds therein, and then with a Harrow they cover them over again. After this, the great Trouble is to keep them clear from Weeds, and draw the Earth up to the Plants; this, in ſuch Countries where Labour is dear, is a great Expence, to do it by Hand with a Hough; but this may be eaſily effected with a Breaſt-houghing Plough, which may be drawn thro' between the Rows, which will entirely eradicate the Weeds, and by ſtirring of the Soil render it mellow, and greatly promote the Growth of the Plants.

When any of theſe Sorts are intended for Seed, there ſhould be as many Rows of them left ungathered, as may be thought neceſſary to furniſh a ſufficient Quantity of Seed; theſe muſt remain until their Pods are changed brown, and begin to ſplit; when you ſhould immediately gather them up together with the Haulm, and if you have not Room to ſtack them up until *Winter*, you may threſh them out ſo ſoon as they are dry, and put them up in Sacks for Uſe: But you muſt be very careful not to let them remain too long abroad after they are ripe, for if Wet ſhould happen, it would rot them, and Heat after a Shower of Rain, would cauſe their Pods to burſt and caſt forth their Seeds, ſo that the greateſt Part of them would be loſt; but, as I ſaid before, it is not adviſable to continue ſowing of the ſame Seed longer than two Years, for the Reaſons there laid down; but rather to exchange your Seeds every Year, or every two Years at leaſt, whereby you may always expect to have them prove well.

PISUM CORDATUM, *vide* Corindum.

PITTONIA.

The *Characters* are:

It hath a globular bell-ſhaped Flower, conſiſting of one Leaf, which is cut into ſeveral Segments at the Brim; from whoſe Cup ariſes the Pointal, which afterward becomes a ſoft ſpherical Berry full of Juice, incloſing two Seeds, which are for the moſt part oblong.

The *Species* are;

1. PITTONIA *arboreſcens chamædrifolia major. Plum. Nov. Gen.* Greater Tree-like *Pittonia*, with a Germander Leaf.

2. PITTONIA *arboreſcens chamædrifolia minor. Plum. Nov. Gen.* Smaller Tree-like *Pittonia*, with a Germander Leaf.

3. PITTONIA *humilis, anchuſæ foliis. Plum. Nov. Gen.* Dwarf *Pittonia*, with alkanet Leaves.

4. PITTONIA *ſcandens, baccis niveis, nigris maculis notatis. Plum. Nov. Gen.* Climbing *Pittonia*, with white Berries ſpotted with black.

5. PITTONIA *fruteſcens folio carnoſo, hirſuto & obtuſo. Plum. Nov. Gen.* Shrubby *Pittonia*, with a hairy fleſhy obtuſe Leaf.

6. PITTONIA *hirſutiſſima & ramoſiſſima, baccis albis. Plum. Nov. Gen.* The moſt hairy and branched *Pittonia*, with white Berries.

7. PITTONIA *racemoſa, nicotianæ foliis fœtidiſſimis. Plum. Nov. Gen.* The moſt ſtinking branchy *Pittonia*, with Tobacco Leaves.

Theſe Plants are all of them Natives of the warmeſt Parts of *America*, where the firſt Sort grows to the Height of twelve or fourteen Feet, and divides into many Branches, ſo as to form a ſmall Tree. The ſecond, fifth and ſeventh Sorts, grow to the Height of eight or nine Feet, and produce many Branches near their Roots, ſo as to form thick Buſhes.

They may be all propagated by Seeds, which ſhould be ſown early in the *Spring* in Pots filled with freſh Earth, and plunged into a Hot-bed of Tanners-bark; and when the Plants are come up, they may be treated after the ſame manner as hath been directed for the *Perſea*; with which Management theſe Plants will thrive very well, and in few Years will produce their Flowers. Theſe are preſerved by thoſe Perſons who are curious in collecting rare Plants, but there is no great Beauty in their Flowers; however, as they are ever-green, ſo they make a Diverſity amongſt other exotic Plants in the Stove in the *Winter* Seaſon.

PLANTA, a *Plant*, is defined by the ingenious Mr. *John Martyn* to be an organical Body, deſtitute of Senſe and ſpontaneous Motion, adhering to another Body in ſuch a manner as to draw from it its Nouriſhment, and having a Power of propagating itſelf by Seed. As to the Parts of which a Plant conſiſts, they are the Root, Stalk, Leaf, Flower, and Fruit.

Plant and Vegetable are pretty near Terms ſynonymous, all Plants being Vegetables. Dr. *Boerhaave* defines a Vegetabl getable to be a Body generated of the Earth, or of ſomething ariſing of the Earth, to which it adheres or is connected by Parts called *Roots*, through which it receives the Matter of its Nouriſhment and Increaſe; and conſiſts of Juices and Veſſels ſenſibly diſtinct from each other: Or a Vegetable is an organical Body, compoſed of Veſſels and Juices, every where diſtinguiſhable from each other; to which Body grow Roots or Parts whereto it adheres, and from which it derives the Matter of its Life and Growth.

This Definition furniſhes a juſt and adequate Idea of a Vegetable; for by *its conſiſting of Veſſels and Juices*, it is diſtinguiſhed from a Foſſil, and by *its adhering to another Body, and deriving its Nouriſhment therefrom*, it is diſtinguiſhed from an Animal.

A Vegetable is defined an *organical Body*, becauſe conſiſting of different Parts, which jointly concur to the Exerciſe of the ſame Function; *adhering by ſome of its Parts to another Body*, for we know of no Plant that is abſolutely vague and fluctuating, but has ſtill a Body it adheres to, tho' that Body may be various, *e.g. Earth*, as in our common Plants; *Stone*, as in Rock-plants; *Water*, as in Sea-plants; and *Air*, as in ſome Mucilages.

As to thoſe few Plants which appear to float in the Water, their manner of Growth is ſomething anomalous. M. *Tournefort* has ſhewn, that all Plants do not ariſe ſtrictly from Seeds, but that ſome, inſtead of Semen, depoſite or let fall a little Drop of Juice, which ſinking in the Water, reaches the Bottom, or ſome Rock, *&c.* in its Way, to which it ſticks, ſtrikes Root, and ſhoots into Branches; ſuch is the Origin of *Coral*. Add, that the Root of a Plant may have any Situation at Pleaſure, with reſpect to the Body thereof; nor needs it either be loweſt or higheſt, *&c.* accordingly in *Aloes*, *Coral*, *Moſſes*, *Fungus's*, &c. the Root is frequently uppermoſt, and its Growth downwards.

The Veſſels, or containing Parts of Plants, conſiſt of mere Earth, bound or connected together by Oil, as a Gluten, which being exhauſted by Fire, Air, Age, or the like, the Plant moulders, or returns again into its Earth or Duſt: Thus in Vegetables burnt by the intenſeſt Fire, the Earth or Matter of the Veſſels is left intire and indiſſoluble by its utmoſt Force; and conſequently the Matter thereof is neither Water, nor Air, nor Salt, nor Sulphur, but Earth alone.

The Root or Part whereby Vegetables are connected to their Matrix, and by which they receive their nutritious Juice, conſiſts of an infinite Number of abſorbent Veſſels, which being diſperſed thro' the Interſtices of the Earth, attract or imbibe the Juices of the ſame, conſequently every Thing in the Earth, that is diſſoluble in Water, is liable to be imbibed; as Air, Salt, Oil, Fumes of Minerals, Metal, *&c.* and of theſe Plants do really conſiſt.

Theſe Juices are drawn from the Earth very crude; but by the Structure and Fabrick of the Plant, and the various Veſſels they are ſtrained through, become changed, farther elaborated, ſecreted, and aſſimilated to the Subſtance of the Plant.

The Motion of the nutritious Juices of Vegetables is produced much like that of Blood in Animals, by the Action of the Air; in effect, there is ſomething equivalent to Reſpiration throughout the whole Plant.

The Diſcovery of this we owe to the admirable *Malpighi*, who firſt obſerved that Vegetables conſiſt of two Series or Orders of Veſſels; firſt, ſuch as receive and convey the alimental Juices, anſwering to the Arteries, Lacteals, Veins, *&c.* of Animals; ſecondly, *Tracheæ*, or *Air Veſſels*, which are long, hollow Pipes, wherein Air is continually received and expelled, *i. e.* inſpired and expired; within which *Tracheæ* he ſhews all the former Series of Veſſels are contained.

Hence it follows, that the Heat of a Year, nay, of a Day, of a ſingle Hour or Minute, muſt have an Effect on the Air included in theſe *Tracheæ*, *i. e.* muſt rarefy it, and conſequently dilate the *Tracheæ*, whence ariſes a perpetual Spring or Source of Action to promote the Circulation in Plants.

PLANTAIN TREE, *vide* Muſa.

PLANTING. Although the Method of *Planting* the various Sorts of Trees, is fully ſet down under the ſeveral Articles where each Kind is mentioned, yet it may not be amiſs to ſay ſomething in general upon that Head in this Place; which ſhall be ſet down as briefly as poſſible. And,

Firſt, The firſt Thing in the *Planting* of Trees, is to prepare the Ground (according to the different Sorts of Trees you intend to plant) before the Trees are taken out of the Earth; for you ſhould ſuffer them to remain as little Time out of the Ground as poſſible.

In taking up the Trees, you ſhould carefully dig away the Earth round their Roots, ſo as to come at their ſeveral Parts to cut them off; for if they are torn out of the Ground without Care, the Roots will be broken and bruiſed very much, to the great Injury of the Trees. When you have taken them up, the next Thing is to prepare them for *Planting*, in doing of which there are two Things to be principally regarded; the one is to prepare the Roots, and the other to prune their Heads, in ſuch a Manner as may be moſt ſerviceable in promoting the future Growth of the Trees.

And firſt, as to the Roots; all the ſmall Fibres are to be cut off, as near to the Place from whence they are produced, as may be, (excepting ſuch Trees as are to be replanted, immediately after they are taken up) otherwiſe the Air will turn all the ſmall Roots and Fibres black; which if permitted to remain on, when the Tree is planted, will grow mouldy and decay, and thereby ſpoil all the new Fibres which are produced; ſo that many times the Trees miſcarry for Want of duly obſerving this: After the Fibres are all cut off, you ſhould prune off all the bruiſed or broken Roots ſmooth, otherwiſe they are apt to rot and diſtemper the Trees; you ſhould alſo cut out all irregular Roots which croſs each other, and all downright Roots (eſpecially in Fruit Trees) muſt be cut off; ſo that when the Roots are regularly pruned, they may in ſome meaſure reſemble the Fingers of a Hand, when ſpread open; then you ſhould ſhorten the larger Roots, in Proportion to the Age and Strength of the Tree; as alſo the particular Sorts of Trees are to be conſidered, for the *Walnut*, *Mulberry*, and ſome other tender-rooted Kinds ſhould not be pruned ſo cloſe, as the more hardy Sorts of Fruit or Foreſt Trees, which in young Fruit Trees, ſuch as *Pears*, *Apples*, *Plums*, *Peaches*, &c. that are one Year old, from budding or grafting, may be left about eight or nine Inches long; but in older Trees they muſt be left of a much greater Length; but this is to be underſtood of the larger Roots only, for the ſmall ones muſt be chiefly cut quite out, or pruned very ſhort, their extream Parts, which are generally very weak, do commonly decay after moving, ſo that it is the better Way intirely to diſplace them.

The next Thing is the pruning of their Heads, which muſt be differently performed in different Trees, and the Deſign of the Trees muſt alſo be conſidered; for if they are intended for Walls or Eſpaliers, it is the better Way to plant them with the greateſt Part of their Heads, which ſhould remain on until the *Spring*, that the Trees begin to ſhoot, when they muſt be cut down to five or ſix Eyes (as is fully ſet down in the ſeveral Articles of the various Kinds of Fruit) being very careful in doing of this, not to diſturb the new Roots.

But if the Trees are deſigned for Standards, you ſhould prune off all the ſmall Branches cloſe to the Places where they are produced, as alſo irregular Branches which croſs each other, and by their Motion when agitated by the Wind, do rub and bruiſe each other, ſo as to occaſion many times great Wounds in thoſe Places; beſides, it makes a diſagreeable Appearance to the Sight, and adds to the cloſeneſs of its Head, which ſhould always be avoided in Fruit Trees; whoſe Branches ſhould be preſerved as far diſtant from each other, as they are uſually produced when in a regular Way of Growth (which is in all Sorts of Trees proportionable to the Size of their Leaves, and Magnitude of their Fruit) for when their Heads are very thick, which is often occaſioned by the unſkilful ſhortening of their Branches, the Sun and Air cannot freely paſs between their Leaves, ſo that the Fruit muſt be ſmall and ill-taſted. But to return: After having diſplaced theſe Branches, you ſhould alſo cut off all ſuch Parts of Branches as have by any Accident been broken or wounded; for theſe will remain a diſagreeable Sight, and often occaſion a Diſeaſe in the Tree. But you ſhould, by no Means, cut off the main, leading Shoots, as is by too many practiſed, for thoſe are neceſſary to attract the Sap from the Root, and thereby promote the Growth of the Tree: For, from ſeveral Experiments which I made the *Winter* 1729, by cutting off the Branches of ſeveral Sorts of Trees, and putting them into Phials filled with Water, whoſe Tops were cloſely covered, to prevent the evaporating of the Water, I found, that thoſe Shoots whoſe leading Buds were preſerved, did attract the Moiſture in much greater Quantity than thoſe Shoots whoſe Tops were cut off: And from ſeveral Experiments made by the Reverend Dr. *Hales*, we find, that great Quantities of Moiſture are imbibed at Wounds, where Branches are cut off; ſo that by thus ſhortening the Branches, the Wet, which generally falls in great Plenty during the *Winter* Seaſon, is plentifully imbibed, and for Want of Leaves to perſpire it off, mixes with the Sap of the Trees, and thereby diſtending the Veſſels, deſtroys their contracting Force, which many times kills the Tree, or at leaſt weakens it ſo much, as not to be recovered again for ſome Years, as I have ſeveral times obſerved.

But being willing to try the Experiment in the Month of *October* 1723, I made choice of two Standard Almond Trees of equal Strength and Age; theſe I took up as carefully as poſſible, and having prepared their Roots, as before directed, I pruned their Heads in the following Manner, *viz.* Of one of them I only cut off the ſmall Branches, and ſuch as were bruiſed or broken, but preſerved all the ſtrong ones intire: Of the other I ſhortened all the ſtrong Branches, and pruned off the weak and broken Shoots, as is the common Practice. Theſe two Trees I planted in the ſame Soil, and to the ſame Situation, gave them both equal Attendance, and managed them both as nearly alike as poſſible; yet, in the *Spring*, when theſe Trees began to ſhoot, that whoſe Branches were intirely preſerved, came out early, continued to ſhoot ſtronger, and is at preſent much larger, and in better Health than the other. And ſince this, I have made ſeveral other Experiments of the like Nature, which have conſtantly ſucceeded in the ſame Manner; from whence it is reaſonable to conclude, that the ſhortening of the Branches is a great Injury to all new-planted Trees.

Having thus prepared the Trees for *Planting*, we muſt next proceed to the placing them into the Ground; but before this, I would adviſe, if the Trees have been long out of the Ground, ſo that their Fibres are dry'd, to place their Roots in Water eight or ten Hours, before they are planted, obſerving to place them in ſuch a manner that their Heads may remain erect, and their Roots only immerſed therein, which will ſwell the dried Veſſels of the Roots, and prepare them to imbibe Nouriſhment from the Earth. In fixing of them, great Regard ſhould be had to the Nature of the Soil, which, if cold and moiſt, the Trees ſhould be planted very ſhallow; as alſo, if it be a hard Rock or Gravel, it will be much the better Way to raiſe a Hill of Earth where each Tree is to be planted, than to dig into the Rock or Gravel, and fill it up with Earth, (as is too often practiſed) whereby the Trees are planted, as it were, in a Tub, there being but little Room for their Roots to extend; ſo that after two or three Years Growth, when their Roots have extended to the Sides of the Hole, they are ſtopped by the Rock or Gravel, can get no farther, and the Trees will decline, and in a few Years die; beſides, theſe Holes do detain the Moiſture ſo that the Fibres of the Plants are often rotted thereby. But when they are raiſed above the Surface of the Ground, their Roots will extend and find Nouriſhment, though the Earth upon the Rock or Gravel be not three Inches thick, as may be frequently obſerved, where Trees are thus placed.

The next Thing to be obſerved is, to place the Tree in the Hole in ſuch manner, that the Roots may be about the ſame Depth in the Ground as they were growing before they were taken up: Then break the Earth fine with a Spade, and ſcatter it into the Hole, ſo that it may fall in between every Root, that there may be no Hollowneſs in the Earth, (but you ſhould by no Means ſift or ſcreen the Mould, for Reaſons given in the Article of *Firrs*) then having filled in the Earth, you ſhould gently tread it cloſe with your Feet; but do not make it too hard; which is a very great Fault, eſpecially if the Ground be ſtrong or wet.

Having thus planted the Trees, you ſhould provide a Parcel of Stakes, which ſhould be drove down by the Sides of the Trees, and faſtened thereto to ſupport them from being blown down, or diſplaced by the Wind; and then lay ſome Mulch upon the Surface of the Ground, about their Roots, to prevent the Earth from drying.

This is to be underſtood of Standard Trees which caſt their Leaves; and as to ſuch as are planted againſt Walls, there is no other Difference in their Management, but only to preſerve their Heads intire, and to place their Roots about five or ſix Inches from the Wall inclining their Heads thereto; which ſhould be faſtened to the Wall, to prevent their being diſplaced by the Wind; and in the *Spring* following, juſt before they ſhoot, their Heads ſhould be cut down to five or ſix Buds, as is fully directed under the ſeveral Articles of the different Kinds of Fruit.

As to the Watering of all new-planted Trees, I ſhould adviſe it to be done with great Moderation; nothing being more injurious to them than over-watering of them; Examples enough of this Kind may have been ſeen in St. *James's* Park a few Years paſt, where there have been many Trees planted to make the Rows complete, where the old Trees were decay'd; and notwithſtanding the great Care in bringing in a large Quantity of freſh Earth, where each Tree was *planted*, yet very few of them have taken, and thoſe few which are yet alive, have made but poor Progreſs, nor will they ever be thriving Trees; which is wholly owing to the Abundance of Water given to them, whereby the Fibres are rotted off as ſoon as they are produced. And how can any Perſon imagine, that a Tree ſhould thrive, when the Ground in which it is *planted*, is continually floated with Water? For, by an Experiment made by the Reverend Dr. *Hales*, in placing the Roots of a *Dwarf Pear-Tree* in Water, the Quantity of Moiſture imbibed decreas'd very much daily, becauſe the Sap-Veſſels of the Roots, like thoſe of the cut-off Boughs in the ſame Experiment, were ſo ſaturated and clogged with Moiſture, by ſtanding in Water, that more of it could not be drawn up. And this Experiment was tried upon a Tree which was full of Leaves, and thereby more capable to diſcharge a large Quantity of Moiſture, than ſuch Trees as are intirely deſtitute of Leaves; ſo that it is impoſſible ſuch Trees can thrive, where the Moiſture is too great about their Roots.

The Seaſons for *Planting* are various, according to the different Sorts of Trees or the Soil in which they are *planted*: For ſuch Trees whoſe Leaves fall off in *Winter*, the beſt time is the Beginning of *October*, provided the Soil be dry; but for a wet Soil, it is better to defer it until the Latter-end of *Februray*, or the Beginning of *March*; and for Ever-greens, the Beginning of *April* is, by far, the beſt Seaſon, though they may be ſafely remov'd at *Midſummer*, provided they are not to be carried very far; but you ſhould always make Choice of a cloudy, moiſt Seaſon, if poſſible, when they will take freſh Root in a few Days. And, on the contrary, when theſe Trees are removed in *Winter*, during which Time they are almoſt in a State of Reſt, they do not take Root until the *Spring* advances, and ſets the Sap in Motion, ſo that many times they die, eſpecially if the *Winter* proves ſevere.

As to the preparing the Soil for *Planting*, that muſt alſo be done to ſuit the different Sorts of Trees, ſome requiring a light Soil, others a ſtrong one, &c. But this is fully ſet down in the ſeveral Articles of Trees, under their proper Heads, to which the Reader is deſired to turn; though for Fruit-Trees in general a freſh Soil from a Paſture-Ground, which is neither too light and dry, nor over ſtrong and moiſt, but rather a gentle, ſoft, loamy Earth, is to be preferr'd. And if it be for Wall Trees, it will be the better if the Borders are fill'd with this Earth ſix Feet wide, but it need not be above eighteen Inches or two Feet deep at moſt; for when the Borders are made too deep, the Roots of theſe Trees are inticed downward, which is of bad Conſequence to Fruit-Trees, as hath been elſewhere obſerved. The ſame alſo muſt be obſerved for Standard Trees, (where freſh Earth is brought to the Places in which they are *planted*) not to make the Holes too deep, but rather let them have the ſame Quantity of Earth in Width, which is much to be preferr'd.

There are ſeveral Perſons who direct the Placing of the ſame Side of the Tree to the South, which, before removing, had that Poſition, as a material Circumſtance to be ſtrictly regarded; but from ſeveral Trials which I have made, I could not obſerve the leaſt Difference in the Growth of thoſe Trees which are ſo placed, and others which were reverſed; ſo that I conclude it is not of any Conſequence to obſerve this Method.

The Diſtance which Trees ſhould be *planted* at, muſt alſo be proportioned to their ſeveral Kinds, and the ſeveral Purpoſes for which they are intended; all which is explain'd under their ſeveral Heads; but Fruit-Trees, *planted* either againſt Walls, or for Eſpalliers, ſhould be allowed the following Diſtances. For moſt Parts of vigorous-ſhooting *Pear-Trees*, twenty four Feet; for *Apricocks*, ſixteen Feet; *Apples*, ſixteen Feet; *Peaches*, *Nectarines*, *Cherries*, and *Plums*, fourteen or ſixteen Feet, according to the Goodneſs of the Soil, or the Height of the Wall. But as theſe Things are mention'd in their ſeveral Articles, it will be needleſs to repeat any more in this Place.

PLANTING REVERSE: Dr. *Agricola* tells us, That he has made ſeveral Experiments on the Branches of Foreig Trees, as well *Orange* as *Laurel*, which he perform'd afte the Manner following: He firſt ſtripp'd the Branches of al the Leaves, then he bent and tyed them, dreſs'd them wit his noble Mummy, and *planted* them the *reverſe* Way; ſ that nothing was to be ſeen of all the Branches, but th great Ends, and kept them, during the *Winter* in hi Stove.

He adds, That thoſe who have a mind to raiſe Trees this Way, which he calls *Monſtrous Fruit-Trees*, may raiſe *Apples*, *Pears*, *Cherries*, *Apricocks*, *Peaches*, *Mulberries*, *Walnut-Trees*, &c. alſo *Roſe-Trees*, *Gooſeberry Buſhes*, &c. which he directs to do ſomething more at large, as follows:

Take thoſe Branches that are furniſhed with long Side Branches, or Twigs, and bend the Side-Twigs in the Joints towards the great Branches and tie them together with Baſs or Packthread; then dreſs them with Mummy, either with a Bruſh only near the Ligature, and here and there on the Joints, or dip them intirely into it: Then having made a deep Hole in the Ground, ſet the Branches the *reverſe* Way, ſo that nothing but the long End of the Branch appears above Ground, the reſt being covered with good, fat, and well-ſifted Earth. This being done, the little Branches will take Root in the Joints every where; then the Buds will begin to ſhoot, ſo that you may ſee fifty or ſixty more Branches ſpring up, making an agreeable as well as monſtrous Figure.

Mr. *Fairchild* of *Hoxton* had begun to put the ſame into Practice, and he himſelf gives Directions for performing it as follows:

Firſt, to make Choice of a young Tree of one Shoot, either of *Alder*, *Elm*, or *Willow*, or any other Tree that will take Root eaſily by Laying, and to bend that Shoot gently down the extreme Part in the Earth, and ſo to let it remain 'till it has taken Root, ſo that the *Plant* then will reſemble an Arch, or bent Bow above the Ground.

When this Top End has well ſtruck new Roots, to dig about the firſt Root, and raiſe it gently out of Ground, 'till the Stem inclines to an Upright, and ſo ſtake it up, otherwiſe it will incline to bend.

Then to prune thoſe Roots that are erected in the Air, from the Bruiſes and Wounds which they receiv'd in being dug up, and do over with a Bruſh the prun'd Parts with the following Compoſition, moderately warm.

Take four Ounces of Tallow, four Ounces of Bees-Wax, two Ounces of Roſin, and two Ounces of Turpentine, melted together in a Pipkin.

After this prune off all the Buds or Shoots that are upon the Stem or *Plant*, and dreſs the Wound with the ſame Compoſition, to prevent any collateral Shootings, that may ſpoil the Beauty of the Stem.

Beſides, Care is to be taken that the new growing Roots of this *revers'd Plant* be well nouriſh'd, and therefore that Part of the Shoot, which was the larger, is to be cut away a little below the Earth, that the Stem may be better nouriſhed, and its Roots tranſlated.

PLATANUS, [πλάτανος of πλάτος, *breadth*] The Plane-Tree.

The *Characters* are;

It hath an amentaceous Flower, conſiſting of ſeveral ſlender Stamina, which are collected into ſpherical little Balls, and are barren; but the Embryo's of the Fruit, which are produced on ſeparate Parts of the ſame Tree, are turgid, and do afterwards become large ſpherical Balls, containing many oblong Seeds, intermix'd with Down.

The *Species* are;

1. PLATANUS *Orientalis verus. Park. Theat.* The true Oriental *Plane-Tree.*
2. PLATANUS *Occidentalis aut Virginienſis. Park. Theat.* The Weſtern or Virginian *Plane-Tree.*
3. PLATANUS *Orientalis aceris folio. T. Cor.* The Maple-leav'd *Plane-Tree.*
4. AN PLATANUS *Americanus, foliis oblongis ex adverſo naſcentibus.* The Button-Tree, *vulgo.*

The firſt of theſe Trees (though the firſt known Sort in *Europe*) is leſs common than the ſecond; which has been introduced ſince the *Engliſh* ſettled in *Virginia*; which may be, in a great meaſure, owing to the latter Sort being much eaſier to propagate than the former; for ever Cutting of this, if planted in a moiſt Soil, juſt before the Tree begins to ſhoot, will take Root, and in a few Years make very large Trees; whereas the firſt is only propagated from Seeds or by Layers.

The third Sort, although by ſome ſuppos'd to be a diſtinct Species from either of the former, yet is no more but a ſeminal Variety of the firſt; for I have had many Plants which came up from the Seeds of the firſt Sort, which ripen'd in the *Phyſick-Garden*, which do moſt of them degenerate to this third Sort, which in the manner of its Leaves, ſeems to be very different from either, and might reaſonably be ſuppos'd a diſtinct Sort, by thoſe who have not traced its Original.

The fourth Sort here mention'd was ſent from *Carolina*, by the Name of *Button-Tree*, and by the Account ſent with it, ſeems to be a Sort of *Plane-Tree*, though the Manner of this Tree's growing is very different from any of the other Sorts; but as it hath not produced either Flowers or Fruit in *England*, ſo I cannot determine whether it be a true *Plane-Tree* or not.

Theſe Trees delight to grow on a moiſt, rich Soil, on which they will arrive to a prodigious Size in a few Years, and during the *Summer* Seaſon do afford a glorious Shade; their Leaves being of a prodigious Size, eſpecially on a good Soil, ſo that there is ſcarcely any Tree at preſent in *England*, which does afford ſo good a Shade. But the Backwardneſs of their coming out in *Spring*, together with their Leaves fading early in *Autumn*, has occaſioned their not being ſo generally eſteem'd, as otherwiſe they would be.

The firſt Sort was brought out of the *Levant* to *Rome*, where it was cultivated with much Coſt and Induſtry: The greateſt Orators and Stateſmen among the *Romans*, took great Pleaſure in their *Villa's* which were ſurrounded with *Platanus*; and their Fondneſs to this Tree became ſo great, that we frequently read of their *irrigating* them with *Wine* inſtead of *Water*. *Pliny* affirms, that there is no Tree whatſoever which ſo well defends us from the Heat of the Sun in *Summer*, nor that admits it more kindly in *Winter*, for the Branches being produced at a proportionable Diſtance, to the Largeneſs of their Leaves, (which is what holds through all the different Sorts of Trees yet known) ſo that when the Leaves are fallen in *Winter*, the Branches growing at a great Diſtance, do eaſily admit the Rays of the Sun.

This Tree was afterwards brought to *France*, where it was cultivated only by Perſons of the firſt Rank; and ſo much was the Shade of it priz'd, as that if any of the Natives did but put his Head under it, they exacted a Tribute from them.

It is generally ſuppos'd, that the Introduction of this Tree into *England*, is owing to the great Lord Chancellor *Bacon*, who planted a noble Parcel of them at *Verulam*, which were there, very flouriſhing, a few Years ſince. But notwithſtanding its having been ſo long in *England*, yet there are but few very large Trees to be ſeen of it at preſent; which may, perhaps, be owing to the great Eſteem the Perſons of the laſt Age had for the *Lime*, which being much eaſier to propagate, and of quicker Growth during the three or four firſt Years, than the *Plane-Tree*, thereby it became the moſt common Tree for Planting of Avenues and ſhady Walks near Habitations in *England*. But ſince the Defects of that Tree have been more generally diſcovered, the *Elm* has had the Preference, and is now the moſt commonly planted for ſuch Purpoſes.

However, notwithſtanding what has been ſaid of the *Plane-Tree*, of its Backwardneſs in coming out in the *Spring*, and the ſudden Decay of its Leaves in *Autumn*, yet, for the goodly Appearance, and great Magnitude to which it will grow, it deſerves a Place in large Plantations, or ſhady Receſſes near Habitations, eſpecially if the Plantation be deſign'd on a moiſt Soil, or near Rivulets of Water; in which Places this Tree will arrive to a prodigious Magnitude.

We read of one of theſe Trees which was growing at a *Villa* of the Emperor *Caligula*, whoſe Trunk was ſo large, as, when hollow'd, to make a Room, therein capacious enough to entertain ten or twelve Perſons at a Repaſt, and for their Servitors to wait upon them. And there is Mention made of one of theſe Trees, which was growing in the *Eaſtern* Country, which was of ſo great a Magnitude, that *Xerxes* made his Army (which conſiſted of ſeventeen hundred thouſand Men) halt, for ſome Days, to admire the Beauty and Procerity of this Tree; and became ſo fond of it, as to take his own, his Concubines, and all the great Perſons Jewels to cover it; and was ſo much enamour'd with it, that for ſome Days, neither the Concern of his Grand Expedition, nor Intereſt, nor Honour, nor the neceſſary Motion of his prodigious Army could diſſuade him from it: He ſtyl'd it, His Miſtreſs, His Minion, His Goddeſs; and when he was obliged to part with it, he cauſed a Figure of it to be ſtamp'd on a Gold Medal, which he continually wore about him.

And ſuch was the Eſteem which the People of *Aſia* had for this Tree, that where-ever they erected any ſumptuous Buildings, the Portico's, which open'd to the Air, terminated in Groves of theſe Trees.

The *Eaſtern Plane-Tree* is propagated either from Seeds or by Layers, the latter of which is generally practis'd in *England*; though the Plants thus rais'd do ſeldom make ſo large, ſtrait Trees, as thoſe which are produc'd from Seeds; but it has been generally thought, that the Seeds of this Tree were not productive, becauſe they have not been ſown at a proper Seaſon, nor managed in a right Manner; for I have had thouſands of the young Plants ſpring up from the Seeds of a large Tree, which ſcatter'd upon the Ground in a moiſt Place: And I ſince find, that if theſe Seeds are ſown ſoon after they are ripe, in a moiſt ſhady Situation, they will riſe extremely well; and the Plants thus obtain'd, will make a conſiderable Progreſs after the ſecond Year, being much hardier, and leſs liable to loſe their Tops in *Winter*, than thoſe which are propagated by Layers. And ſince the Seeds of this Tree ripen well in *England*, they may be propagated in as great Plenty as any other Foreſt Tree.

The *Virginian Plane-Tree* will grow extremely well from Cuttings, if they are planted the Beginning of *March* upon a moiſt Soil; and if they are water'd in dry Weather, will make a prodigious Progreſs. So that in a few Years from the Planting, they will afford noble Trees for planting of Avenues, and other ſhady Walks; and their Trunks are perfectly ſtrait, growing nearly of the ſame Size to a conſiderable Height, there being the leaſt Difference in the Girt of this Tree, for ſeveral Yards upwards, of any other Sort of Tree whatſoever. The Honourable *Paul Dudley*, Eſq; in a Letter to the *Royal Society*, mentions one of theſe Trees, which he obſerved in *New-England*, whoſe Girt was nine Yards, and held its Bigneſs a great Way up; which Tree, when cut down, made twenty-two Cords of Wood. He alſo ſays, in the ſame Letter, That he has propagated many of theſe Trees by cutting off Sticks of five or ſix Feet long, and ſetting them a Foot deep into the Ground in the *Spring* of the Year, when the Seaſon was wet; and that they always thrive beſt in a moiſt Soil.

The Leaves of this Sort are larger, and leſs divided than thoſe of the *Oriental Plane-Tree*; and the Tree grows much faſter, and is hardier, and being thus eaſily propagated, is now the moſt common in *England*.

The *Maple-leav'd Plane-Tree* hath its Leaves leſs divided than the firſt, but more than the ſecond Sort, ſo that it is a middle Kind between both; tho', as I before ſaid, it comes originally from the *Eaſtern* Sort.

This is propagated very eaſily by Layers, every Twig of which will take Root, if they are but cover'd with Earth; and when tranſplanted out in a moiſt Soil, will grow equally faſt with the *Virginian* Kind. But whether this will take from Cuttings or not, I cannot ſay, having never made Trial of it; though from the Readineſs of the Branches taking Root, there is little Reaſon to doubt of it. The beſt time to tranſplant theſe Trees is in *March*; for if they are removed in *Winter*, and the Seaſon ſhould prove very ſevere, the tender Shoots are often kill'd by the Froſt.

PLINIA.

The *Characters* are;

It hath a bell-ſhaped Flower conſiſting of one Leaf, which is divided into five Segments at the Brim; from whoſe Cup riſes the Pointal, which afterward becomes a globular, ſoft, chanelled Fruit, in which is included one Seed of the ſame Form.

We have but one *Species* of this Plant, which is;

PLINIA *fructu croceo odorato. Plum. Nov. Gen.* Plinia with a ſweet-ſcented ſaffron-coloured Fruit.

This Plant was diſcovered by Father *Plumier* in the *Weſt-Indies*, who gave it this Name, in Honour to *Pliny* the famous *Natural Hiſtorian*.

It grows in ſeveral Places in the warmer Parts of *America*, from whence the Seeds have been ſent to *Europe*. Theſe Seeds muſt be ſown in Pots filled with light rich Earth, and plunged into a Hot-bed of Tanners-bark, obſerving to moiſten the Earth with Water whenever it appears dry, as alſo to preſerve a moderate Temperature of Heat in the Bed, ſo that if the Nights ſhould prove cold, the Glaſſes of the Hot-bed ſhould be every Night covered with Mats; and in the middle of the Day the Glaſſes may be raiſed to admit freſh Air, when the Weather is warm. Theſe Seeds will ſometimes remain long in the Ground before the Plants appear; and whenever it ſo happens, the Pots muſt be conſtantly kept clear from Weeds, and duly watered. And when the Plants come up, they ſhould be tranſplanted into Pots, and may be managed as is directed for the *Pittonia*.

PLOUGHING of Land.

There is not a greater Improvement of arable Land, than that of well ploughing it; by which Method the Soil is pulveriſed, and rendered fit to receive the Fibres of Plants. And the oftener this is repeated, the greater Improvement is made. But as this part of Agriculture has been fully treated of by the ſeveral Writers on Husbandry, I ſhall not repeat what they have ſaid, but ſubjoin a few Remarks to thoſe already publiſhed.

In ploughing of Land, great Regard ſhould be had to the Crop which is deſigned to be ſown; for if the Plants have Tap-roots, which run deep into the Ground, then it ſhould be ploughed deep; otherwiſe, when the Roots have reached ſo low as to meet with the unſtirred Earth, they will ſtop, and divide into ſmall forky Roots, and be good for little. It has been often aſſerted, that deep ploughing is very injurious to many Soils; but from repeated Obſervations it appear otherwiſe; for where-ever there is Depth enough of Soil to admit of deep ploughing, when it is practiſed rightly, it is a vaſt Improvement to the Land. Indeed, where the Land is very ſtubborn, and ploughed ſo deep as to turn up the ſtrong part on the Surface, and this is not well wrought to divide the Parts, it often proves a Diſadvantage to the Crop; but when this is practiſed, it ſhould always be done the Beginning of Winter, ſo that it may be expoſed to the Froſt, which will be of great Uſe, by entering of the Clods, and cauſing them to crumble after the Thaw; then in the Spring it ſhould be again ploughed, and this repeated twice more at leaſt the following Summer, which will not only deſtroy the Weeds, but ſo divide the Particles of Earth, as to make it fall eaſily under the Harrow.

The Difference between Land which is dug by hand, and that which is ploughed, conſiſts in having the Parts more divided; ſo that every Perſon who is curious in Working of his Land, will oblige his Labourers to take as thin Spits of Earth as poſſible, that there may remain no large Clods unbroken. And it is the ſame in ploughing; for if the Land is ploughed three or four times carefully, it will divide the Clods equal to the Land which is dug, and will ſufficiently repay the Husbandman. But this is not to be done with the common Plough, for that will not divide the Parts, therefore the Plough with four Coulters; ſhould be uſed for this purpoſe. As this Sort of Plough requires more Strength to draw it, ſo it ſhould not be uſed but in wet Weather; for when the Ground is moiſt, this Plough may be more eaſily drawn, than when it is dry and hard; and there is no Danger of injuring the Land, by ploughing in wet Weather with this Plough, tho' there is much in the common Plough at ſuch times; becauſe, when the Furrow is turned over whole, the Clods will cement with the Wet; and where the Cattle tread on it, the Ground will be rendered as hard as before it was ſtirred.

It hath been a Practice in ſome Countries, where the Land is mellow, to plough the Top of the Furrow, and then with ſix or ſeven Labourers to dig after the Plough, and throw the Earth on the Top, which is almoſt equal to digging of the Land two Spits deep, and is performed at a much eaſier Expence: but this is never practiſed, except for ſome particular Crops, which root very deep in the Ground.

The Models or Draughts of all the Sorts of Ploughs in Uſe being already exhibited in the ſeveral Books of Husbandry extant, I ſhall not give any farther Account of them.

PLUMBAGO; [This Plant is ſo call'd, becauſe its Leaves are of a Leaden Colour, and becauſe it colours the Hands of thoſe that handle it of a leaden Colour: In like manner, it is call'd *Molydana*, of μόλυβδος, *Lead*: It was alſo call'd *Dentillaria* by the Ancients, becauſe its Roots not only reſemble a Tooth, but becauſe it is alſo good for the Tooth-ach] Lead-wort.

The *Characters* are;

The Flower conſiſts of one Leaf, which is ſhap'd like a Funnel, and cut into ſeveral Segments at the Top; out of whoſe fiſtulous Flower-cup riſes the Pointal, which afterwards becomes one oblong Seed, for the moſt part ſharp-pointed, which ripens in the Flower-cup.

The *Species* are;

1. PLUMBAGO *quorundam. Cluſ. Hiſt.* Lead-wort, or Tooth-wort.

2. PLUMBAGO *Americana, betæ folio ampliori. Plum.* American Lead-wort, with a broad Beet-leaf.

3. PLUMBAGO *flore albo. Inſt. R. H.* Leadwort with a white Flower.

4. PLUMBAGO *Orientalis, lapathi folio, flore minori albido. Tourn. Cor.* Eaſtern Leadwort, with a dock Leaf, and a ſmaller whitiſh Flower.

5. Plumbago *Americana ſcandens aculeata, betæ folio minori. Plum. Cat.* Prickly Climbing *American* Leadwort, with a leſſer Beet-leaf.

The firſt of theſe Sorts grows about *Naples*, in *Sicily*, and the Southern Parts of *France*, but is hardy enough to endure the Cold of our Climate in the open Ground, provided it be planted in a warm dry Soil. This is propagated by parting of the Roots in the *Spring* before they ſhoot: In doing of which, you ſhould be very careful to preſerve a Head to each Slip, otherwiſe they will not grow. They ſhould be planted in a warm Situation, and a dry Soil, about two Feet aſunder, and water'd until they take Root; after which they will require no farther Care, but to clear them from Weeds, and ſupport their Branches from being broken by the Wind. They commonly riſe about three Feet high, but, unleſs the *Autumn* be very favourable, they ſeldom flower in this Country. The Root of this Plant is ſometimes us'd in Medicine.

The ſecond is preſerv'd by ſuch as are curious in collecting Exotick Plants. This may be propagated in the ſame manner as the former, as alſo from Seeds, which ſhould be ſown upon a Hot-bed in the *Spring*; and when the Plants come up, they may be treated in the manner directed for *Amaranths*; to which the Reader is deſir'd to turn, to avoid Repetition. Theſe Plants muſt be plac'd in the Stove in *Winter*, where they may have a moderate Degree of Warmth, and ſhould frequently be refreſh'd with Water. The ſecond Year they will produce Flowers in the *Autumn*, and if the Seaſon be warm, the Seeds will ripen. This Plant grows plentifully in *Jamaica*, and the *Caribee* Iſlands; and from the Name given to it by Dr. *Boerhaave*, it doth alſo grow in *Ceylon*.

The third Sort differs in nothing from the common Sort, which is mentioned above except in the Colour of the Flower; that having a purple, and this Sort a white Flower; ſo that they may be indifferently uſed in Medicine.

The fourth Sort was diſcovered by Dr. *Tournefort* in the *Levant*. This is a hardy Plant, which will endure the Cold of our ordinary Winters extremely well in the open Air. Both theſe Sorts may be propagated and managed in the ſame manner as directed above.

The fifth Sort was diſcovered by Father *Plumier*, in ſome of the *French* Settlements in *America*, and ſince was found by the late Dr. *Houſtoun* at *La Vera Cruz*. This Sort may be propagated by Seed, which ſhould be ſown on a Hot-bed early in the Spring, and muſt be afterward treated in the ſame manner as above directed for the ſecond Sort. This Sort will abide ſeveral Years, if it is preſerved in a Stove in the *Winter*, and will ripen Seed every Year.

PLUM TREE, *vide* Prunus.

PLUMERIA, The Jaſmine-tree, *vulgo*.

The *Characters* are;

It hath a funnel-ſhaped Flower, conſiſting of one Leaf, which is cut into ſeveral Segments at the Brim, out of whoſe Cup ariſes the Pointal, which afterward becomes the Fruit or Pod, which for the moſt part grow double, and open lengthwiſe, diſcovering the Seeds, which are oblong, and have a Border round them: theſe are ranged over each other like Slates on a Houſe, and are faſtened to the Placenta.

The *Species* are;

1. Plumeria *flore roſeo odoratiſſimo. Inſt. R. H.* Plumeria with a roſe-coloured ſweet-ſcented Flower, commonly called in the *Weſt-Indies* red Jaſmine.
2. Plumeria *flore majore odorato & incarnato.* Plumeria with a larger ſweet-ſcented and incarnate Flower, called in the *Weſt-Indies*, the Japan-tree.
3. Plumeria *flore niveo, foliis longis anguſtis & acuminatis. Inſt. R. H.* Plumeria with a ſnowy Flower, and long narrow pointed Leaves.
4. Plumeria *flore niveo, foliis brevioribus & obtuſis. Inſt. R. H.* Plumeria with a ſnowy Flower, and ſhorter blunt Leaves.
5. Plumeria *foliis longiſſimis, minus ſucculentibus, flore pallido. Houſt.* Plumeria with very long and leſs ſucculent Leaves, and a pale Flower.
6. Plumeria *folio latiore obtuſo, flore luteo minore.* Plumeria with a broad obtuſe Leaf, and a ſmaller yellow Flower.

This Name was given to this beautiful Genus of Plants, by Dr. *Tournefort*, in Honour to Father *Plumier*, who was Botaniſt to the late King of *France*, and a long Time in *America*, ſearching after new Plants, and who has publiſhed a Catalogue of the Plants he diſcovered, with the new Genus's he conſtituted: and two Volumes in Folio, with Figures and Deſcriptions of many of the Plants.

Theſe Plants grow wild in the *Spaniſh Weſt-Indies*, from whence ſome of the moſt beautiful Kinds were brought into the *Engliſh* Settlements in *America*, and are cultivated in their Gardens for Ornament. The firſt Sort here mentioned, is the moſt common Kind, which is preſerved in the Gardens of the Inhabitants of *Jamaica* and *Barbados*. The Flowers of this Kind nearly reſemble thoſe of the red Oleander, but are larger, and have an agreeable Odour. Theſe are produced in ſmall Bunches, at the Extremity of the Shoots, and generally appear in *July* and *Auguſt*, in this Climate; but in the *Weſt-Indies*, they flower a great Part of the Year.

The ſecond Sort I received from the Iſland of St. *Chriſtophers* by the Name of *Japan-tree*: this Sort is very rare in the *Engliſh* Settlements at preſent, having been but lately introduced from the *Spaniſh Weſt-Indies*: it is in Leaf and Stem very like the firſt, but the Flowers of this are of a paler Colour, and are produced in much larger Bunches. It is very common to have upward of twenty of theſe Flowers open in one Bunch, and a Number to ſucceed theſe as they decay, ſo as that the Bunches have continued in Beauty upward of two Months; during which time they make a moſt beautiful Appearance in the Stove, and have a very agreeable Flavour.

The third Sort grows plentifully at *Campechy*, from whence the late Dr. *Houſtoun* ſent the Seeds. He alſo obſerved ſome Plants of this Kind at *Jamaica*. The ſixth Sort is alſo pretty common in both thoſe Places. Theſe are not near ſo beautiful as the two former Sorts, their Flowers being ſmaller, and produced in leſſer Bunches, and are moreover of ſhorter Duration. But for the Beauty of their Stems and Leaves, and for the Sake of Variety, they deſerve Room in every curious Collection of Plants.

The fourth and fifth Sorts, were diſcovered by Dr. *Houſtoun*, growing in great plenty near *Carthagena* in the *Spaniſh Weſt-Indies*, from whence he ſent their Seeds to *England*. The fourth Sort produces ſmall white Flowers, reſembling thoſe of the third, ſo is leſs valuable than the two firſt. But the fifth Sort produces as large Flowers as the firſt; but they are of a pale red Colour, and ſmell very ſweet. The Leaves of this Sort are ſometimes ten Inches or a Foot in Length, and about three Inches over in their broadeſt Part. Theſe are not near ſo thick, or full of Juice, as are thoſe of the other Sorts, nor are they ſo deeply veined; but being of a bright ſhining green Colour, they make an agreeable Variety amongſt other tender exotick Plants in the Stove.

All theſe Plants may be propagated by Seeds, which ſhould be ſown in Pots filled with light rich Earth, and plunged into a Hot-bed of Tanners-bark; and when the Plants are come up about two Inches high, they ſhould be tranſplanted into ſeparate ſmall Pots, filled with light ſandy Earth, and plunged into the Hot-bed again, obſerving to ſhade them from the Heat of the Sun in the middle of the Day until they have taken Root: but they muſt not have much Water, for as all the Sorts are very ſucculent, being full of a milky Juice, ſomewhat like the Euphorbiums, ſo Moiſture will cauſe them to rot. In hot Weather the Plants ſhould have a pretty large ſhare of freſh Air admitted to them, by raiſing of the Glaſſes of the Hot-bed every Day, in proportion to the Warmth of the Seaſon. Toward *Michaelmas*, when the Nights begin to be cold, the Plants ſhould be removed into the Stove, and plunged into the Bark-bed, where they muſt remain during the *Winter*. As theſe Plants all caſt their Leaves in the Middle of *Winter*, and continue deſtitute of them till about the Beginning of *May*, ſo during that Time they ſhould be watered very ſparingly; becauſe they are in more danger of rotting, while they are in a leſs active State, by too much Moiſture, than when they are furniſhed with Leaves, thro' which the Moiſture is more freely perſpired.

All theſe Sorts are too tender to thrive in the open Air of this Country in the *Summer* Seaſon; ſo they ſhould be conſtantly preſerved in the Stove, where in warm Weather, they muſt have a large Share of free Air; but in cold Weather they muſt be kept very warm. While they are young, it will be proper to continue them in the Bark-bed, but when they have obtained Strength, they may be placed in the dry Stove, where they will thrive very well, provided they are kept in a moderate Temperature of Heat, and have not too much Water.

Theſe Plants may alſo be propagated by Cuttings, which ſhould be taken from the old Plants a Month before they are planted, during which Time they ſhould be laid on the Flues in the Stove, that the Part which joined to the old Plant, may be throughly healed, otherwiſe they will rot. Theſe Cuttings ſhould be planted in ſmall Pots filled with light ſandy Earth, and plunged into a moderate Hot-bed of Tanners-bark, obſerving to ſhade them juſt in the Heat of the Day from the Sun, and refreſh them every third or fourth Day with Water; but it muſt be given to them ſparingly each Time. If the Cuttings ſucceed they will have taken Root in about two Months, when they ſhould have a larger Share of Air, to harden them by Degrees to bear the Sun and Air, and afterward may be treated as the old Plants.

The milky Juice of theſe Plants is very cauſtic, and reckoned very poiſonous: in cutting off any of the Branches of the Plants, if the Knife be not immediately cleaned, the Juice will corrode it, and turn the Blade almoſt black in a very little Time, ſo as not to be cleaned off again; and if dropped on Linen, will cauſe it to waſh in Holes, equal to *Aquafortis*.

POINCIANA; Barbados Flower-Fence, *or* Spaniſh Carnations.

The *Characters* are;

The Flower conſiſts of ſeveral Leaves, which are plac'd in a circular Order; in the Centre of which ariſes a Number of crooked Stamina; the Pointal, which ariſes from a quinquifid Flower-cup, becomes a long, broad, flat Pod, opening into two Parts, and fill'd with broad, flat, roundiſh Seeds, each of which is lodg'd in a ſeparate Cell, which are divided by a thin Partition.

Poinciana *flore pulcherrimo. Tourn.* Barbados Flower-Fence, with a fair Flower.

This Plant is very common in the *Caribbee* Iſlands, where it is planted for a Fence to divide Fields, and is greatly eſteem'd for the Beauty of its Flowers, which are produc'd on long Spikes in vaſt Quantities. The Leaves of this Plant are alſo us'd inſtead of *Sena*, to purge withal.

This was carry'd from *Cape Verd* Iſlands to *Barbados*, as is related by *Ligon*, and hath ſince been diſperſed through the other Iſlands. It grows in thoſe Countries to be ten or twelve Feet high, and the Stem is often as large as the Small of a Man's Leg, and the Wood is very hard; from whence it hath obtain'd the Name of *Ebony* in ſome Places. There are ſome Varieties of this Tree in the *Weſt-Indies*, which differ in the Colour of their Flowers; but whether thoſe Variations do not ariſe from the ſame Seeds, I can't determine, ſince the Plant is ſo tender as to be rarely preſerv'd through the *Winter* in this Climate.

The Seeds of this Plant are annually brought over in Plenty from the *Weſt-Indies*, which, if ſown upon a Hot-bed, will riſe very eaſily: and when the Plants are come up, they ſhould be tranſplanted into ſmall Pots, and plung'd into a Hot-bed of Tanners-Bark, obſerving to ſhade them while they have taken Root; after which you muſt give them Air in Proportion to the Warmth of the Seaſon, and they muſt be frequently refreſh'd with Water. When the Plants have fill'd the Pots with their Roots, they ſhould be taken out, and plac'd into larger ones, that they may have Room to grow: If Care be taken to water and ſhift them as often as is neceſſary, they will grow to be three Feet high the firſt Seaſon. At *Michaelmas* the Pots ſhould be plung'd into a freſh Hot-bed of Tanners-Bark, in the Stove, which ſhould be kept to the *Anana*'s Heat, mark'd on Mr. *Fowler's Thermometers*, and frequently refreſh'd with Water, but you muſt never give them large Quantities, which is very injurious to theſe Plants at that Seaſon. The Earth which theſe Plants ſhould be planted in, muſt be freſh, light, and ſandy (but not over rich); in which they will ſtand the Winter better than if plac'd in a ſtronger Soil.

With this Management I have rais'd ſeveral Plants to be five Feet high; ſome of which I have preſerv'd two or three Years, and have had the Buds of the Flowers appear, but have not as yet been able to bring them to flower; tho' I am in hopes it may be effected, ſince the Improvements which are made every Year in the keeping of tender Plants, are very conſiderable.

To this *Article* muſt be added;

1. **Poinciana** *flore luteo. Houſt. Barbados* Flower-fence, with a yellow Flower.
2. **Poinciana** *flore rubente. Houſt.* Flower-fence with a reddiſh Flower.
3. **Poinciana** *ſpinoſa, vulgo.* TARA. *Feuil.* Prickly Flower-fence, commonly called *Tara*.

The firſt and ſecond Sorts were diſcovered by the late Dr. *Houſtoun* at *Campechy*, where they grew in great Plenty. Theſe do not differ in any thing from the common Sort, before mentioned, except in the Colour of their Flowers; that having a Flower variegated with Red and Yellow, and theſe have Flowers one of them intirely Yellow, and the other of a plain red Colour.

The third Sort was diſcovered by *Pere Feuillée*, growing plentifully in the Vallies of *Lima*. The Flowers of this Kind are ſmaller than thoſe of the other Sorts, and are of a greeniſh yellow Colour, ſo that they are not near ſo beautiful. The Seed-pods of this Sort are uſed by the Dyers in the *Spaniſh Weſt-Indies*, for Dying of Black; and they are alſo uſed for making of Ink: the Infuſion of theſe Pods with Galls, affords the moſt beautiful black Ink in the World.

Theſe three Sorts may be propagated by Seeds, which ſhould be ſown on a Hot-bed early in the Spring; and when the Plants come up, they muſt be treated in the ſame manner as is directed for the common Sort, in the former part of this Article.

POKE VIRGINIAN, *vide* Phytolacca.

POLEMONIUM; [This Plant is ſo call'd of πολὺ *much* and *μόνον alone*, becauſe there are many of its Lobes go to the making of one Leaf. It is alſo call'd *Greek Valerian*, becauſe it was brought from *Greece*.] Greek Valerian, *or* Jacob's Ladder.

The *Characters* are;

The Flower conſiſts of one Leaf, which is divided deeply into five Parts, and is Wheel-ſhap'd; the Pointal which riſes from the Flower-cup, afterwards becomes a roundiſh Fruit, divided into three Cells, which are fill'd with oblong Seeds; to which ſhould be added, The Leaves are pinnated.

The *Species* are;

1. **Polemonium** *vulgare cœruleum. Tourn.* Greek Valerian, with a blue Flower.
2. **Polemonium** *vulgare album. Tourn.* Greek Valerian, with a white Flower.
3. **Polemonium** *vulgare, flore variegato. Tourn.* Gree Valerian, with a ſtrip'd Flower.
4. **Polemonium** *vulgare, foliis eleganter variegati Boerh. Ind.* Greek Valerian, with beautiful ſtrip'd Leave

The two firſt *Species* are very common in many *Engli* Gardens, where they are cultivated for the Beauty of th Flowers: They have alſo been found wild in *Carleton Be* and about *Malham Cove* near *Craven*. The Sort with variegated Flowers, as alſo that with ſtriped Leaves, are Varieti which have been obtained from the former.

Theſe Plants are eaſily propagated, by ſowing their Seed in the *Spring* upon a Bed of light Earth; and when they ar come up pretty ſtrong, they ſhould be pricked out into another Bed of the ſame light Earth, about three Inches aſunder, obſerving to ſhade and water them until they have taken Root, after which they will require no farther Care bu to keep them clear from Weeds, until *Michaelmas*; at whic Time they muſt be tranſplanted into the Borders of th Flower Garden, where, being intermixed with different Sor of Flowers, they will make a beautiful Appearance. The produce their Flowers in *May* and *June*, and their Seeds ripe in *Auguſt*.

The variegated Kinds are preſerved by parting of thei Roots, becauſe the Plants raiſed from Seeds would be ſubject to degenerate, and become plain. The beſt Time t part them is about *Michaelmas*, that they may take goo Root before the cold Weather prevents them. Theſe ſhou have a freſh light Soil, but if it be too rich, their Roots wi rot in *Winter*, and their Stripes will go off.

POLIUM; [This Plant is ſo called of πολιὸς, *hoary*, much as to ſay, the *hoary Herb*, becauſe it was the whi *Poley* of the Ancients] Poley-mountain.

The *Characters* are;

It hath a labiated Flower, conſiſting of one Leaf, whoſe Stmina ſupply the Place of the Creſt; the Beard (or Under-lip) divided into five Segments, as the Germander; out of t Flower-cup riſes the Pointal, attended, as it were, by f Embryo's, which afterwards become ſo many Seeds, ſhut up the Flower-cup: To theſe marks muſt be added, That the Flo ers are collected into a Head upon the Tops of the Stalks a Branches.

The *Species* are;

1. **Polium** *montanum luteum. C. B. P.* Yellow Mou tain-poley.

2. Poli

2. **Polium** *montanum album. C. B. P.* White Poley-mountain.

3. **Polium** *lavendulæ folio. C. B. P.* Poley-mountain, with a Lavender Leaf.

4. **Polium** *lavendulæ folio anguſtiori. C. B. P.* Poley-mountain, with a narrower Lavender Leaf.

5. **Polium** *Pyreniacum ſupinum, hederæ terreſtris folio. Tourn.* Creeping *Pyrenian* Poley-mountain, with a Ground-ivy Leaf.

6. **Polium** *maritimum erectum Monſpeliacum. C. B. P.* Upright Poley-mountain of *Montpelier*.

7. **Polium** *montanum luteum, ſerratis anguſtioribus incanis foliis. Barrel.* Yellow Poley-mountain, with narrow hoary ſerrated Leaves.

There are ſeveral other *Species* of this Plant, which are preſerved in ſome curious Botanick Gardens for Variety; but thoſe here mentioned, are what I have obſerved in the *Engliſh* Gardens.

Theſe Plants are all propagated by planting their Cuttings in a Bed of light freſh Earth, during any of the *Summer* Months, which ſhould be watered and ſhaded until they have taken Root; after which they will require no other Culture than to keep them clear from Weeds until *Michaelmas*; when they ſhould be tranſplanted into a warm Situation, and muſt have a very dry Soil, otherwiſe they are ſubject to decay in *Winter*, for they are Natives of warm Countries; but if they are placed in a dry Rubbiſh, under the Shelter of a Wall or Pale, they will endure the Cold of our ordinary *Winters* very well. Theſe Plants produce their Flowers in *June* and *July*, but do rarely perfect their Seeds in this Country. Their Flowers have very little Beauty in them, but for their hoary Leaves, and odd Appearance, a few Plants of them may be admitted for Variety. The ſecond Sort is uſed in Medicine.

To this *Article* muſt be added;

1. **Polium** *montanum alterum, foliis anguſtioribus, capitulis longioribus. C. B. P.* Another Mountain-poley, with narrower Leaves, and longer Heads.

2. **Polium** *montanum repens. C. B. P.* Creeping Poley-mountain.

3. **Polium** *maritimum ſupinum Venetum. C. B. P.* Creeping maritime *Venetian* Poley-mountain.

4. **Polium** *Hiſpanicum, Chamædryos folio, purpuraſcente flore. Inſt. R. H. Spaniſh* Poley-mountain, with a germander Leaf, and a purpliſh Flower.

5. **Polium** *Luſitanicum ſupinum minus incanum, caulibus purpuraſcentibus, flore albo. Inſt. R. H.* Creeping leſs hoary *Portugal* Poley-mountain, with purpliſh Stalks, and a white Flower.

6. **Polium** *Hiſpanicum latifolium, capitulo breviori, purpuraſcente flore. Inſt. R. H.* Broad-leafed *Spaniſh* Poley-mountain, with a ſhorter Head, and purpliſh Flower.

7. **Polium** *Hiſpanicum maximum album. Inſt. R. H.* The largeſt white *Spaniſh* Poley-mountain.

8. **Polium** *Hiſpanicum maximum luteum. Inſt. R. H.* The greateſt yellow *Spaniſh* Poley-mountain.

9. **Polium** *Hiſpanicum maritimum fruteſcens, roriſmarini folio, flore rubro. Inſt. R. H.* Shrubby maritime *Spaniſh* Poley-mountain, with a Roſemary Leaf, and a red Flower.

10. **Polium** *Hiſpanicum ſupinum, flore flaveſcente. Inſt. R. H.* Creeping *Spaniſh* Poley-mountain, with a yellowiſh Flower.

11. **Polium** *Hiſpanicum, linariæ foliis brevioribus, flore albo. Inſt. R. H. Spaniſh* Poley-mountain, with ſhorter Toadflax Leaves, and a white Flower.

12. **Polium** *montanum gnaphaloides inciſum, flore rubro, & ſupinum. Barr. Icon.* Creeping Poley-mountain, reſembling Cudweed, with a red Flower.

13. **Polium** *Hiſpanicum luteum, majoranæ folio. Inſt. R. H.* Yellow *Spaniſh* Poley-mountain, with a Marjoram Leaf.

14. **Polium** *Hiſpanicum, ſerpylli folio, purpuraſcente flore. Inſt. R. H. Spaniſh* Poley-mountain, with a Mother-of-thyme Leaf, and a purpliſh Flower.

15. **Polium** *Hiſpanicum, thymi folio, purpuraſcente coma. Inſt. R. H. Spaniſh* Poley-mountain, with a Thyme Leaf, and a purpliſh Top.

16. **Polium** *Creticum maritimum humifuſum. Tourn. Cor.* Trailing maritime Poley-mountain of *Crete*.

17. **Polium** *Smyrnæum, ſcordii folio. Tourn. Cor. Smyrna* Poley-mountain, with a Water-germander Leaf.

All theſe Sorts of Poley-mountain are pretty hardy Plants, ſo will endure the Cold of our ordinary *Winters* in the open Air, provided they are planted in a warm Situation, and on a dry ſtony Soil; for if they are planted in a rich moiſt Soil, they will grow very freely in *Summer*; but being replete with Juice are apt to rot in *Winter*; ſo that when they are planted on a lean ſtony Soil, where they will be ſtunted and grow ſhort, and have ſmall Leaves, they will abide ſeveral Years. Theſe Plants ſeldom produce good Seeds in this Country, ſo are propagated by Cuttings, which may be planted any time in the *Summer*, in a Bed of freſh Earth, obſerving to ſhade them until they have taken Root, as alſo to refreſh them with Water in dry Weather. When they are rooted, they will want no farther Care, but to keep them clear from Weeds; and at *Michaelmas* they may be tranſplanted into the Places where they are deſigned to remain, that they may be well rooted before the Froſt comes on.

Theſe Plants are chiefly preſerved in Botanic Gardens for Variety; but they may be rendered ornamental in other Gardens, where they will grow on ſtony gravelly Soils; and their hoary Leaves and Branches, with the different Colour of their Flowers, will make an agreeable Proſpect, if they are properly diſpoſed.

POLYANTHOS, *vide* Primula Veris.

POLYGALA: This Plant is ſo called of πολὺ, *much*, and γαλα, *Milk*, becauſe if Cattle are fed in Marſhes that produce this Plant, they give a great Quantity of Milk: It is alſo called *Ambervalis*, of *Ambiendis Arvis*, from luſtrating the Fields, becauſe the Ancients uſed to crown Virgins with the Flowers of this Plant, when they perambulated the Fields, to implore Fertility thereto: It is alſo called *Amarella*, becauſe it has a bitter Taſte] Milkwort.

The *Characters* are;

It hath a Flower conſiſting of one Leaf, of an anomalous Figure, perforated behind, but divided into two Lips before; the uppermoſt Lip is divided into two Parts, but the under one is curiouſly fringed; out of the lower Part of the Flower riſes the Pointal, which afterwards becomes a broad Fruit, divided into two Cells, which contain oblong Seeds; the Fruit is generally incloſed in the Flower-cup, which is compoſed of five Leaves, viz. three ſmall ones, and two larger, which afterwards embrace the Fruit like Wings,

The *Species* are;

1. **Polygala** *major cærulea. Tabern.* Greater blue Milkwort.

2. **Polygala** *major alba. Tabern.* Greater white Milkwort.

3. **Polygala** *vulgaris. C. B. P.* Common Milkwort, with a blue Flower.

4. **Polygala** *alba. Tabern.* White common Milkwort.

5. **Polygala** *Africana fruteſcens, folio buxi, flore maximo. Oldenl.* Shrubby *African* Milkwort, with a Box Leaf, and a very large Flower.

6. **Polygala** *acutioribus foliis, Monſpeliaca. C. B. P. Montpelier* Milkwort, with ſharp-pointed Leaves.

7. **Polygala** *acutioribus foliis, Monſpeliaca floribus cæruleis. H. R. Monſ. Montpelier* Milkwort, with ſharp-pointed Leaves, and blue Flowers.

8. **Polygala** *foliis lanceolatis brevibus. Bocc. Muſ.* Milkwort, with ſhort ſpear-ſhaped Leaves.

9. **Polygala** *montana minima myrtifolia. Inſt. R. H.* The leaſt Mountain-milkwort, with a Myrtle Leaf.

10. **Polygala** *Cretica vulgari ſimilis, flore albido longiore. Tourn. Cor.* Milkwort of *Crete* like the common Sort, with a longer whitiſh Flower.

11. **Polygala** *Orientalis ſupina myrtifolia, flore cæruleo. Tourn. Cor.* Low *Eaſtern* Milkwort, with a Myrtle Leaf, and a blue Flower.

12. **Polygala** *Orientalis linifolia, flore magno albo. Tourn. Cor. Eaſtern* Milkwort, with a flax Leaf, and a large white Flower.

13. **Polygala** *Orientalis linifolia, flore magno purpureo. Tourn. Cor. Eaſtern* Milkwort, with a flax Leaf, and a large purple Flower.

14. **Polygala** *Luſitanica fruteſcens, magno flore, foliis minimis. Inſt. R. H.* Shrubby *Portugal* Milkwort, with a large Flower, and very ſmall Leaves.

15. **Polygala** *Africana fruteſcens anguſtifolia major. Oldenl.* Greater ſhrubby *African* Milkwort, with a narrow Leaf.

16. **Polygala** *Africana, lini folio, magno flore. Oldenl. African* Milkwort, with a Flax Leaf, and a large Flower.

17. **Polygala** *Virginiana, foliis oblongis, floribus in thyrſo candidis, radice alexipharmica.* Milkwort of *Virginia*, with oblong Leaves, and white Flowers, growing in a looſe Spike,

whoſe Root is alexipharmic, commonly called the *Senegaw Rattle-ſnake-root.*

18. Polygala *cœrulea Americana, anguſtis & denſioribus foliis, vulgo Clin-clin. Feuillée.* Blue *American* Milkwort, with narrow Leaves, commonly called by the *Indians*, *Clin-clin.*

19. Polygala *rubra Virginiana, ſpicâ parvâ compactâ. Baniſt.* Red *Virginian* Milkwort, with a ſmall compact Spike.

20. Polygala *ſpicata rubra major, foliis & caulibus cœruleſcentibus. Baniſt.* Greater red ſpiked Milkwort, with bluiſh Leaves and Stalks.

21. Polygala *ſ. Flos Ambarvalis Virginiana, floribus luteis in caput oblongum congeſtis. Baniſt. Virginian* Milkwort, with yellow Flowers, collected in an oblong Head.

22. Polygala *quadrifolia ſ. cruciata, floribus ex viridi rubentibus, in globam compactis. Baniſt.* Four-leafed Milkwort, with reddiſh green Flowers, growing in a compact Globe.

23. Polygala *quadrifolia minor Virginiana, ſpicâ parvâ rubenti. Baniſt.* Smaller four-leafed *Virginian* Milkwort, with a ſmall reddiſh Spike.

24. Polygala *Mariana, anguſtiore folio, flore purpureo. Pluk. Mantiſ.* Narrow-leafed Milkwort of *Maryland*, with a purple Flower.

25. Polygala *Mariana quadrifolia minor, ſpicâ parvâ albicante. Pluk. Mantiſ.* Smaller four-leafed Milkwort of *Maryland*, with a ſmall whitiſh Spike.

The four firſt *Species* are found wild in moiſt Meadows in divers Parts of *England*, and are never preſerved in Gardens, except for the ſake of Variety: However, I thought proper to inſert them in this Place, to introduce the fifth Sort, which is a beautiful Plant, and is worthy to be preſerved in all curious Collections of rare Plants.

This is propagated by Seeds, which ſhould be ſown upon a moderate Hot-bed in the *Spring*; and when the Plants are come up, they ſhould be pricked into ſmall Pots, filled with light rich Earth, and plunged into another Hot-bed, where they ſhould be ſhaded until they have taken Root, and often refreſhed with Water; after which they muſt have Air given them, in Proportion to the Warmth of the Seaſon, and in *July* they may be removed into the open Air, placing them in a warm Situation, where they may be ſheltered from ſtrong Winds, and in dry Weather they muſt be often refreſhed with Water: In this Place they may remain until *October*, when the Nights begin to be froſty; then you ſhould remove them into the Green-houſe, placing them where they may have the Advantage of the free Air, when the Weather is favourable enough to admit of the Glaſſes being opened, for they only require to be protected from Froſt: During the *Winter* Seaſon they ſhould often be refreſhed with Water, but it ſhould not be given to them in large Quantities, which will injure their Roots: In *Summer* they may be expoſed with *Myrtles*, *Geraniums*, &c. in a Situation where they are defended from ſtrong Winds; and as their Roots increaſe, ſo the Size of their Pots ſhould be enlarged; but you muſt be very cautious not to over-pot them, which is injurious to all Sorts of *Exotick* Plants.

The Earth in which theſe Plants are ſet ſhould be rich, freſh and light, in which they will thrive exceedingly, and continue in Flower moſt part of the Year, which renders it very valuable, and if the Seaſon proves favourable, the Seeds will ripen very well; but you muſt be careful to gather them when ripe, otherwiſe they will drop off and be loſt.

The ſixth, ſeventh, eighth and ninth Sorts are low Plants, which grow in *Spain*, *Italy*, and the South of *France*; as are alſo the tenth, eleventh, twelfth and thirteenth Sorts, which were diſcovered by Dr. *Tournefort* in the *Levant*. Theſe are hardy Plants, which will live in the open Air in this Country, and may be propagated by Seeds, in the ſame manner as the common Sort.

The fourteenth and fifteenth Sorts are ſhrubby Plants, which are preſerved in ſome curious Gardens for Variety. Theſe may be alſo propagated by Seeds, which ſhould be ſown on a moderate Hot-bed in the *Spring*; and when the Plants are come up, they ſhould be tranſplanted into ſeparate Pots, filled with light freſh Earth, and then plunged into the Hot-bed again, obſerving to ſhade them from the Sun until they have taken Root; after which Time they ſhould have a large Share of freſh Air in warm Weather, and muſt be frequently watered. About the Middle of *May* theſe Plants ſhould be inured to bear the open Air by Degrees, and in *June* they may be placed abroad in a ſheltered Situation, where they may remain during the *Summer* Seaſon; and in *Autumn* they muſt be removed into the Green-houſe, and managed as hath been directed for the fifth Sort. Theſe Plants continue a long time in Flower, ſo are worthy of a Place in every curious Garden, for the ſake of Variety.

The ſixteenth Sort is a native of the *Cape of Good Hope*, and the eighteenth grows on the Mountains in the Kingdom of *Chily* in the *Spaniſh Weſt-Indies*, where it is uſed by the *Indians*, to cure Pleuriſies, and all Complaints of the Side. Theſe two Sorts are of low Growth, ſeldom riſing higher than the common Sort; but are too tender to live in the open Air in *England*; ſo they ſhould be planted in Pots, and preſerved in the Green-houſe in *Winter*. Theſe may be propagated by Seeds, as the two former Sorts.

The other Sorts are all of them Natives of *Virginia*, *Maryland*, *New-England*, and ſeveral other Places in the North of *America*, ſo are hardy enough to live in the open Air in *England*, provided they are planted in a warm Situation, and on a light Soil. Theſe are very pretty Plants, and require very little Trouble to cultivate them; for after they are come up from Seeds, the only Care they require is to keep them clear from Weeds, and in very dry Weather to water them while they are young; for when they have obtained Strength, they will not be in much Danger of ſuffering by Drought; for the Roots run pretty deep into the Ground, ſo will find Nouriſhment to ſupport them.

The Root of the ſeventeenth Sort hath been long uſed by the *Senegaw Indians* to cure the Bite of the Rattle-ſnake, which, if taken in Time, is an infallible Remedy. And of late Years it hath been uſed by the Inhabitants of *Virginia* in many Diſorders, which are occaſioned by a thick fizy Blood; ſo that the Root of this Plant, when its Virtues are fully known, may become one of the moſt uſeful Medicines yet diſcovered. The eighteenth Sort, by the Account which *Pere Feuillée* gives of it, partakes of the ſame Qualities with this, though the *Indians* uſe it differently; for he ſays they make a Decoction of the Plant, which they drink to cure the Pain of the Side; whereas the *Senegaw Indians* uſe the Root of the ſeventeenth Sort, which they powder and generally carry about them when they travel in the Woods, leſt they ſhould be bit by the Rattle-ſnake; and whenever this happens, they take a Quantity of the Powder inwardly, and apply ſome of it to the Part bitten, which is a ſure Remedy.

POLYGONATUM; [ſo call'd of πολὺ *many*, and γόνυ a *Knee*, becauſe it has many little Knees, for the Root is very knotty: It is alſo call'd *Solomon's-Seal*, becauſe the Knots of the Root ſomewhat reſemble a Seal] Solomon's-Seal.

The *Characters* are;

The Flower conſiſts of one Leaf, is tuberoſe, and expands at the Top in Shape of a Bell, and is divided into ſeveral Segments; the Ovary, which is ſituated in the Centre of the Flower, becomes a ſoft globular Fruit, containing roundiſh Seeds.

The *Species* are;

1. Polygonatum *latifolium vulgare. C. B. P.* Common Broad-leav'd Solomon's-Seal.

2. Polygonatum *latifolium vulgare, caulibus rubentibus. H. L.* Common broad-leav'd Solomon's Seal, with red Stalks.

3. Polygonatum *latifolium minus, flore majore. C. B. P.* Leſſer broad-leav'd Solomon's-Seal, with a larger Flower.

4. Polygonatum *latifolium, flore duplici odoro. H. R. Par.* Broad-leav'd Solomon's Seal, with a double ſweet-ſmelling Flower.

5. Polygonatum *latifolium maximum. C. B. P.* The greateſt broad-leaved Solomon's-Seal.

6. Polygonatum *latifolium, helleberi albi foliis. C. B. P.* Broad-leaved Solomon's-Seal, with Leaves like the white Hellebore.

7. Polygonatum *latifolium, flore majore odoro. C. B. P.* Broad-leaved Solomon's-Seal, with a large ſwee Flower.

8. Polygonatum *Orientale latifolium, flore parvo. Tourn. Cor.* Eaſtern broad-leav'd Solomon's-Seal, with ſmall Flower.

9. Polygonatum *anguſtifolium non ramoſum. C. B. P.* Narrow-leaved unbranched Solomon's-Seal.

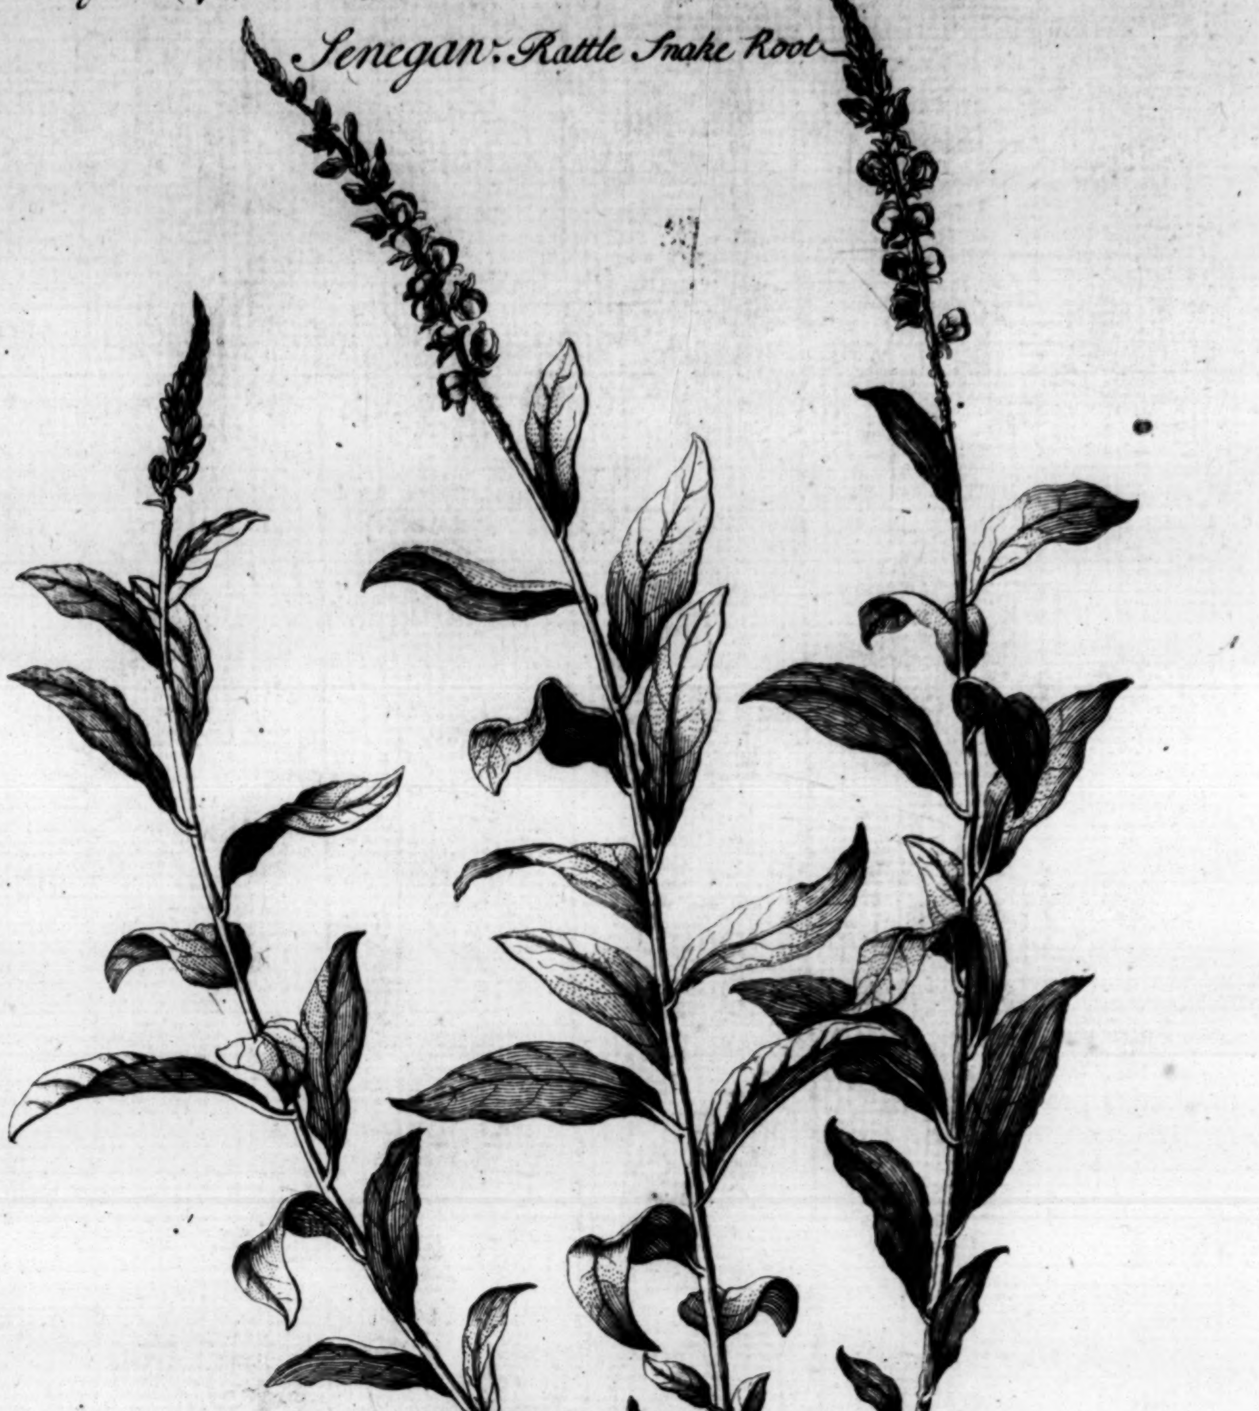
10. Polygonatum *anguſtifolium ramoſum. C. B. P.* Narrow-leaved branching Solomon's-Seal.

11. Polygonatum *Americanum ſcandens altiſſimum, foliis tamni. Plum.* The talleſt climbing *American* Solomon's-Seal.

Th

POLYGALA, *Virginiana foliis oblongis floribus in thyrso candidis radice Alexipharmica*

Senegan: Rattle Snake Root



place this at polygala

The firſt four mention'd are the principal Sorts cultivated in *England*.

Theſe Plants are eaſily propagated by parting of their Roots in the *Spring* before they begin to Shoot, obſerving always to preſerve a Bud to each Off-ſet: They ſhould be planted in a freſh light Earth, where they will thrive exceedingly; but if it be over rich, it will deſtroy their Roots. The firſt Sort is the moſt common in *England*, and is what the College has directed for Medicinal Uſe.

The fifth and ſixth Sorts grow very tall, provided they are planted in a pretty good Soil. In a moiſt Seaſon it is common for theſe to be upward of three Feet high, whereas the ordinary Sort ſeldom riſes above half that Height. The Leaves of theſe Sorts are alſo very large, ſo that they make a handſome Appearance in the Borders of large Gardens.

The ſeventh Sort hath broader Leaves than the common Sort, but doth not grow much higher. The Flowers of this Sort, being larger, and having an agreeable Scent, render it worthy of a Place in large Gardens.

The eighth Sort was diſcovered by Dr. *Tournefort* in the *Levant*, but is not common in *Europe*: this hath a broader Leaf than the common Sort, and the Flower is much ſmaller. It is preſerved in ſome curious Botanic Gardens, for the ſake of Variety.

The ninth and tenth Sorts are very different from either of the former: theſe have four or five Leaves, produced at each Joint, which are much longer and narrower than thoſe of the common Sort, ſo that they make a very different Appearance; therefore ſhould be allowed a Place in large Gardens for the ſake of Variety.

All theſe Sorts are as hardy as the common Solomon's-Seal, and may be propagated by parting of their Roots, in the ſame manner as directed for the common Sort.

The eleventh Sort is a Native of the warmeſt Parts of *America*, where it grows in the Woods, and climbs on whatever Trees grow near it, by the Help of which it riſes to a great Height. This produces its Flowers in long Bunches, ſomewhat like the black Briony. The Seeds of this Plant were ſent from *Campechy*, by Mr. *Robert Millar* Surgeon. This Plant muſt be preſerved in Stoves, otherwiſe it will not live thro' the Winter in this Country; it may be propagated by Seeds, which ſhould be ſown on a Hot-bed early in the Spring; and when the Plants are come up, they ſhould be treated in the ſame manner as hath been directed for *Dioſcorea*: with which Management this Plant will thrive, and produce Flowers in this Country.

POLYPODIUM; of [πολύς *many*, and ποῦς a *Foot*, q. d. *many Feet*. This kind of Plant ſtrikes its Roots into every Part that it can lay hold of, whether it be Stone, Earth, or Tree, it is the ſame thing, eſpecially if it be a Tree of the Oak Kind] Polypody.

The *Characters* are;

It is a Capillary Plant, with oblong jagged Leaves, having a middle Rib, which joins them to the Stalks running through each Diviſion.

The *Species* are;

1. Polypodium *vulgare. C. B. P.* Common *Polypody.*
2. Polypodium *majus, ſerrato folio. Barr. Icon.* Greater *Polypody*, with a ſerrated Leaf.
3. Polypodium *Cambro-Britannicum, pinnulis ad margines laciniatis. Raii Syn.* Welſh *Polypody*, with laciniated Leaves.

There are ſeveral other *Species* of this Plant, which are preſerv'd in ſome curious *Botanick* Gardens for Variety; but as they are rarely cultivated in other Gardens, ſo it is not worth while to enumerate them in this Place.

The firſt Sort is that which is us'd in Medicine, and is found growing upon old Walls and ſhady Banks in divers Parts of *England*. The ſecond ſeems to be only a Variety of the firſt, which differs therefrom in being larger, and having ſerrated Leaves. The third Sort was brought from *Wales*, where it grows in great Plenty, and is the moſt beautiful of all the Sorts. Theſe Plants may be propagated by parting of their Roots in the *Spring* before they ſhoot, and ſhould be planted in a very poor moiſt Soil under the Shade of a Wall, for if they are expos'd to the Sun, they will not thrive: They chiefly delight to grow out of the Joints of Walls, and old Buildings, but are commonly found expos'd to the North.

POMEGRANATE, *vide* Punica.

POMUM ADAMI, *vide* Aurantium.

POPULAGO: [This Plant is ſo call'd, of *Populus* the *Poplar-Tree*, becauſe it grows near Banks and Ditches under the *Poplar-Tree*] Marſh Marygold.

The *Characters* are;

The Flower conſiſts of ſeveral Leaves, which are plac'd circularly, and expand in Form of a Roſe, *in the Middle of which riſes the Pointal, which afterwards becomes a membranaceous Fruit, in which there are ſeveral Cells (which are for the moſt part bent downwards) collected into little Heads, and are full of oblong Seeds.*

The *Species* are;

1. Populago *flore majore. Tourn.* Marſh Marygold, with a larger Flower.
2. Populago *flore minore. Tourn.* Marſh Marygold, with a ſmaller Flower.
3. Populago *flore pleno. Tourn.* Marſh Marygold with a double Flower.

The two firſt Sorts are very common on boggy and watry Places in divers Parts of *England*, and are ſeldom cultivated in Gardens: But the third Sort, which is a Variety from the ſecond, is preſerv'd in Gardens for its fine double Flowers.

This Plant is propagated by parting of the Roots in *Autumn*, and muſt be planted on a moiſt Soil, otherwiſe the Flowers will not be near ſo fair, nor will the Plants thrive. Theſe are very proper to place in very wet Parts of the Garden, where few other Plants will thrive, and will afford an agreeable Variety during their Seaſon of Flowering, which is from the Middle of *April* until the Latter-end of *May*; ſo that they are worthy of a Place in every curious Flower-Garden.

POPULUS; the Poplar-Tree.

The *Characters* are;

The Leaves are broad, and for the moſt part angular; the Male Trees produce amentaceous Flowers, which have many little Leaves and Apices, but are barren: The Female Trees produce membranaceous Pods, which open into two Parts, containing many Seeds, which have a large Quantity of Down adhering to them, and are collected into Spikes.

The *Species* are;

1. Populus *alba, minoribus foliis. C. B. P.* White *Poplar*, with ſmaller Leaves.
2. Populus *alba, majoribus foliis. C. B. P.* White *Poplar*, with large Leaves, *commonly call'd* The Abele Tree.
3. Populus *tremula. C. B. P.* The Trembling *Poplar* or Aſpen-Tree.
4. Populus *nigra. C. B. P.* The Black *Poplar-Tree*, *by ſome falſly call'd* The Cotton-Tree.
5. Populus *alba, folio minore variegato.* The white *Poplar*, with ſtrip'd Leaves.
6. Populus *nigra Caroliniana, folio maximo, gemmis balſamum odoratiſſimum fundentibus. Cateſb.* The *Carolina* black Poplar, with the largeſt Leaf, from whoſe Buds iſſue a very ſweet Balſam.

Theſe Trees may be propagated either from Layers or Cuttings, which will readily take Root, as alſo from Suckers, which the White *Poplars* ſend up from their Roots in great Plenty. The beſt Time for tranſplanting theſe Suckers, is in *October*, when their Leaves begin to decay. Theſe may be plac'd in a Nurſery for two or three Years, to get Strength, before they are planted out where they are deſign'd to remain: But if you intend to propagate them from Cuttings, it is better to defer the doing of that until *February*; at which time you may Plant Truncheons of four or five Feet long, thruſting them about a Foot into the Ground: Theſe will readily take Root, and if the Soil be moiſt in which they are planted, will arrive to a conſiderable Bulk in a few Years.

The black *Poplar* is not ſo apt to take Root from large Truncheons, therefore 'tis the better Method, to plant Cuttings about a Foot and a half in Length, thruſting them a Foot deep into the Ground: Theſe will take Root very freely, and may be afterwards tranſplanted where they are to remain. This Sort will grow upon almoſt any Soil, but will thrive beſt in moiſt Places.

I have planted Cuttings of this Tree, which in four Years, have been bigger in the Trunk than a Man's Thigh, and near twenty Feet in Height, and this upon a very indifferent Soil; but in a moiſt Soil, it is common for theſe Trees to ſhoot twelve or fourteen Feet in a Seaſon: So that where a Perſon hath a mind to make a Shelter in a few Years, there is ſcarce any Tree ſo proper for that Purpoſe as this: But they ſhould not be planted too near the Pleaſure-garden, becauſe the Down which falls from theſe Trees will make a prodigious Litter.

The White Sorts, as alſo the *Aſpen-Tree*, do alſo cauſe a great Litter in the *Spring*, when their Down falls off; and their Roots being very apt to produce a large Quantity of Suckers, renders them unfit to be planted near an Houſe or Garden; but when they are interſpers'd with other Trees in large Plantations, they afford an agreeable Variety; their Leaves being very white on their Underſides, which when blown with the Wind, are turn'd to Sight.

A conſiderable Advantage may be obtain'd by planting theſe Trees upon moiſt boggy Soils, where few other Trees will thrive: Many ſuch Places there are in *England*, which do not, at preſent, bring in much Money to their Owners; whereas if they were planted with theſe Trees, they would, in a very few Years, over-purchaſe the Ground, clear of all Expence: But there are many Perſons in *England*, who think nothing, except Corn, worth cultivating: or, if they plant Timber, it muſt be *Oak*, *Aſh*, or *Elm*; and if their Land be not proper for either of theſe, it is deem'd little worth; whereas if the Nature of the Soils was examin'd, and proper Sorts of Plants adapted to them, there might be very great Advantage made of ſeveral large Parcels of Land, which at this time lie neglected.

The wood of theſe Trees, eſpecially of the *Abele* is very good to lay for Floors, where it will laſt many Years; and for its exceeding Whiteneſs, is, by many Perſons, preferr'd to *Oak*; but being of a ſoft Contexture, is very ſubject to take the Impreſſion of Nails, *&c.* which renders it leſs proper for this Purpoſe: it is alſo very proper for Wainſcoting of Rooms, being leſs ſubject to ſwell or ſhrink than moſt other Sorts of Wood: But for Turnery Ware, there is no Wood equal to this for its exceeding Whiteneſs, ſo that *Trays*, *Bowls*, and many other Utenſils are made of it; and the Bellows-makers prefer it for their Uſe; as do alſo the Shoemakers, not only for Heels, but alſo for the Soles of Shoes: It is alſo very good to make light Carts; and the Poles are very proper to ſupport *Vines*, *Hops*, &c. and the Lopping will afford good Fuel, which in many Countries is much wanted.

The ſixth Sort of Poplar-tree grows by the Sides of Rivers, and in other moiſt Places, in *South Carolina*, where it riſes to be a very large Tree. The young Branches of this Tree are commonly angular, ſometimes having three, and at other times four Angles. The Leaves are much broader, and are not ſo pointed, as thoſe of the common black Poplar. The Buds of the Leaves are very large, and in the Spring, juſt before they puſh, there iſſues out of them a very ſweet Balſam.

Altho' this Tree is a Native of a much warmer Country than *England*, yet it is hardy enough to endure the Cold of our Winters in the open Air; and may be propagated by Cuttings, in the ſame manner as the common black Poplar: the beſt Time to Plant theſe Cuttings, is in the Beginning of *March*. Theſe Cuttings ſhould be about a Foot or fourteen Inches long, and ſhould be planted ſix or eight Inches in the Ground. If the Spring ſhould prove dry, they muſt be frequently watered until they have made Roots; after which Time they will require no farther Care, but to keep them clear from Weeds. Theſe Cuttings will be rooted enough to bear tranſplanting in one Year; ſo the *March* following they ſhould be removed, and planted either in a Nurſery, where they may be trained up to Stems, or in the Places where they are deſigned to remain, which muſt be in a moiſt Soil, where they will grow to be large Trees; and being intermixed with other Trees of the ſame Growth, will make an agreeable Diverſity.

PORRUM [in *Greek* is call'd πράσον of πράω to *enkindle*, as though a Plant that excites a Warmth in the Body] Leek.

The *Characters* are;

The Flower conſiſts of ſix Petals, and is ſhap'd, as it were, like a Bell; in the Centre ariſes the Pointal, which afterwards becomes a roundiſh Fruit, divided into three Cells, which contain roundiſh Seeds: To theſe Notes muſt be added, The Stamina *are generally broad, and flat, ending in three Capillaments; of which the middle one is furniſh'd with a Chive; the Flowers are alſo gather'd into almoſt globular Bunches; the Roots are long, cylindrical, and coated; the Coats ending in plain Leaves.*

The *Species* are;

1. PORRUM *commune capitatum. C. B. P.* The common Leek.

2. PORRUM *ſectivum latifolium. C. B. P.* Broad-leav'd Leek, *commonly call'd* The London Leek.

There are ſome other *Species* of this Plant, which grow wild in the South of *France* and *Spain*, but as they are ſeldom cultivated in Gardens, ſo I ſhall forbear to mention them here. The two Sorts here mention'd, are by many Perſons affirm'd to be ſame, both of them riſing from the ſame Seed; but this is what the Gardeners near *London* will not believe, for they never ſow the Seeds of the latter, if they can procure thoſe of the firſt Sort, there being a great Difference in the Size of the Head, or principal Part of the Leek; but whether by long cultivating they may not alter I cannot poſitively affirm, having never ſown the Seeds of the latter Sort above one Year.

Theſe Plants are cultivated by ſowing their Seeds in the *Spring*, in the ſame manner as was directed for *Onions*, with which theſe are commonly ſown, the two Sorts of Seeds being mix'd according to the Proportion which is deſired of either Sort; tho' the moſt common Method is, to mix an equal Quantity of both, for the *Onions* will greatly out-grow the *Leeks* in the *Spring*; but theſe being drawn off in *July*, the *Leeks* will have time to grow large afterwards, ſo that there may be a moderate Crop of both Sorts. The management of *Leeks* being exactly the ſame with *Onions*, I ſhall not repeat it in this Place, but ſhall only add, that many Perſons do ſow their *Leeks* very thick in Beds in the *Spring*; and in *June*, after ſome of their early Crops are taken off, they dig up the Ground, and plant their *Leeks* out thereon, in Rows a Foot apart, and ſix Inches aſunder in the Rows, obſerving to water them until they have taken Root; after which they will require no farther Culture, but to clear the Ground from Weeds: The *Leeks* thus planted, will grow to a great Size, provided the Ground be good; and this Method is very proper for ſuch Perſons who have little Room.

If you would ſave the Seeds of this Plant, you ſhould make Choice of ſome of the largeſt and beſt you have, which muſt remain in the Place where they grew, until *February*; when they ſhould be tranſplanted in a Row againſt a warm Hedge, Pale or Wall, at about eight Inches aſunder; and when their Stems advance, they ſhould be ſupported by a String to prevent their being broke down, to which they are very liable, eſpecially when in Head, and the cloſer they are drawn to the Fence, in *Autumn*, the better the Seeds will ripen; for it ſometimes happens, in cold *Summers* or *Autumns*, that thoſe which grow in the open Garden, do not perfect their Seeds in this Country, eſpecially if there ſhould be ſharp Froſts early in *Autumn*, which will intirely ſpoil the Seed.

When it is ripe, (which may be known by the Heads changing brown) you ſhould cut off their Heads with about a Foot or more of the Stalk to each, and tie them in Bundles, three or four Heads in each, and hang them up in a dry Place, where they may remain till *Chriſtmas*, or after, when you may threſh out the Seeds for uſe. The Huſk of theſe Seeds is very tough, which renders it very difficult to get out the Seeds, therefore ſome Perſons who have but a ſmall Quantity, do rub it hard againſt a rough Tile, which which will break the Huſks, and get the Seeds out better than moſt other Methods I have known uſed.

PORTULACA: Purſlane.

The *Characters* are;

The Flower conſiſts of many Leaves, which expand in Form of a Roſe; *out of whoſe Flower-cup (which conſiſts of one Leaf) ariſes the Pointal, which, together with the Flower-cup, becomes a Fruit for the moſt part oval, full of ſmall Seeds, and furniſh'd with two Shells or Huſks at top; of which the outer one, which was the part of the Flower-cup that was ſplit in two, opens firſt; and the inner one, which is the Pointal enlarg'd, opens laſt, doubly and tranſverſly, while the lower Part of the Flower-cup adheres to the Footſtalk.*

The *Species* are;

1. PORTULACA *latifolia ſeu ſativa. C. B. P.* Broad leav'd *or* Garden Purſlane.

2. PORTULACA *ſativa latifolia, foliis flavis. Mor. Hiſt.* Broad-leav'd Garden Purſlane, with yellow Leaves.

3. Portulaca *anguſtifolia ſive ſylveſtris. C. B. P.* Narrow-leav'd *or* Wild Purſlane.

4. Portulaca *Curaſſavica, folio capparidis. Par. Bat.* Purſlane from Curaſſo, with a Caper-leaf.

The firſt Sort here mention'd, is what the Gardeners near *London* do chiefly cultivate; though the ſecond Sort does very ofen come up mix'd with the firſt; but whether it is only an accidental Variety ariſing from the ſame Seeds, or that the Seeds are promiſcuouſly ſav'd, I can't determine: Indeed, there is no other Difference between them, but only the Colour of their Leaves, ſo that they are both equally good for Uſe; but the green Sort having a better Appearance, is generally preferr'd in the Markets.

The wild Sort is not a Native of *England*, but grows plentifully in many warm Countries; where when it has once obtain'd ſo as to ſhed its Seeds, 'tis very difficult to extirpate again. This is ſeldom us'd; though 'tis not different from the Garden-kind, except in the Smallneſs of its Leaves.

The fourth Sort is very common in moſt of the warm Parts of *America*, where it grows in great Plenty upon the Shores and Rocks near the Sea. This is preſerved in ſome curious Gardens for Variety, but is a Plant of no great Beauty.

Purſlane is propagated from Seeds, which may be ſown upon Beds of light rich Earth during any of the *Summer* Months; but if you intend to have it early in the Seaſon, it ſhould be ſown upon a Hot-bed, for it is too tender to be ſown in the open Air before *April*, and then it muſt be in a warm Situation. This Seed is very ſmall, ſo that a little of it will be ſufficient to ſupply a Family. There is no other Culture which this Plant requires, but to keep it clear from Weeds, and in dry Weather to water it twice or three times a Week. In warm Weather this Plant will be fit for Uſe in ſix Weeks after ſowing; ſo that, in order to continue a Succeſſion of this Plant, you ſhould ſow it at three or four different Seaſons, allowing a Fortnight between each Sowing, which will be ſufficient to laſt the whole Seaſon, while it is proper to be eaten; for it being of a very cold Nature, it is unſafe to be eaten, except in the Heat of *Summer*, in *England*; for which Reaſon, it is not to any Purpoſe to ſow it upon a Hot-bed, ſince it will come early enough for Uſe in the open Air.

PRIMULA VERIS: [This Plant is ſo call'd, becauſe it is the firſt Plant that appears in the *Spring*] Primroſe.

The *Characters* are;

The Flower conſiſts of one Leaf; the lower Part of which is tubuloſe, but the upper Part expands itſelf flat in Form of a Salver, and is cut into ſeveral Segments; from the Flower-cup (which is fiſtulous) ariſes the Pointal; which, when the Flower is decay'd, becomes an oblong Fruit or Husk, lying almoſt conceal'd in the Flower-cup, and opens at the Top, in which are contain'd many roundiſh Seeds faſten'd to the Placenta.

The *Species* are;

1. Primula Veris *vulgaris. Park.* Common Primroſe.

2. Primula Veris *Conſtantinopolitana, flore albo. Tourn.* Primroſe of Conſtantinople, with a white Flower, *commonly call'd* The Paper White Primroſe.

3. Primula Veris *Conſtantinopolitana, flore dilute carneo. Tourn.* Primroſe of Conſtantinople, with a pale fleſh-colour'd Flower.

4. Primula Veris *Conſtantinopolitana, flore dilute purpureo. Tourn.* Primroſe of Conſtantinople, with a pale-purple Flower.

5. Primula Veris *Conſtantinopolitana, flore albo duplici.* Primroſe of Conſtantinople, with a double white Flower, *commonly call'd* The Double Paper-white Primroſe.

6. Primula Veris *vulgaris, flore dilute purpureo.* Common Primroſe, with a pale-purple Flower.

7. Primula Veris *vulgaris, flore pleno.* Common Primroſe, with a very double Flower.

8. Primula Veris *vulgaris, flore pleno, dilute rubente.* Common Primroſe, with a double pale-red Flower.

9. Primula Veris *pallido flore, elatior. Cluſ.* Common Pagils or Cowſlips.

10. Primula Veris *umbellata odorata pratenſis.* Great Cowſlips *or* Oxſlips.

11. Primula Veris *geminato flore. H. Eyſt.* Double Cowſlip or Hoſe in Hoſe.

12. Primula Veris *caulifera, flore luteo pleno odorato. J. B.* Cowſlip or Pagil, with a very double Flower.

13. Primula Veris *hortenſis umbellata, caule & flore folioſo coccineo majore. H. L.* Garden Primroſe or Polyanthus, with a large red Flower.

14. Primula Veris *umbellatæ odoratæ hortenſis ſimplicis varietas uberrima pro varietate jucundiſſima, coloris multiplicis. Boerh. Ind.*

There are a great Variety of the Garden *Primroſes* or *Polyanthus's*, which are annually produc'd from Seeds; the Flowers of which are ſo beautifully ſtrip'd, and ſome of them have a great Number of Flowers upon a Stalk, ſo that they equal the *Auricula's* in the Beauty of their Flowers and as they require but little Culture, ſo they have, in many Gardens, obtain'd the Preference to moſt other *Spring* Flowers.

The firſt Sort of *Primroſe* grows wild in Woods and other ſhady Places in moſt Parts of *England*, from whence their Roots may be eaſily tranſplanted into the Garden; where, if they are placed under Hedges, and in ſhady Walks, they make a beautiful Appearance early in the *Spring*, when few other Plants are in Flower.

The beſt time to tranſplant them is at *Michaelmas*, that their Roots may have Strength to produce their Flowers early in the *Spring*. Theſe delight in a ſtrong, rich Soil, but will grow in almoſt any Sort of Earth, provided they have a ſhady Situation.

The ſixth, ſeventh, and eighth Sorts are Varieties of the firſt, which have been accidentally produc'd from Seeds: Theſe may be propagated by parting of their Roots at *Michaelmas*, and muſt be treated as the common Sort.

The ninth and tenth Sorts, do alſo grow wild in the Meadows in divers parts of *England*, the Roots of which are often tranſplanted into Gardens; where, if they are intermix'd with other early flowering Plants, they afford an agreeable Variety.

The eleventh and twelfth Sorts are Varieties which were produc'd from Seeds of the former; but the laſt is, at preſent, very rare in *England*. Theſe may be propagated by parting their Roots at *Michaelmas*, and ſhould be planted on a ſtrong Soil, and expos'd to the Morning Sun.

The ſeveral Varieties of *Polyanthus's* are produc'd by ſowing of Seeds, which ſhould be ſav'd from ſuch Flowers as have good Properties, *i. e.* ſuch as have large upright Stems, producing many Flowers upon a Stalk, the Flowers large, beautifully ſtrip'd, and that open flat: From the Seeds of ſuch Flowers, there is room to hope for a great Variety of good Sorts.

Theſe Seeds ſhould be ſown in Boxes fill'd with light rich Earth, in *December*, being very careful not to bury the Seed too deep, for if it be only cover'd with light Earth it will be ſufficient: Theſe Boxes ſhould be plac'd where they may receive the Benefit of the Morning Sun until ten of the Clock, but they muſt by no means be expos'd to the Heat of the Day, eſpecially when the Plants begin to appear, for at that time one whole Day's Sun will intirely deſtroy them: In the *Spring*, if the Seaſon ſhould prove dry, you muſt often refreſh them with Water; and as the Heat increaſes, ſo you ſhould remove the Boxes more in the Shade, for the Heat is very injurious to them.

In *May* theſe Plants will be ſtrong enough to plant out; at which time you ſhould prepare ſome ſhady Borders, which ſhould be made rich; upon which you muſt ſet the Plants about four Inches aſunder, obſerving to water them until they have taken Root; after which they will require no farther Care but to keep them clear from Weeds, until the Latter-end of *Auguſt* following; when you ſhould prepare ſome Borders, which are expos'd to the Eaſt, with good light rich Earth, into which you muſt tranſplant your *Polyanthus's*, placing them ſix Inches aſunder equally in Rows, obſerving, if the Seaſon proves dry, to water them until they have taken Root. In theſe Borders your Plants will flower the ſucceeding *Spring*; at which time you muſt obſerve to mark ſuch of them as are fine, to preſerve, and the reſt may be tranſplanted into Wilderneſſes, and other ſhady Places in the Garden; where, although they are not very valuable Flowers, they will afford an agreeable Variety.

Thoſe which you intend to preſerve, may be removed ſoon after they have done flowering (provided you do not intend to ſave Seeds from them) and may be then parted and tranſplanted into a freſh Border of the like rich Earth, allowing them the ſame Diſtance as before; obſerving alſo to water them until they have taken Root, after which they will require no farther Care, but only to keep them clean from Weeds; and the following *Spring* they will produce ſtrong Flowers; and if the Kinds are good, will be little inferior to a Shew of *Auricula's*.

Theſe Roots ſhould be conſtantly removed and parted every Year, and the Earth of the Border changed, otherwiſe

wiſe they will degenerate and loſe the greateſt Part of their Beauty.

If you intend to ſave Seeds, which is the Method to obtain a great Variety, you muſt mark ſuch of them, which, as I ſaid before, have good Properties: Theſe ſhould be, if poſſible, ſeparated from all ordinary Flowers, for if they ſtand ſurrounded with plain-colour'd Flowers, they will impregnate each other, whereby the Seeds of the valuable Flowers will not be near ſo good, as if the Plants had been in a ſeparate Border where no ordinary Flowers grew; therefore the beſt Way is to take out the Roots of ſuch as you do not eſteem, ſo ſoon as the Flowers open, and plant them in another Place, that there may be none left in the Border, but ſuch as you would chuſe for Seeds.

The Flowers of theſe ſhould not be gathered, except ſuch as are produced ſingly upon Pedicles, leaving all ſuch as grow in large Bunches; and if the Seaſon ſhould prove dry, you muſt now and then refreſh them with Water, which will cauſe their Seeds to be larger and in greater Quantity, than if they were intirely neglected. Towards the Latter-end of *May* the Seed will be ripe, which may be eaſily known by the Pods changing brown and opening; ſo that you ſhould at that Time look over it three times a Week, gathering each time ſuch of it as is ripe, which ſhould be laid upon a Paper to dry, and may then be put up until the Seaſon of Sowing.

PRIMROSE-TREE, *vide* Onagra.

PRIVET, *vide* Liguſtrum.

PRUNING OF TREES: There is not any Part of Gardening, which is of more general Uſe than that of *Pruning*; and yet it is very rare to ſee Fruit-Trees ſkilfully manag'd; almoſt every Gardener will pretend to be a Maſter of this Buſineſs, though there are but few who rightly underſtand it; nor is it to be learn'd by Rote, but requires a ſtrict Obſervation of the different manners of Growth of the ſeveral Sorts of Fruit Trees; ſome requiring to be manag'd one way, and others muſt be treated in a quite different Method, which is only to be known from carefully obſerving how each Kind is naturally diſpos'd to produce its Fruit: For ſome Sorts do produce their Fruit on the ſame Year's Wood, as *Vines*; others produce their Fruit, for the moſt part, upon the former Year's Wood, as *Peaches*, *Nectarines*, &c. and others upon Curſons or Spurs, which are produced upon Wood of three, four, or five Years old, as *Pears*, *Plums*, *Cherries*, &c. therefore in order to the right Management of Fruit-Trees, there ſhould always be Proviſion made to have a ſufficient Quantity of bearing Wood, in every Part of the Trees, and at the ſame time, there ſhould not be a Superfluity of uſeleſs Branches, which would exhauſt the Strength of the Trees, and cauſe them to decay in a few Years.

The Reaſons which have been laid down for *Pruning* of Fruit-Trees, are as follow; Firſt, to preſerve Trees longer in a vigorous bearing State; the ſecond is, to render the Trees more beautiful to the Eye; and thirdly, to cauſe the Fruit to be larger and better taſted.

1. It preſerves a Tree longer in a healthy bearing State, by *Pruning* off all ſuperfluous Branches, whereby there are no more left upon the Tree than is neceſſary, or that the Roots can nouriſh kindly; ſo that the Root is not exhauſted in ſupplying uſeleſs Branches, which muſt afterwards be cut out, and thereby conſequently much of the Sap expended to no Purpoſe.

2. By ſkilful *Pruning* of a Tree, it is rendered much more pleaſing to the Eye; but I would not be underſtood to be an Advocate for a Sort of *Pruning*, which I have ſeen too much practis'd of late, *viz.* the drawing of a regular Line againſt the Wall, according to the Shape or Figure they would reduce the Tree to, and cut all the Branches, whether ſtrong or weak, exactly to the chalk'd Line; the Abſurdity of which Practice, will ſoon appear to every one who will be at the Pains of obſerving the Difference of thoſe Branches ſhooting the ſucceeding *Spring*. All therefore that I mean by rendring a Tree beautiful, is, that the Branches are all *prun'd* according to their ſeveral Strengths, and are nail'd at equal Diſtances, in proportion to the different Sizes of their Leaves and Fruit; and that no Part of the Wall (ſo far as the Trees are advanc'd) be left unfurniſhed with bearing Wood. A Tree well manag'd, though it does not repreſent any regular Figure, yet will appear very beautiful to the Sight, when it is thus dreſs'd and nail'd to the Wall.

3. It is of great Advantage to the Fruit; for the cutting away all uſeleſs Branches, and ſhortening all the bearing Shoots, according to the Strength of the Tree, does render the Tree more capable to nouriſh thoſe which are left remaining, ſo that the Fruit will be much larger, and better taſted. And this is the Advantage which thoſe Trees againſt Walls or Eſpaliers have, to ſuch as are Standards, and are permitted to grow as they are naturally inclined; for it is not their being trained either to a Wall or Eſpalier, which renders their Fruit ſo much better than Standards, but becauſe they have a leſs Quantity of Branches and Fruit for their Roots to nouriſh, and ſo conſequently their Fruit will be larger and better taſted.

The Reaſons for *Pruning* being thus exhibited, the next Thing is the Method of performing it; but this being fully handled under the ſeveral Articles of the different Kinds of Fruit, I ſhall not repeat it again in this Place, and therefore ſhall only add ſome few general Inſtructions, which are neceſſary to be underſtood, in order to the right management of Fruit-Trees.

There are many Perſons who ſuppoſe, that if their Fruit Trees are but kept up to the Wall or eſpalier, during the Summer-ſeaſon, ſo as not to hang in very great Diſorder, and in *Winter* to get a Gardener to *prune* them, it is ſufficient: But this is a very great Miſtake; for the greateſt Care ought to be employed about them in the *Spring*, when the Trees are in vigorous Growth; which is the only proper Seaſon, to procure a Quantity of good Wood in the different Parts of the Tree, and to diſplace all uſeleſs Branches, ſo ſoon as they are produced, whereby the Vigour of the Tree will be intirely diſtributed to ſuch Branches only, as are deſign'd to remain, which will render them ſtrong, and more capable to produce good Fruit: whereas, if all the Branches are permitted to remain, which are produced, ſome of the more vigorous will attract the greateſt Share of the Sap from the Tree, whereby they will be too luxuriant for producing Fruit, and the greateſt Part of the other Shoots will be ſtarved, and rendered ſo weak, as not to be able to produce any thing elſe but Bloſſoms and Leaves (as hath been before-mention'd) ſo that it is impoſſible for a Perſon, let him be ever ſo well ſkill'd in Fruit-Trees, to reduce them into any tolerable Order by *Winter-pruning* only, if they are wholly neglected in the *Spring*.

There are others, who do not intirely neglect their Trees during the *Summer* Seaſon, as thoſe before-mentioned; but yet do little more good to them by what they call *Summer-pruning*; for theſe Perſons neglect their Trees at the proper Seaſon, which is in *May*, when their Shoots are produced, and do only about *Midſummer* go over them, nailing in all their Branches, except ſuch as are produced fore-right from the Wall, which they cut out; and at the ſame time do often ſhorten moſt of the other Branches; all which is intirely wrong Practice; for thoſe Branches which are intended for bearing the ſucceeding Year, ſhould not be ſhortened during the Time of their Growth, which will cauſe them to produce two lateral Shoots from the Eyes below the Place where they were ſtopp'd, which Shoots will draw much of the Strength from the Buds of the firſt Shoot, whereby they are often flat, and do not produce their Bloſſoms, and if thoſe two lateral Shoots are not intirely cut away at the *Winter-pruning*, they will prove injurious to the Tree. And in this Method, ſuffering thoſe luxuriant Shoots to remain upon the Tree until *Midſummer*, before they are diſplaced, they will exhauſt a great Share of the Nouriſhment from the other Branches (as was before obſerved); and by ſhading the Fruit all the *Spring* Seaſon, when they are cut away, and the other Branches faſtened to the Wall, the Fruit, by being ſo ſuddenly expoſed, will receive a very great Check, which will cauſe their Skins to grow tough, and thereby render them leſs delicate. This is to be chiefly underſtood of Stone-Fruit and *Grapes*; but *Pears* and *Apples* being much hardier, do not ſuffer ſo much, though it is a great Diſadvantage to thoſe alſo to be thus managed.

It muſt alſo be remark'd, that *Peaches*, *Nectarines*, *Apricocks*, *Cherries* and *Plums*, are always in the greateſt Vigour, when they are the leaſt maim'd by the Knife; for where theſe Trees have large Amputations, they are very ſubject to gum and decay; ſo that it is certainly the moſt prudent Method, carefully to rub off all uſeleſs Buds when they are firſt produced, and pinch others, where new Shoots are wanted to ſupply the Vacancies of the Wall; by which Management Trees may be ſo ordered, as to want but little of the Knife in *Winter-pruning*, which is the ſureſt Way to preſerve theſe Trees healthful, and is perform'd with leſs Trouble than the common Method.

The Management of *Pears* and *Apples*, is much the ſame with theſe Trees in *Summer*, but in *Winter* they muſt be very differently *pruned*; for as *Peaches* and *Nectarines* do, for the moſt part, produce their Fruit upon the former Year's Wood, and therefore muſt have their Branches ſhortened according to their Strength, in order to produce new Shoots for the ſucceeding Year; ſo *Pears* and *Apples*, on the contrary, producing their Fruit upon *Curſons* or *Spurs*, which come out of the Wood of five, ſix or ſeven Years old; ſhould not be ſhortened, becauſe thereby thoſe Buds which were naturally diſpoſed to form theſe *Curſons* or *Spurs*, would produce Wood-Branches, whereby the Trees would be fill'd with Wood, but never produce much Fruit; and as it often happens that the Bloſſom-buds are firſt produced at the Extremity of the laſt Year's Shoot, ſo by ſhortening the Branches, the Bloſſoms are cut away, which ſhould always be carefully avoided.

There are ſeveral Authors who have written on the ſubject of *Pruning* in ſuch a prolix manner, that it is impoſſible for a Learner to underſtand their Meaning; theſe have deſcribed the ſeveral Sorts of Branches, which are produced on Fruit-trees; as *Wood-Branches*, *Fruit-Branches*, *Irregular-Branches*, *Falſe-Branches*, and *Luxuriant-Branches*, all which they aſſert, every Perſon who pretends to *Pruning* ſhould diſtinguiſh well: Whereas there is nothing more in all this but a Parcel of Words to amuſe the Reader, without any real Meaning; for all theſe are comprehended under the Deſcription already given of luxuriant or uſeleſs Branches, and ſuch as are termed uſeful or Fruit-bearing Branches, and where due Care is taken in the *Spring* of the Year, to diſplace theſe uſeleſs Branches (as was before directed) there will be no ſuch Thing as *irregular*, *falſe*, or *luxuriant Branches*, at the *Winter-pruning*; therefore it is to no purpoſe to amuſe People with a Cant of Words, which, when fully underſtood, ſignify juſt nothing at all.

But ſince I have explained the different Methods of *Pruning* the ſeveral Sorts of Fruits, under their reſpective Articles, I ſhall forbear repeating it again in this Place; but ſhall only give ſome general Hints for the *Pruning* of Standard Fruit-trees, and ſo conclude.

Firſt, you ſhould never ſhorten the Branches of theſe Trees, unleſs it be where they are very luxuriant, and grow irregular on one Side of the Tree, attracting the greateſt Part of the Sap of the Tree, whereby the other Parts are unfurniſhed with Branches, or are rendered very weak; in which Caſe the Branch ſhould be ſhortened down ſo low as is neceſſary, in order to obtain more Branches, to fill up the Hollow of the Tree; but this is only to be underſtood of *Pears* and *Apples*, which will produce Shoots from Wood of three or four Years old; whereas moſt Sorts of Stone-fruit will gum and decay after ſuch Amputation.

But from hence I would not have it underſtood, that I would direct the reducing of theſe Trees into an exact ſpherical Figure, ſince there is nothing more deteſtable, than to ſee a Tree (which if permitted will grow as it is naturally diſpoſed, with its Branches produced at proportionable Diſtances, according to the Size of the Fruit) by endeavouring to make it exactly regular in its Head, ſo crowded with ſmall weak Branches as to prevent the Air from paſſing between them; which will render it incapable to produce Fruit; all that I intend by this ſtopping of luxuriant Branches, is only when one or two ſuch happen on a young Tree, where they intirely draw all the Sap from the weaker Branches and ſtarve them; and then it is proper to uſe this Method, which ſhould be done in time, before they have exhauſted the Roots too much.

Whenever this happens to Stone-fruit, which ſuffer much more by cutting than the former Sorts, it ſhould be remedied by ſtopping or pinching thoſe Shoots in the *Spring*, before they have obtained too much Vigour; which will cauſe them to puſh out Side-branches, whereby the Sap will be diverted from aſcending too faſt to the leading Branch (as hath been directed for Wall-trees); but this muſt be done with Caution, as before.

You muſt alſo cut out all dead or decaying Branches, which cauſe their Heads to look very ragged, eſpecially at the Time when the Leaves are upon the Tree, theſe being deſtitute of them have but a deſpicable Appearance; beſides, theſe do attract noxious Particles from the Air, which are injurious to the Trees; therefore the ſooner they are cut out the better; in doing of this you ſhould obſerve to cut them cloſe down to the Place where they were produced, otherwiſe that Part of the Branch left will decay and prove equally hurtful to the Tree; for it ſeldom happens that when a Branch begins to decay, that it does not die quite down to the Place where it was produced, and if permitted to remain long uncut, does often infect ſome of the other Parts of the Tree. If the Branches are large which you cut off, it will be very proper, after having ſmoothed the cut Part exactly even with a Knife, Chiſſel or Hatchet, to put on a Plaiſter of grafting Clay, which will prevent the Wet from ſoaking into the Tree, at the wounded Part.

All ſuch Branches which run croſs each other, ſhould alſo be cut out; for theſe not only occaſion a Confuſion in the Head of the Tree, but by lying over each other, do rub off their Bark by their Motion, and very often occaſion them to canker, to the great Injury of the Tree; and on old Trees (eſpecially *Apples*) there are often young vigorous Shoots produced from the old Branches near the Trunk, which grow upright into the Head of the Trees; theſe therefore ſhould carefully be cut out every Year, leſt by being permitted to grow they fill the Tree too full of Wood, which ſhould always be guarded againſt, ſince it is impoſſible for ſuch Trees to produce ſo much, or ſo good Fruit, as thoſe Trees whoſe Branches grow at a farther Diſtance, whereby the Sun and Air do freely paſs between them, in every Part of the Tree.

Theſe are all the general Directions which are proper to be given in this Place, ſince not only the particular Methods, but alſo the proper Seaſons for *Pruning* all the different Kinds of Fruit, are fully exhibited under their ſeveral Articles.

PRUNUS. The Plum-Tree.

The *Characters* are;

The Flower conſiſts of five Leaves, which are placed in a circular Order, and expand in Form of a Roſe: *from whoſe Flower-cup riſes the Pointal, which afterwards becomes an oval or globular Fruit, having a ſoft fleſhy Pulp, ſurrounding a hard oblong Stone, for the moſt part pointed; To which ſhould be added, The Foot-ſtalks are long and ſlender, and have but a ſingle Fruit upon each.*

The *Species* are;

1. PRUNUS *fructu parva præcoci. Tourn.* The Jean-hative, or White Primordian. This is a ſmall white *Plum*, of a clear yellow Colour, covered over with a white Flew, which eaſily wipes off; it is a pretty good Bearer, and for its coming very early, deſerves a Place in every good Garden of Fruit. This ripens the Beginning of *July*.

2. PRUNUS *fructu magno craſſo ſubacido. Tourn. Damas noir hative*, i. e. The early black Damaſk, *commonly called* The Morocco Plum. This is a pretty large *Plum* of a round Shape, divided with a Furrow in the Middle (like *Peaches*); the Outſide is of a dark black Colour, covered with a light violet Bloom, the Fleſh is yellow, and parts from the Stone. It ripens in the Middle of *July*.

3. PRUNUS *fructu parvo dulci-atro cæruleo. Tourn.* The little black Damaſk Plum. This is a ſmall black *Plum*, covered over with a violet Bloom; the Juice is richly ſugared, the Fleſh parts from the Stone, and it is a good Bearer. Ripe the Middle of *July*.

4. PRUNUS *fructu magno dulci atro-cœruleo. Tourn. Groſ. Damas Violet de Tours*, i. e. Great Damaſk Violet of Tours. This is a pretty large *Plum*, inclining to an oval Shape, the Outſide is of a dark blue, covered with a violet Bloom; the Juice is richly ſugared, and the Fleſh parts from the Stone. Ripe the Middle of *July*.

5. PRUNUS *fructu rotundo atro-rubente.* The Orleans Plum. The Fruit is ſo well known to almoſt every Perſon, that it is needleſs to deſcribe it; it is a very plentiful Bearer, which has occaſioned its being ſo generally planted by thoſe Perſons who ſupply the Markets with Fruit; but it is an indifferent *Plum*.

6. PRUNUS *fructu oblongo atro-rubente.* The Fotheringham Plum. This Fruit is ſomewhat long, deeply furrow'd in the Middle; the Fleſh is firm, and parts from the Stone; the Juice is very rich. This ripens about the Middle of *July*.

7. PRUNUS *fructu nigro, carne dura. Tourn.* The Perdrigon Plum. This is a middle-ſized *Plum*, of an oval Shape, the Outſide is of a very dark Colour, covered over with a violet Bloom; the Fleſh is firm, and full of an excellent rich Juice; this is greatly eſteemed by the Curious. Ripe the Latter-end of *July*.

8. PRUNUS *fructu magno e violaceo rubente ſuaviſſimo ſaccharato. Tourn.* The Violet Perdrigon Plum. This is a large Fruit rather round than long, of a bluiſh-red Colour on the out-ſide; the Fleſh is of a yellowiſh Colour, pretty firm, and cloſely adheres to the Stone; the Juice is of an exquiſite rich Flavour. This ripens the End of *July*.

9. PRUNUS *fructu ovato ex albo flaveſcente.* The white Perdrigon Plum. This is a middling Plum, of an oblong Figure, the Outſide is yellow, covered with a white Bloom; the Fleſh is firm and well-taſted: it is a very good Fruit to eat raw, or for Sweetmeats, having an agreeable Sweetneſs mixed with an Acidity.

10. PRUNUS *fructu ovato magno rubente. Tourn.* The red Imperial Plum, *ſometimes called* the Red Bonum Mag-

num. This is a large oval-ſhaped Fruit, of a deep red Colour, covered with a fine Bloom; the Fleſh is very dry, and very indifferent to be eaten raw; but is excellent for making Sweetmeats: This is a great Bearer. Ripe the End of *July*.

11. PRUNUS *fructu ovato magno flaveſcente. Tourn.* White Imperial Bonum Magnum; White Holland or Mogul Plum. This is a large oval-ſhaped Fruit, of a yellowiſh Colour, powdered over with a white Bloom; the Fleſh is firm, and adheres cloſely to the Stone; the Juice is of an acid Taſte, which renders it unpleaſant to be eaten raw; but it is very good for Baking or Sweetmeats: It is a good Bearer, and is ripe towards the End of *Auguſt*.

12. PRUNUS *fructu ovato cœruleo.* The Cheſton Plum. This is a middle-ſized Fruit, of an oval Figure, the Outſide is of a dark blue, powdered over with a violet Bloom; the Juice is rich, and it is a great Bearer. Ripe the End of *July*.

13. PRUNUS *fructu maximo rotundo flavo & dulci. Tourn. Prune d'Abricot.* i. e. the Apricock Plum. This is a large round Fruit, of a yellow Colour on the Out-ſide, powder'd over with a white Bloom; the Fleſh is firm and dry, of a ſweet Taſte, and comes clean from the Stone. This ripens the End of *July*.

14. PRUNUS *fructu ſubrotundo, ex rubro & flavo mixto.* The Maitre Claud. This is a middle-ſized Fruit, rather round than long, of a fine mixed Colour, between red and yellow; the Fleſh is firm, and parts from the Stone, and has a delicate Flavour. Ripe the End of *July*.

15. PRUNUS *fructu rubente dulciſſimo. Tourn.* La Roche-Courbon, *or* Diapree-rouge, *i. e.* the Red Diaper Plum. This is a large round Fruit, of a reddiſh Colour, powdered over with a violet Bloom; the Fleſh adheres cloſely to the Stone, and is of a very high Flavour. Ripe in the Beginning of *Auguſt*.

16. PRUNUS *fructu rotundo flaveſcente.* La Reine Claude, *i. e.* Queen Claudia. This is a ſmall round Fruit, of a yellowiſh Colour, powder'd over with a pearl-coloured Bloom; the Fleſh is firm and thick, quits the Stone, and its Juice is richly ſugar'd. Ripe the Middle of *Auguſt*.

17. PRUNUS *fructu rotundo nigro-purpureo majori dulci. Tourn.* Myrabolan Plum. This is a middle-ſized Fruit, of a round Shape, the Outſide is a dark purple, powdered over with a violet Bloom; the Juice is very ſweet. It is ripe the Middle of *Auguſt*.

18. PRUNUS *fructu rotundo e viridi flaveſcente, carne dura, ſuaviſſimo.* The Green Gage Plum. This is one of the beſt *Plums* in *England*: it is of a middle Size, round, and of a yellowiſh-green Colour on the Outſide; the Fleſh is firm, of a deep green Colour, and parts from the Stone; the Juice has an exceeding rich Flavour, and it is a great Bearer. Ripe the End of *July*. This is called *Gros Damas Verd*, i. e. the *Great Green Damaſk*, in *France*.

19. PRUNUS *fructu amygdalino. Tourn.* Rognon de Coq; *i. e.* Cock's Teſticles. This is an oblong Fruit, deeply furrowed in the Middle, ſo as to reſemble the Teſticles; it is of a whitiſh Colour on the Outſide, ſtreaked with red; the Fleſh of it adheres firmly to the Stone, and it is late ripe.

20. PRUNUS *fructu rotundo flavo dulciſſimo.* Drap d' Or, *i. e.* the Cloth of Gold Plum. This is a middle-ſized Fruit, of a bright yellow Colour, ſpotted or ſtreaked with red on the Outſide; the Fleſh is yellow, and full of an excellent Juice; it is a plentiful Bearer, and ripens about the End of *July*.

21. PRUNUS *fructu cerei coloris. Tourn.* Prune de Sainte Catherine, *i. e.* St. Catharine Plum. This is a large oval-ſhaped Fruit, ſomewhat flat; the Outſide is of an Amber Colour, powdered over with a whitiſh Bloom, but the Fleſh is of a bright yellow Colour, is dry and firm, adheres cloſely to the Stone, and has a very agreeable ſweet Taſte. This ripens at the End of *Auguſt*, and is very ſubject to dry upon the Tree, when the *Autumn* proves warm and dry. This makes fine Sweetmeats, and is a plentiful Bearer.

22. PRUNUS *fructu ovato rubente dulci.* The Royal Plum. This is a large fruit, of an oval Shape, drawing to a Point next the Stalk; the Outſide is of a light red Colour, powdered over with a whitiſh Bloom; the Fleſh adheres to the Stone, and has a fine ſugary Juice. This ripens the End of *July*.

23. PRUNUS *fructu parvo ex viridi flaveſcente. Tourn.* La Mirabelle. This is a ſmall, round Fruit, of a greeniſh yellow on the Outſide; the Fleſh parts from the Stone, is of a bright yellow Colour, and has a fine ſugary Juice. This is a great Bearer, and ripens the Beginning of *Auguſt*.

24. PRUNUS *Brignonienſis, fructu ſuaviſſimo. Tourn.* Prune de Brignole, *i. e.* the Brignole Plum. This is a large oval-ſhaped Fruit, of a yellowiſh Colour, mixed with red on the Outſide; the Fleſh is of a bright yellow Colour, is dry, and of an excellent rich Flavour. This ripens the Middle of *Auguſt*, and is eſteemed the beſt *Plum* for Sweetmeats yet known.

25. PRUNUS *fructu magno e violaceo rubente ſerotino. Tourn.* Imperatrice, *i. e.* the Empreſs. This is a large, round Fruit, of a violet-red Colour, very much powdered with a whitiſh Bloom; the Fleſh is yellow, cleaves to the Stone, and is of an agreeable Flavour. This ripens about the Middle of *September*.

26. PRUNUS *fructu ovato maximo flavo. Tourn.* Prune de Monſieur, *i. e.* the Monſieur Plum. This is ſometimes called the *Wentworth* Plum. It is a large, oval-ſhaped Fruit, of a yellow Colour both within and without, very much reſembling the *Bonum Magnum*; but the Fleſh of this parts from the Stone, which the other doth not. This ripens towards the Latter-end of *Auguſt*, and is very good to preſerve, but the Juice is too ſharp to be eaten raw; it is a great Bearer.

27. PRUNUS *fructu majori rotundo rubro. Tourn.* Prune Cerizette, *i. e.* the Cherry Plum. This Fruit is commonly about the Size of the *Ox-heart Cherry*, is round, and of a red Colour; the Stalk is long, like that of a Cherry, which this Fruit ſo much reſembles, as not to be diſtinguiſhed therefrom at ſome Diſtance. The Bloſſoms of this Tree come out very early in the *Spring*, and being tender, are very often deſtroyed by Cold: but it affords a very agreeable Proſpect in the *Spring*; for theſe Trees are generally covered with Flowers, which open about the ſame Time as the Almonds, ſo that when they are intermixed therewith, they make a beautiful Appearance before many other Sorts do put out; but where the Fruit is deſired they ſhould have a South-Eaſt Wall.

28. PRUNUS *fructu albo oblongiuſculo acido. Tourn.* The white Pear Plum. This is a good Fruit for Preſerving, but is very unpleaſant, if eaten raw; it is very late ripe, and ſeldom planted in Gardens, unleſs for Stocks to bud ſome tender Sorts of *Peaches* upon, for which Purpoſe it is eſteemed the beſt amongſt all the Sorts of *Plums*.

29. PRUNUS *Mytellinum. Park.* The Muſcle Plum. This is an oblong flat *Plum*, of a dark red Colour; the Stone is large, and the Fleſh but very thin, and not well-taſted, ſo that its chief Uſe is for Stocks, as the former.

30. PRUNUS *fructu parvo violaceo.* The St. Julian Plum. This is a ſmall Fruit, of a dark violet Colour, powdered over with a mealy Bloom; the Fleſh adheres cloſely to the Stone, and in a fine *Autumn* will dry upon the Tree. The chief Uſe of this *Plum* is for Stocks, to bud the more generous Kinds of *Plums* and *Peaches* upon, as alſo for the *Bruxelles* Apricock, which will not thrive ſo well upon any other Stock.

31. PRUNUS *ſylveſtris major. J. B.* The black Bullace-tree. This grows wild in the Hedges in divers Parts of *England*, and is rarely cultivated in Gardens.

32. PRUNUS *ſylveſtris, fructu majore albo. Raii Syn.* The white Bullace-tree. This grows wild as the former, and is ſeldom cultivated in Gardens.

33. PRUNUS *ſylveſtris. Ger. Emac.* The Black-thorn, *or* Sloe-tree. This is very common in the Hedges almoſt every where; the chief Uſe of this Tree is to plant for Hedges, as *White-thorn*, &c. and being of quick Growth is very proper for that Purpoſe.

All the Sorts of *Plums* are propagated by budding or grafting them upon Stocks of the *Muſcle*, *White Pear*, *St. Julian*, *Bonum Magnum*, or any other Sorts of free-ſhooting *Plums*; the Manner of raiſing theſe Stocks hath been already exhibited under the Article of *Nurſeries*, therefore need not be repeated again in this Place; but I would obſerve, that Budding is much preferable to Grafting, for theſe Sorts of Fruit-trees, which are very apt to gum, where-ever there are large Wounds made on them.

The Trees ſhould not be more than one Year's Growth from the Bud, when they are tranſplanted; for if they are older they ſeldom ſucceed ſo well, being very ſubject to canker; or if they do take well to the Ground, commonly produce only two or three luxuriant Branches; therefore it is much more adviſeable to chuſe young Plants.

The Manner of preparing the Ground (if for Walls) is the ſame as for Peaches, as is alſo the pruning the Roots and planting: and therefore I ſhall forbear repeating it again. The Diſtance which theſe Trees ſhould be planted at, muſt not be leſs than fourteen or ſixteen Feet, and if the Wall is low, they ſhould be placed eighteen Feet aſunder.

Plums ſhould have a middling Soil, neither too wet and heavy, nor over light and dry; in either of which Extremes they ſeldom do well: And thoſe Sorts which are planted againſt Walls, ſhould be placed to an Eaſt or South-Eaſt Aſpect, which is more kindly to theſe Fruits than a full South Aſpect, on which they are ſubject to ſhrivel, and be very dry, and many Sorts will be extreme mealy, if expos'd too much to the Heat of the Sun; but moſt Sorts will ripen extremely well on Eſpaliers, if rightly manag'd.

There are ſome Perſons who plant *Plums* for Standards, in which Method ſome of the ordinary Sorts will bear very well; but then the Fruit will not be near ſo fair as thoſe produced on Eſpaliers, and will be more in danger of being bruis'd or blown down by ſtrong Winds. The Diſtance of placing them for Eſpaliers muſt be the ſame as againſt Walls, as muſt alſo their Pruning and Management, ſo that whatever may be hereafter mention'd for one, ſhould be alſo underſtood for both.

Plums do not only produce their Fruit upon the laſt Year's Wood, but alſo upon Curſons or Spurs, which come out of Wood that is two or three Years old; ſo that there is not a Neceſſity of ſhortening the Branches, in order to obtain new Shoots annually, in every Part of the Tree, (as in *Peaches*, *Nectarines*, *&c.* hath been directed) ſince the more theſe Trees are pruned, the more luxuriant they grow, until the Strength of them is exhauſted, and then they gum and ſpoil: Therefore the ſafeſt method to manage theſe Trees, is, to lay in their Shoots horizontally, as they are produced, at equal Diſtances, in proportion to the Length of their Leaves; and where there is not a ſufficient Quantity of Branches to fill up the Vacancies of the Tree, there the Shoots may be pinch'd the Beginning of *May*, (in the Manner as hath been directed for *Peaches*, *&c.*) which will cauſe them to produce ſome lateral Branches to ſupply thoſe Places; and during the growing Seaſon, all foreright Shoots ſhould be diſplaced, and ſuch as are to remain muſt be regularly train'd in to the Wall or Eſpalier, which will not only render them beautiful, but alſo give to each an equal Advantage of Sun and Air: And hereby the Fruit will be always kept in a ductile, growing State, which they ſeldom are, when over-ſhaded with Shoots ſome Part of the Seaſon, and then ſuddenly expos'd to the Air, by the taking off or training thoſe Branches in their proper Poſition.

With thus carefully going over theſe Trees in the growing Seaſon, there will be but little Occaſion for cutting them in *Winter* Pruning, which (as I before have ſaid) is of ill Conſequence to all Sorts of Stone-Fruit: Beſides, many of theſe Fruits do produce Bloſſom-buds, at the Extremity of their former Year's Shoots; ſo that when thoſe are ſhortened, the Fruit is cut away, and hereby the Number of Shoots is increaſed: For whenever a Branch is ſhortened, there are commonly two or more Shoots produced from the Eyes immediately below the Cut; ſo that by thus unſkilfully Pruning, many Perſons croud their Trees with Branches, and thereby render what little Fruit the Trees do produce, very ſmall and ill-taſted, which is very commonly found in too many Gardens, where the Manager, perhaps, thinks himſelf a compleat Maſter of his Buſineſs. For nothing is more common, than to ſee every Branch of a Fruit-tree paſs the Diſcipline of the Knife, however agreeable it be to the ſeveral Sorts of Fruits.

Thoſe few Rules before laid down, will be ſufficient, if due Obſervation be join'd therewith, to inſtruct any Perſon in the right Management of theſe Sorts of Fruit-trees; therefore I ſhall not ſay any more on that Subject, leſt, by multiplying Inſtructions, it may render it more obſcure to a Learner.

PSEUDOACACIA, [of ψευδὸς *falſe*, and *Acacia*] Virginian Acacia, *vulgo*.

The *Characters* are;

It hath a papilionaceous Flower, from whoſe Flower-cup riſes the Pointal, wrapped up in a fimbriated Membrane, which afterwards becomes a Pod, opening into two Parts, in which are contained ſeveral Kidney-ſhap'd Seeds.

The *Species* are;

1. PSEUDOACACIA *vulgaris. Tourn.* Common Virginian Acacia.

2. PSEUDOACACIA *Americana latifolia, flore roſea. Plum.*

3. PSEUDOACACIA *Americana, flore pyramidato coccineo. Plum. Cat.* Falſe Acacia of *America*, with ſcarlet Flowers, growing in a Pyramid.

4. PSEUDOACACIA *Americana, ſiliquis alatis. Plum. Cat.* Falſe Acacia of *America*, with winged Pods.

5. PSEUDOACACIA *Americana latifolia, floribus purpureis. Plum. Cat.* Falſe Acacia of *America*, with a broad Leaf, and purple Flowers.

6. PSEUDOACACIA *Americana ingens, fructu coccineo, nigrâ maculâ notato. Plum. Cat.* Falſe Acacia of *America*, with a ſcarlet Fruit marked with black Spots.

7. PSEUDOACACIA *Americana, fraxini folio, floribus violaceis. Plum. Cat.* Falſe Acacia of *America*, with an Aſh-leaf, and violet-coloured Flowers.

The firſt of theſe Trees is very common in *England*, eſpecially in the Gardens near *London*, where are ſeveral very large old Trees, which have been ſeveral Years ſtanding: but the ſecond Sort is at preſent very rare in *England*.

Theſe Trees may be propagated by ſowing their Seeds in the Spring upon a Bed of light freſh Earth; and when the Plants are come up, they ſhould be carefully cleared from Weeds; and in very dry Weather, if they be refreſhed with Water, it will greatly promote their Growth: In this Bed the Plants ſhould remain 'till the latter End of *March* following, at which time they ſhould be tranſplanted out into a Nurſery, in Rows, three Feet aſunder, and the Plants eighteen Inches Diſtance in the Rows, obſerving to lay a little Mulch upon the Surface of the Ground about their Roots, to prevent the Earth's drying too faſt. During the Summer-ſeaſon you ſhould carefully clear 'em from Weeds; and if they produce irregular Branches, they ſhould be prun'd off while young. The Spring following the Ground between the Rows ſhould be carefully dug, that the Roots of the Trees may the more eaſily extend themſelves every way; and in Summer the Weeds ſhould be conſtantly hough'd down, to prevent their injuring the Plants.

When the Trees have remain'd in this Nurſery three Years, they ſhould be tranſplanted where they are deſigned to grow; for if they are permitted to remain in the Nurſery too long, they will not bear tranſplanting, their Roots creeping very far juſt under the Surface of the Earth, which when too much cut, do ſeldom abide long in Vigour.

Theſe Trees are very hardy, in reſpect to Cold; but they will not endure to be expoſed too much to ſtrong Winds, which continually break their brittle Branches, and render them unſightly; ſo that many People have neglected to cultivate theſe Trees on that Account: but when they are intermixed with other large-growing Trees, in great Wilderneſſes, they make a beautiful Variety, and in *June* they are covered with large Bunches of white ſweet-ſmelling Flowers.

Indeed, I can't recommend them for planting Avenues, which was the great Uſe they were formerly apply'd to; ſince in ſuch Places they would be greatly expoſed to the Wind, which would cauſe them to have a ragged Appearance, by the continual ſnapping of their Branches: Nor are they very proper to plant in Gardens, becauſe their Roots do extend to a great Diſtance, and emaciate the Soil; and the Numbers of Suckers, which they are apt to produce, render them very troubleſome in open Gardens: but for large Wilderneſſes they are very proper, where, if the Soil be moiſt, they will grow to a conſiderable Magnitude.

I have ſeen ſome theſe Trees upwards of forty Feet high, which have divided at a little Diſtance from the Ground, into three or four Branches, each of which have been equal to a large Tree; ſo that it ſhould not be planted too near other Trees, leſt, by its great Growth, it overſhadows and deſtroys them. In many Gardens near *London* theſe Trees have produced good Seeds, from whence a great Number of Plants have been raiſed.

The third, fifth and ſeventh Sorts, grow plentifully about *Carthagena* in *New Spain*, as alſo at *Campechy*: in both theſe Places they were obſerved by the late Dr. *William Houſtoun*, who ſent Seeds of theſe Kinds to *England*.

The ſecond Sort grows plentifully in all the low Lands of *Jamaica*, and is called by the Inhabitants *Dogwood*. The Bark of this Tree, bruiſed and thrown into ſtanding Waters, where Fiſh are, will intoxicate them for a time, ſo that they turn up their Bellies, and float on the Surface of the Water; by which Method the *Indians* and *Negro*'s take great Quantities of Fiſh, which, when caught by this Method, are eſteemed very wholeſome.

The fourth Sort is alſo pretty common in moſt of the *Engliſh* Settlements in the *Weſt-Indies*, and in the *Spaniſh Weſt-Indies* it is very common. The Seeds of this Tree are of a beautiful ſcarlet Colour, having a large black Spot on the Eye. This was formerly brought into *England* by the Name of *Anacock*.

All theſe Sorts of falſe Acacia are very tender Plants, ſo will not thrive in this Country, unleſs they are preſerved in Stoves. They may be propagated by Seeds, which ſhould be ſown early in the Spring, in Pots filled with rich Earth, and plunged into a Hot-bed of Tanners-bark; and when the Plants are come up, they ſhould be each tranſplanted into a ſeparate Pot, filled with rich Earth, and plunged again into the Hot-bed, being careful to ſhade them until they have taken new Root; after which Time they ſhould have freſh Air admitted to them every Day, in proportion to the Warmth of the Seaſon, and they muſt be frequently watered in warm Weather. With this Management the Plants will make good Progreſs, ſo that towards the End of *July*, they will have filled the Pots with their Roots; when they ſhould be ſhifted into other Pots ſomewhat larger, and may be plunged into the Hot-bed again, where they may remain till towards *Michaelmas*, when they ſhould be removed into the Stove, and plunged into the Bark-bed, where they muſt be kept warm during the winter Seaſon, and ſhould be frequently refreſhed with Water; but it muſt be given to them in ſmall Quantity in cold Weather. The following Spring theſe Plants ſhould be ſhifted into freſh Earth, and if they have made good Progreſs, they will require Pots a little larger than the former: the Hot-bed in the Stove ſhould alſo be refreſhed with ſome new Tan at this Seaſon, to renew its Heat, and the Plants plunged therein; which will cauſe them to puſh early in the Summer, ſo that they will have Time to make good Progreſs before Winter. During the Summer Seaſon, the Plants ſhould have a large Share of free Air in warm Weather, and require Plenty of Water; their Leaves ſhould alſo be frequently waſhed to cleanſe them from Filth, otherwiſe they will not grow very faſt. In two or three Years theſe Plants will produce their Flowers, when they will make an agreeable Variety amongſt other tender exotic Plants in the Stove.

The Seeds of the ſixth Sort are ſo hard as often to remain a whole Year in the Ground, before the Plants appear, eſpecially if the Earth in the Pots be not conſtantly watered; ſo that if the Pots are not preſerved in a proper Temperature of Heat in Winter, the Seeds will rot: therefore the beſt Method to make the Seeds vegetate in a ſhort time, is to lay them under a Pot of Earth in the Tan-bed, as hath been directed for the *Bonduc*, and other hard *Indian* Seeds.

PSEUDO-DICTAMNUS, [of ψευδὸς *falſe*, and *Dictamus*, *Dittany*] Baſtard-Dittany.

The *Characters* are;

It hath a labiated Flower conſiſting of one Leaf, whoſe Upper-lip or Helmet is arched, and generally cut into two Segments: but the Under-lip (or Beard) is divided into three Parts. Out of the Funnel-ſhaped Flower-cup riſes the Pointal, attended by four Embryo's, which afterwards become ſo many oblong Seeds, incloſ'd in the Flower-cup.

The *Species* are;

1. Pseudo-Dictamnus *acetabulis Moluccæ. C. B. P.* Baſtard-Dittany, with the Pan or Hollow of Molucca Balm.
2. Pseudo-Dictamnus *Hiſpanicus, ſcrophulariæ folio. Tourn.* Spaniſh Baſtard-Dittany, with a Figwort Leaf.
3. Pseudo-Dictamnus *Hiſpanicus, ampliſſimo folio, candicante & villoſo. Tourn.* Spaniſh Baſtard-Dittany, with a large, hoary, and hairy Leaf.
4. Pseudo-Dictamnus *verticillatus inodorus. C. B. P.* Whorled Baſtard-Dittany without Smell.
5. Pseudo-Dictamnus *Orientalis, foliis circinatis. T. Cor.* Eaſtern Baſtard-Dittany, with round Leaves.

There are ſeveral other Varieties of this Plant, which are preſerved in Botanick Gardens; but as they have little Beauty or Uſe, ſo it will be needleſs to enumerate them in this Place.

All theſe Plants may be propagated by Seeds, parting of their Roots, or Cuttings: but the two laſt being the moſt expeditious Methods, are generally practiſed. The beſt time to tranſplant and part their Roots, is in the *Spring*, before they begin to grow, that the Off-ſets may take Root before the dry Weather: Theſe ſhould be planted in a poor, dry Soil, where they will endure the Cold much better than if planted in a richer Ground. There is no great Beauty in theſe Plants; but as they are ſometimes preſerved by curious Perſons, I thought it proper to mention them in this Place.

PSYLLIUM, [takes its Name of Ψύλλα *a Flea*, becauſe its Seed reſembles a Flea, in Shape and Colour] Fleawort.

The *Characters* are;

This Plant agrees with Plantain and Buckſhorn Plantain in every reſpect, excepting that this riſes up with leafy Stalks, and divides into many Branches, whereas both the others produce their Flowers upon naked Pedicles.

The *Species* are;

1. Psyllium *majus erectum. C. B. P.* Greater Upright Fleawort.
2. Psyllium *majus ſupinum. C. B. P.* Greater Fleawort, whoſe Branches ſpread to the Ground.
3. Psyllium *Indicum, foliis crenatis. J. B.* Indian Fleawort, with notched Leaves.

There are ſeveral other Varieties of theſe Plants, diſtinguiſhed by Writers in Botany; but ſince they are of little Uſe or Beauty, I ſhall paſs them by without naming.

Theſe Plants may be propagated by ſowing of their Seeds in the Spring, on a Bed of light Earth; and when they are come up, they ſhould be cleared from Weeds; pulling out at the ſame time ſome of the Plants, where they ſtand too cloſe, leaving the remaining ones about eight or nine Inches aſunder: after which they will require no farther Care, but to clear 'em from Weeds; and in *June* they will flower, and their Seeds will ripen in *Autumn*.

The ſecond Sort will abide two or three Years, provided they are on a poor dry Soil; but the other two Sorts periſh every Year.

The firſt Sort, which is the moſt common, is uſed in Medicine; but the other two are never uſed in *England*.

PTARMICA, [takes its Name of Πτάρμος *Sneezing Powder*; becauſe the Head of this Plant, being powdered, is uſed for Snuff: It is alſo called *Dracunculus*, becauſe it has much the ſame Figure as *Dracunculus Hortenſis*] Sneezwort.

The *Characters* are;

It hath radiated Flowers, whoſe Disk conſiſts of many Florets, but the Borders are compos'd of Half-florets: The Embryo's are lodg'd in the Flower-cup, which is ſcaly, each of which becomes one ſlender Seed.

The *Species* are;

1. Ptarmica *vulgaris, folio longo ſerrato, flore albo. J. B.* Common Sneezwort, with a long ſerrated Leaf, and a white Flower.
2. Ptarmica *vulgaris, flore pleno. Cluſ. Hiſt.* Common Sneezwort, with a double Flower, *by ſome call'd* Double Pellitory.
3. Ptarmica *foliis profundè ſerratis, latè viridibus elatior. H. L.* Taller Sneezwort, with broad green Leaves deeply ſerrated.
4. Ptarmica *Alpina, incanis ſerratis foliis. H. L.* Alpine Sneezwort, with hoary ſerrated Leaves.
5. Ptarmica *incana, pinnulis criſtatis. T. Cor.* Hoary Sneezwort, with creſted Leaves.
6. Ptarmica *incana humilis, foliis laciniatis, abſinthii æmulis. H. L.* Dwarf-hoary Sneezwort, with jagged Leaves, reſembling Wormwood.
7. Ptarmica *Alpina, foliis anguſtis, partim ſerratis, partim integris. Bocc. Muſ.* Alpine Sneezwort, with narrow Leaves, Part of which are ſawed on their Edges, and the other Part are whole.
8. Ptarmica *Cretica fruteſcens, ſantolinæ facie. Inſt. R. H.* Shrubby Sneezwort of *Crete*, with the Appearance of Lavender-cotton.
9. Ptarmica *Orientalis, foliis criſtatis Tourn. Cor.* Eaſtern Sneezwort, with creſted Leaves.
10. Ptarmica *Orientalis, foliis criſtatis longioribus, & capitulis majoribus. Tourn. Cor.* Eaſtern Sneezwort, with longer creſted Leaves, and larger Heads.
11. Ptarmica *Orientalis, ſantolinæ folio, flore majore. Tourn. Cor.* Eaſtern Sneezwort, with a lavender-cotton Leaf, and a larger Flower.
12. Ptarmica *Orientalis, ſantolinæ folio, flore minore. Tourn. Cor.* Eaſtern Sneezwort, with a lavender-cotton Leaf, and a ſmaller Flower.
13. Ptarmica *Orientalis, foliis tanaceti incanis, flore aureo. Tourn. Cor.* Eaſtern Sneezwort, with hoary Tanſey-leaves, and a golden Flower.
14. Ptarmica *Orientalis, foliis tanaceti incanis, ſemifloſculis florum pallidè luteis. Tourn. Cor.* Eaſtern Sneezwort, with hoary Tanſey-leaves, whoſe Half-florets are of a pale yellow Colour.
15. Ptarmica *Orientalis, foliis tanaceti incanis, ſemifloſculis florum brevioribus. Tourn. Cor.* Eaſtern Sneezwort, with hoary Tanſey-leaves, whoſe Half-florets are very ſhort.
16. Ptarmica *Orientalis, ſantolinæ folio, radice repente.* Eaſtern Sneezwort, with a lavender-cotton Leaf, and a creeping Root.

17. Ptarmica *Orientalis, tanaceti folio & facie, flore minimo. Tourn. Cor.* Eaſtern Sneezwort, with the Leaf and Face of Tanſey, and the leaſt Flower.

18. Ptarmica *Orientalis incana, foliis pennatis, ſemifloſculis florum vix conſpicuis. Tourn. Cor.* Hoary Eaſtern Sneezwort, with winged Leaves, and the Half-florets ſcarcely diſcernable.

19. Ptarmica *Orientalis, foliis argenteis conjugatis. Tourn. Cor.* Eaſtern Sneezwort, with ſilvery conjugated Leaves.

The firſt of theſe Plants is very common upon Heaths, and in ſhady Places in divers Parts of *England*, and is rarely cultivated in Gardens. This is the Sort directed for Medicinal Uſe in the *College Diſpenſatory*.

The ſecond Sort is a Variety of the firſt, which was accidentally obtain'd: The Flowers of this Kind are very double, and generally produced in large Bunches; which, together with its long Continuance in flower, renders it worthy of a Place in every good Garden. This Sort propagates itſelf very faſt by its Roots, which ſpread very far under Ground; ſo that it ſhould not be planted too near other Plants, leſt it over-run and deſtroy them.

The beſt time to tranſplant theſe Roots is in *Autumn*, that they may take Root before *Winter*; ſo that they will be in no danger of ſuffering from Drought the *Spring* following; and will be capable of producing ſtronger Stalks, and a greater Quantity of Flowers.

This Plant always makes the beſt Appearance when its Roots are confined; becauſe, when they are ſuffered to ſpread, the Stalks come up thin and ſtraggling; and the greateſt Beauty of it is, to ſee it grow cloſe in large Tufts: for which Reaſon many Perſons chuſe to plant it in Pots fill'd with light ſandy Earth; in which, if they are duly watered in dry Weather, they will thrive exceedingly, and make a very handſome Appearance. It is alſo very proper to plant on ſuch Borders as are gravelly and poor, (on which few other things will thrive) where the Roots of this Plant will be confined, more than if planted in a better Soil, and they will flower very well.

The third and fourth Sorts are ſeldom preſerved in Flower-gardens, being Plants of little Beauty: Theſe may be propagated by parting their Roots, either in *Spring* or *Autumn*, and will grow upon almoſt any Soil, or in any Situation.

The fifth Sort was brought from the *Levant* by Monſ. *Tournefort*, but was known long before. Many of the old Botaniſts were of Opinion, that the Seeds of this Plant were the *Semen Santonicum* of the Shops; but it is now generally believed to be the Seeds of ſome other Plant of that Kind: But however, this Plant deſerves a Place in every good Garden, for the Variety of its Silver-colour'd Leaves, together with its long Continuance in flower.

It may be propagated by planting Cuttings during any of the *Summer* Months, upon a Bed of light freſh Earth, obſerving to water and ſhade them until they have taken Root, after which they will require no farther Care, but only to clear them from Weeds, until *September* following, when they ſhould be carefully taken up, preſerving a Ball of Earth to the Roots of each Plant, and planted in a warm dry Situation: and if it be on a poor gravelly or rubbiſhing Soil, they will endure the Cold better, and make much more beautiful Plants: This Sort ſeldom perfects Seeds in *England*.

All the laſt fourteen Sorts of *Ptarmica* are hardy enough to endure the Cold of our ordinary Winters in the open Air, provided they are planted in a dry lean Soil; for when they are in a moiſt rich Soil, they grow very luxuriant in the *Summer*, and are filled with Juice, which renders them leſs capable to reſiſt the Cold, than when they are more ſtunted and woody; and they make a much better Appearance, when they grow ſlowly, than if they were greatly encouraged in their Growth; becauſe they appear more hoary, and produce a greater Number of Flowers.

They may be all (except the ſixteenth Sort) propagated by Cuttings in the *Summer* Months, which ſhould be planted in a ſhady Border of freſh Earth, and muſt be conſtantly watered, until they have taken Root; after which Time they will require no farther Care, but to keep them clear from Weeds, until *Michaelmas*, when they ſhould be carefully taken up, and tranſplanted where they are deſigned to remain; which muſt be done ſo early in the *Autumn*, that they may have Time to get good Roots, before the Froſt comes on, otherwiſe they will be in Danger of ſuffering greatly. The ſixteenth Sort propagates itſelf by its creeping Roots very faſt, ſo requires to be confined; otherwiſe it will ſpread and intermix with whatever Plants grow near it. This is alſo a very hardy Plant, but being of humble Growth, makes no very good Figure in a Garden; ſo is ſeldom preſerved, but by thoſe Perſons who are curious in Botany, for the ſake of Variety.

Altho theſe Plants do not produce very beautiful Flowers, yet they may be diſpoſed in large Gardens, ſo as to make a very agreeable Diverſity; for their hoary Leaves of different Shapes, when intermixed with other hardy Plants of the ſame Growth, on ſmall Hillocks, will have a pretty Effect, and as they retain their Leaves all the Winter, ſo at that Seaſon they add to the Variety: and in *Summer* when their Flowers are produced, they alter the Proſpect ſo as to be very agreeable.

They are all of them low Plants: the talleſt and moſt ſhrubby of them ſeldom riſes above two Feet high, and the others not half ſo high, ſo that they ſhould not be mixed with larger Plants, becauſe thoſe would overbear and deſtroy them. When theſe Plants are well rooted, they require no other Culture, but to keep them clear from Weeds; for their Roots will abide many Years, provided they are not deſtroyed by very ſevere Froſts, which ſeldom happen in *England*.

PULEGIUM: [This Plant takes its Name of *Pulex* a *Flea*; becauſe, being burnt, it is ſaid to drive away Fleas] Penny-royal, *or* Pudding-Graſs.

The *Characters* are;

It hath a labiated Flower, conſiſting of one Leaf, whoſe Upper-lip (or Creſt) is intire; but the Lower-lip (or Beard) is divided into three Parts: Out of the Flower-cup riſes the Pointal, attended by four Embryo's, which afterwards become ſo many Seeds: To which may be added, that the Flowers grow in ſhort thick Whorles.

The *Species* are;

1. Pulegium *latifolium. C. B. P.* Common or Broad-leaf'd Penny-royal.

2. Pulegium *Hiſpanicum erectum, ſtaminibus florum extantibus.* Upright Spaniſh Penny-royal, whoſe Stamina ſtand out from the Flowers.

3. Pulegium *anguſtifolium. C. B. P.* Narrow-leaf'd Penny-royal.

4. Pulegium *anguſtifolium, flore albo. H. R. Par.* Narrow-leaf'd Penny-royal, with a white Flower.

The firſt of theſe Plants is very common on moiſt Heaths in divers Parts of *England*: This is the Sort recommended by the Phyſicians for Medicinal Uſe. But the ſecond Sort, although not a Native of *England*, hath obtain'd in the Gardens where Medicinal Plants are cultivated, ſo much as to have quite ſuperſeded the other in the Markets, for its upright Growth, early Flowering, and more beautiful Appearance: but whether it is equally good for Uſe, I ſhall leave to thoſe to whoſe Province it more immediately belongs to examine.

The third Sort is alſo recommended to be uſed in Medicine: This is not of *Engliſh* Growth, but is very hardy, and will thrive very well if planted on a moiſt Soil; as will alſo the fourth Sort, which is only a Variety of the third, from which it differs in nothing but the Colour of its Flowers.

All theſe Plants propagate themſelves very faſt by their Branches trailing upon the Ground, which emit Roots at every Joint, and faſten themſelves into the Earth, and ſend forth new Branches; ſo that no more is required in their Culture, than to cut off any of theſe rooted Branches, and plant them out in freſh Beds, allowing them at leaſt a Foot from Plant to Plant every way, that they may have Room to grow.

The beſt Time for this Work is in *September*, that the Plants may be rooted before *Winter*; for if the old Roots are permitted to remain ſo cloſe together, as they generally grow in the Compaſs of a Year, they are ſubject to rot in *Winter*: beſides, the young Plants will be much ſtronger, and produce a larger Crop the ſucceeding *Summer*, than if they were remov'd in the *Spring*: Theſe Plants do all love a moiſt ſtrong Soil, in which they will flouriſh exceedingly.

PULMONARIA, [ſo called of *Pulmones*, Lat. *the Lungs*, becauſe it is ſuppoſed to be a very good Medicament for the Lungs] Lung-wort.

The *Characters* are;

The Flower conſiſts of one Leaf, which is ſhaped like a Funnel, whoſe upper Part is cut into ſeveral Segments: From its fiſtulous Flower-cup, which is, for the moſt part, pentagonal, riſes *the Pointal, incompaſſed by four Embryo's, which afterwards become ſo many Seeds incloſed in the Flower-cup.*

The *Species are*;

1. PULMONARIA *vulgaris, maculoſo folio. Cluſ. Hiſt.* Common ſpotted Lungwort, *by ſome call'd* Sage of Jeruſalem, *and* Jeruſalem Cowſlip.

2. PULMONARIA *major, non maculoſa. J. B.* Greater Lungwort, without Spots.

3. PULMONARIA *foliis echii. Lob. Ic.* Lung-wort, with Leaves like Vipers Bugloſs.

4. PULMONARIA *maxima, foliis quaſi ſaccharo incruſtatis. Pluk. Phyt.* Greateſt Lung-wort, with Leaves very much ſpotted.

5. PULMONARIA *vulgaris latifolia, flore albo. Inſt. R. H.* Common broad-leaved Lung-wort, with a white Flower.

6. PULMONARIA *Alpina, foliis mollibus ſubrotundis, flore cœruleo. Inſt. R. H. Alpine* Lung-wort, with ſoft roundiſh Leaves, and a blue Flower.

7. PULMONARIA *anguſtifolia, cœruleo flore. J. B.* Narrow-leaved Lungwort, with a blue Flower.

8. PULMONARIA *Alpina, anguſto folio, Italica. Bocc. Muſ.* Narrow-leaved *Alpine* Lung-wort.

9. PULMONARIA *mitis, fragariæ odore. Bocc. Muſ.* Mild Lungwort ſmelling like Strawberries.

10. PULMONARIA *Cretica annua, calyce veſicario. Inſt. R. H.* Annual Lungwort of *Candy*, with a bladder Flower-cup.

11. PULMONARIA *viridi, ſubrotundo, non maculato folio. Bocc. Muſ.* Green Lungwort, with a roundiſh unſpotted Leaf.

12. PULMONARIA *Chia, echii folio verrucoſo, calyce veſicario, flore albo. Tourn. Cor.* Lungwort of the Iſland *Scio*, with a warted Vipers-bugloſs-leaf, a bladdered Flower-cup, and a white Flower.

13. PULMONARIA *Lesbia, echii folio verrucoſo, calyce veſicario, flore cœruleo. Tourn. Cor.* Lungwort of *Lesbos*, with a warted Vipers-bugloſs-leaf, a bladdered Flower-cup, and a blue Flower.

14. PULMONARIA *Orientalis, calyce veſicario, foliis echii, flore purpureo infundibuliformi. Tourn. Cor.* Eaſtern Lungwort, with a bladdered Flower-cup, a Vipers-bugloſs-leaf, and a purple funnel-ſhaped Flower.

15. PULMONARIA *Orientalis, calycc veſicario, foliis echii, flore albo infundibuliformi. Tourn. Cor.* Eaſtern Lungwort, with a bladdered Flower-cup, a Vipers-bugloſs-leaf, and a white funnel-ſhaped Flower.

The firſt Sort is uſed in Medicine as a vulnerary Herb, but is by many People preſerved in Gardens; as are alſo the three next Sorts for the Variety of their ſpotted Leaves, and pretty Bunches of blue Flowers.

Theſe Plants may be cultivated by parting of their Roots, which may be done either in the *Spring* or *Autumn*; but if the Ground be moiſt into which they are planted, it is better to be done in the *Spring*, otherwiſe the *Autumn* is the moſt preferable Seaſon, that the Plants may be well rooted before the dry Weather comes on in the *Spring*, which will cauſe them to flower much ſtronger.

The Soil in which they are planted ſhould not be rich, but rather a freſh, light, ſandy Ground, in which they will thrive much better than in a richer Soil, in which they are very ſubject to rot in *Winter*. The fourth Sort makes the beſt Appearance of all the Kinds, and is very hardy, will grow either in Sun or Shade, and, taking up little Room, is worthy of a Place in every good Garden for the ſake of Variety.

The fifth, ſixth, ſeventh, eighth, ninth, and eleventh Sorts are abiding Plants, which may be propagated by parting of their Roots: The beſt Time for doing of this is in *Autumn*, that they may be rooted before the Froſt comes on. They ſhould have a ſhady Situation, and a freſh undunged Soil, in which they will thrive better than a rich Soil.

The other Sorts are annual, ſo are propagated only by Seeds. The beſt time to ſow theſe is in *Autumn*, ſoon after they are ripe; for the Plants will reſiſt the Cold of our *Winters* very well, ſo will flower early the following *Summer*, and good Seeds may be obtained; whereas thoſe which are ſown in the *Spring* do ſometimes miſcarry. Theſe Seeds ſhould be ſown where they are deſigned to remain; for the Plants do not ſucceed very well when they are tranſplanted. When the Plants come up, they require no other Culture but to keep them clear from Weeds; and, where they are too cloſe to thin them. If theſe Plants are permitted to ſcatter their Seeds, the Plants will come up, and be better than when they are ſown. Theſe laſt eleven Plants are all preſerved by the Curious in Botany, but they have no greatB eauty, ſo are not often kept in other Gardens.

PULSATILLA; [ſo called of *Pulſando*, Lat. becauſe the Seeds of this Plant are blown, and fly away with the leaſt Wind] Paſque-flower.

The *Characters* are;

The Flower conſiſts of ſeveral Leaves, which are placed in a circular Order, and expand in the Form of a Roſe; *out of the Middle of which riſes a Pointal, beſet, for the moſt part, with Chives; which afterwards becomes a Fruit, in which the Seeds are gathered, as it were, into a little Head, each ending in a ſmall Hair: To which muſt be added, Some little Leaves incompaſſing the Pedicle below the Flower, as in the* Anemone; *from which the* Paſque-flower *differs, in the Seed ending in a Tail.*

The *Species* are;

1. PULSATILLA *folio craſſiore, & majore flore. C. B. P.* Paſque-flower, with thicker Leaves and a larger Flower.

2. PULSATILLA *flore violaceo duplici fimbriato. H. R. Par.* Paſque-flower, with a double-fringed violet-coloured Flower.

3. PULSATILLA *flore minore nigricante. C. B. P.* Paſque-flower, with a ſmaller darker Flower.

4. PULSATILLA *flore rubro obtuſo. C. B. P.* Red Paſque-flower.

5. PULSATILLA *flore albo. C. B. P.* White Paſque-flower.

6. PULSATILLA *lutea, Apii hortenſis folio. C. B. P.* Yellow Paſque-flower, with a Leaf of Garden-parſley.

7. PULSATILLA *lutea Alpina hiſpidior. C. B. P.* Yellow hairy Paſque-flower of the *Alps*.

8. PULSATILLA *folio tenuius inciſo, & flore minore, ſive paluſtris. C. B. P.* Marſh Paſque-flower, with fine cut Leaves, and a ſmaller Flower.

9. PULSATILLA *folio tenuius inciſo ſeu paluſtris, flore dilutiore. H. R. Par.* Marſh Paſque-flower, with a fine cut Leaf, and a paler Flower.

10. PULSATILLA *apii folio, vernalis, flore majore. C.B.P.* Spring Paſque-flower, with a ſmallage Leaf and a larger Flower.

11. PULSATILLA *apii folio, vernalis, flore minore. C.B.P.* Spring Paſque-flower, with a ſmallage Leaf, and a ſmaller Flower.

12. PULSATILLA *apii folio, autumnalis. C. B. P.* Smallage-leafed Paſque-flower, of the *Autumn*.

13. PULSATILLA *folio anemones ſecundæ, ſive ſubrotundo. C. B. P.* Paſque-flower, with a roundiſh Leaf.

14. PULSATILLA *Pyrenaica, flore albo duplici. H. R. Par.* Paſque-flower of the *Pyrenees*, with a double white Flower.

15. PULSATILLA *lutea, paſtinacæ ſylveſtris folio. C. B. P.* Yellow Paſque-flower, with a wild Parſnip Leaf.

16. PULSATILLA *Orientalis, tenuiſſime diviſa & villoſa, flore rubro. Tourn. Cor.* Eaſtern Paſque-flower, with a hairy, finely-divided Leaf, and a red Flower.

17. PULSATILLA *Africana, multifido flore, apii folio rigido. Raii Supp. African* Paſque-flower, with a multifid Flower, and a ſtiff ſmallage Leaf.

The firſt of theſe Plants is common in divers Parts of *England*; it grows in great Plenty on *Gogmagog-hills*, on the Left-hand of the Highway leading from *Cambridge* to *Haveril*, juſt on the Top of the Hill; alſo about *Hilderſham*, ſix Miles from *Cambridge*; and on *Bernack-heath*, not far from *Stamford*; and on *Southrop-common* adjoining thereto; alſo on mountainous and dry Paſtures juſt by *Leadſtone-hall*, near *Pontefract* in *Yorkſhire*. It flowers about the End of *March*, or Beginning of *April*.

The ſecond, third, fourth, fifth, ſixth and ſeventh Sorts are leſs common in *England*, being all of them Natives of other Countries, and are only to be met with in ſome curious Gardens in *England*, where they are cultivated for the Beauty of their Flowers.

Theſe Plants may be propagated by Seeds, which ſhould be ſown in Boxes or Pots filled with very light ſandy Earth; obſerving not to cover the Seeds too deep with Mould, which will prevent their riſing, for they require no more than juſt to be covered. Theſe Boxes ſhould be placed where they may have the Morning Sun until ten of the Clock, but muſt be ſcreen'd from it in the Heat of the Day: And if the Seaſon proves dry, the Earth ſhould be often refreſhed with

Water. The beſt Time for ſowing of theſe Seeds is in *July*, ſoon after they are ripe; for if they are kept till *Spring*, they ſeldom grow.

Theſe Boxes or Pots in which the Seeds are ſown ſhould remain in this ſhady Situation until the Beginning of *October*, when they ſhould be removed where they may enjoy the full Sun during the *Winter* Seaſon: About the Beginning of *March* the Plants will begin to appear, at which Time the Boxes ſhould be again removed where they may have only the Forenoon Sun; for if they are too much expoſed to the Heat, the young Plants will die away: They ſhould alſo be refreſhed with Water in dry Weather, which will greatly promote their Growth; and they muſt be carefully preſerv'd from Weeds, which, if ſuffered to grow amongſt them, will in a ſhort time deſtroy them.

When the Leaves of this Plant are intirely decay'd (which is commonly in *July*) you ſhould then take up all the Roots, which being nearly of the Colour of the Ground, will be difficult to find while ſmall; therefore you ſhould paſs the Earth through a fine Wire Sieve, which is the beſt Method to ſeparate the Roots from the Earth; (but notwithſtanding all poſſible Care taken, yet there will be many ſmall Roots left; ſo that the Earth ſhould either be put into the Boxes again, or ſpread upon a Bed of light Earth, to ſee what Plants will ariſe out of it the ſucceeding Year) The Roots being taken up, ſhould be immediately planted again on Beds of light, freſh, ſandy Earth, about three or four Inches aſunder, covering them about three Inches thick with the ſame light Earth: The *Spring* following moſt of theſe Plants will produce Flowers; but they will not be ſo large and fair as in the ſucceeding Years, when the Roots are larger.

They may alſo be propagated by parting of their Roots; the beſt Time for which is in *July* or *Auguſt*, when the Leaves are entirely decayed; for if they are removed while their Leaves remain freſh, the Roots do commonly rot: Theſe Roots being ſomewhat like thoſe of *Anemonies*, may be divided into ſeveral Tubers or Heads, but ſhould not be parted too ſmall, which will occaſion their Flowers to be very weak, and but few in Number: They muſt always be planted in a freſh undunged Soil, and ſhould have an open Situation; nor ſhould the Roots be tranſplanted oftener than every other Year, if you deſign to have them produce ſtrong Flowers; but the Earth upon the Surface of the Beds ſhould be refreſhed at leaſt once a Year, which will greatly encourage the Roots.

All the remaining Sorts (except the laſt) are very hardy Plants, which may be propagated by Seeds, in the ſame manner as directed before. Theſe ſhould have a pretty ſtrong loamy Soil, and a moiſt Situation, where they will thrive and produce their Flowers.

The laſt Sort is a tender Plant, which muſt be ſheltered in *Winter*, otherwiſe it will not live in this Climate. This is alſo propagated by Seeds, which ſhould be ſown, ſoon after it is ripe, in Boxes or Pots, which ſhould be placed in a ſhady Situation, and frequently refreſhed with Water. In *Autumn* the Plants will come up, when they ſhould be removed into a Situation where they may have more Sun, and in dry Weather they muſt be frequently watered. Towards the Middle or latter End of *October*, when the Nights begin to be cold, the Plants muſt be removed, and placed under a Hot-bed Frame, where they may be ſcreened from hard Froſts; but in mild Weather they ſhould have as much free Air as poſſible. In the following *Spring*, the Plants ſhould be tranſplanted each into a ſeparate Pot filled with freſh undunged Earth, and placed where they may enjoy the Morning Sun, where they ſhould remain all the Seaſon while they are expoſed; and in dry Weather they muſt be frequently watered; and every *Winter* they ſhould be ſheltered under a Frame, as before. With this Management the Plants will thrive and flower every Year, and ſometimes will produce good Seeds.

PUMPION; *vide* Pepo.

PUNICA: [This Plant takes its Name of its Punicean or red Colour, for its Flowers and Fruit are of a red Colour: It is called *Granatum*, of *Granis*, becauſe the Fruit has many Grains; or, as ſome ſuppoſe, of *Granata* or *Granada*, becauſe it grows in great Plenty in that Country.] The Pomegranate Tree.

The *Characters* are;

The Flower conſiſts of many Leaves, placed in a circular Order, which do expand in Form of a Roſe, whoſe Bell-ſhaped, multifid Flower-cup afterwards becomes a globular Fruit, having a thick, ſmooth, brittle Rind, and is divided into ſeveral Cells, which contain oblong, hard Seeds, ſurrounded with a ſoft Pulp.

The *Species* are;

1. PUNICA, *quæ malum Granatum fert. Cæſalp.* The Common Pomegranate.
2. PUNICA *fructu dulci. Tourn.* The Sweet Pomegranate.
3. PUNICA *ſylveſtris. Cord. Hiſt.* The Wild Pomegranate.
4. PUNICA *flore pleno majore. Tourn.* The Double flowered Pomegranate.
5. PUNICA *Americana nana, ſeu humillima. Tourn.* The American Dwarf Pomegranate.

The firſt of theſe Trees is now pretty common in the *Engliſh* Gardens, where formerly it was nurſed up in Caſes, and preſerved in Green-houſes with great Care (as was alſo the Double-flowering Kind); but they are both hardy enough to reſiſt the ſevereſt Cold of our Climate in the open Air; and if planted againſt warm Walls, in a good Situation, the firſt Sort will often produce Fruit, which, in warm Seaſons, will ripen tolerably well; but as theſe Fruits do not ripen till late in the *Autumn*, ſo they are ſeldom well-taſted in *England*; for which Reaſon the Sort with double Flowers is commonly preferred to it. The Sort with ſweet Fruit, as alſo the wild Sort, is leſs common in the *Engliſh* Gardens than the former two.

Theſe Plants may be eaſily propagated by laying down their Branches in the *Spring*, which in one Year's time will take good Root, and may then be tranſplanted where they are deſigned to remain. The beſt Seaſon for tranſplanting of theſe Trees is in *Spring*, juſt before they begin to ſhoot; they ſhould have a ſtrong, rich Soil, in which they flower much better and produce more Fruit, than if planted on a dry, poor Earth. But in order to obtain theſe in Plenty, there ſhould be Care taken in the pruning of the Trees; for want of which we often ſee theſe Trees very full of ſmall Shoots, but do not find many Flowers produced upon them; therefore I ſhall ſet down Directions for pruning of theſe Trees, ſo as to obtain a great Quantity of Flowers and Fruit.

The Flowers of this Tree are always produced at the Extremity of the Branches which were produced the ſame Year: This therefore directs, That all weak Branches of the former Year ſhould be cut out, and that the ſtronger ſhould be ſhorten'd in Proportion to their Strength, in order to obtain new Shoots in every Part of the Tree; Theſe Branches may be laid in againſt the Wall, about four or five Inches aſunder; for as their Leaves are ſmall, ſo there is not a Neceſſity of allowing them a greater Diſtance. The beſt Time for this Work is about *Michaelmas*, or a little later, according to the Mildneſs of the Seaſon; but if they are left until *Spring* before they are pruned, they ſeldom put out their Shoots ſo early; and the earlier they come out, the ſooner the Flowers will appear, which is of great Conſequence where Fruit is deſired. In *Summer* they will require no other Dreſſing but to cut off very vigorous Shoots which grow from the Wall, and do never produce Flowers (for they are the middling Shoots only which are fruitful); and when the Fruit is formed, the Branches on which they are, ſhould be faſtened to the Wall to ſupport them, otherwiſe the Weight of the Fruit, when grown large, will be apt to break them down.

Though, as I ſaid before, the Fruit of this Tree ſeldom arrives to any Perfection in this Country, ſo as to render it valuable; yet, for the Beauty of its ſcarlet Colour, together with the Variety of its Fruit, there ſhould be one Tree planted in every good Garden, ſince the Culture is not great which they require: The chief Care is to plant them upon a rich, ſtrong Soil, and in a warm Situation. Upon ſome Trees which had theſe Advantages, I have obſerved a great Quantity of Fruit which have arrived to their full Magnitude, but I cannot ſay they were well-flavoured; but, however, they made a very handſome Appearance upon the Trees.

The double-flowering Kind is much more eſteemed than the other in this Country, for the ſake of its large, beautiful, double Flowers, which are of a moſt beautiful ſcarlet Colour; and if the Trees are ſupply'd with Nouriſhment, will continue to produce Flowers for near three Months ſucceſſively, which renders it one of the moſt valuable flowering Trees yet known. This muſt be pruned and managed in the ſame Manner as hath been already directed for the Fruit-bearing Kind; but this Sort may be render'd more productive of its beautiful Flowers, by grafting it upon Stocks of the ſingle Kind, which will check the Luxuriancy of the Trees, and cauſe them to produce Flowers upon almoſt every Shoot: by which Method I have had a low Tree, which was planted in the open Air, extremely full of Flowers, which made a very fine Appearance.

The Dwarf Sort was brought into *Europe* from the warmeſt Parts of *America*, where the Inhabitants cultivate it in their Gardens for the Beauty of its Flowers, together with its continuing to produce Flowers and Fruit moſt part of the Year, and do ſeldom grow above three Feet high. The Fruit of this Kind is ſeldom much larger than a *Walnut*, and not very pleaſant to the Taſte; ſo that 'tis rather cultivated for Shew, than for the Sake of its Fruit.

This Plant may be propagated by Layers, in the ſame Manner as the former Sorts, but muſt be planted in Pots filled with rich Earth, and preſerved in a Stove, otherwiſe it is too tender to endure the Cold of our *Winters*; and in the *Summer*, when the Flowers begin to appear, if the Plants are expoſed to the open Air, the Buds will fall off, and never open; ſo that it ſhould ſeldom be removed into the open Air, but be conſtantly preſerved in the Stove with other Plants of the ſame Country; obſerving never to place them too near the Heat, which will cauſe them to produce long Shoots, but no Flowers will appear upon them; but rather let them have a moderate Warmth, in which they will thrive better than in a greater Heat.

I have heard of a Sort of *Pomegranate* with double-ſtriped Flowers, and have ſeen it mentioned in ſome foreign Catalogues, but have not ſeen the Plant growing; tho' I believe it may be eaſily procured from *Italy*.

PURSLAIN; *vide* Portulaca.

PYRACANTHA; *vide* Meſpilus.

PYROLA, Winter-green.

The *Characters* are;

It hath a Roſe-ſhaped Flower, conſiſting of ſeveral Leaves, which are placed circularly; out of whoſe Cup riſes the Pointal ending in a Proboſcis, which afterwards turns to a roundiſh Fruit, which is channelled, generally umbellated, and conſiſting of five Cells, which are commonly full of ſmall Seeds.

The *Species* are;

1. PYROLA *rotundifolia major. C. B. P.* Great round-leafed Winter-green.
2. PYROLA *rotundifolia minor. C. B. P.* Small round-leafed Winter-green.
3. PYROLA *folio mucronato ſerrato. C. B. P.* Winter-green, with a pointed Leaf, ſawed on the Edges.
4. PYROLA *fruteſcens, arbuti folio. C. B. P.* Shrubby Winter-green, with an Arbutus Leaf.

The firſt Sort grows wild in many Places in the North of *England*, on moſſy Moors and Heaths, as alſo in ſhady Woods, ſo that it is very difficult to preſerve in Gardens, in the Southern Parts.

The other three Sorts are Natives of the Hills, in *Germany*, *Italy* and *Hungary*. Theſe are all of them very difficult to cultivate in Gardens; for as they grow on very cold Hills, and in a moſſy mooriſh Soil, ſo when they are removed to a better Soil, and in a warmer Situation, they ſeldom continue long. The beſt time to tranſplant theſe Plants into Gardens, is about *Michaelmas*; when they ſhould be taken up with Balls of Earth to their Roots, and planted in a ſhady Situation, and on a moiſt undunged Soil, where they ſhould be frequently watered in dry Weather, otherwiſe they will not thrive. Some of theſe Plants may be planted in Pots, which ſhould be filled with Earth as nearly reſembling that in which they naturally grow as poſſible; and place them in a ſhady Situation, where, if they are conſtantly watered in dry Weather, they will thrive very well.

The Leaves of the firſt Sort are ſhaped like thoſe of the *Pear-tree*, from whence the Name was given to it; theſe Leaves are of a deep green Colour, and continue moſt part of the Year; but there is no great Beauty in their Flowers, tho' for Variety they are admitted into many curious Gardens.

The firſt Sort is ordered by the College of Phyſicians to be uſed in Medicine, and is generally brought over from *Switzerland*, amongſt other vulnerary Plants; amongſt which Claſs this Plant is ranged, and by ſome hath been greatly commended.

PYRUS; The Pear-tree.

The *Characters* are;

The Flower conſiſts of ſeveral Leaves, which are placed in a circular Order, and do expand in form of a Roſe; whoſe Flower-cup afterwards becomes a fleſhy Fruit, which is more produc'd towards the Footſtalk than the Apple, but is hollow'd like a Navel at the extreme Part: The Cells in which the Seeds are lodg'd, are ſeparated by ſoft Membranes, and the Seeds are oblong.

The *Species* are;

1. PYRUS *ſativa, fructu æſtivo parvo racemoſo odoratiſſimo. Tourn.* Petit Muſcat; *i. e.* Little Muſk Pear, *commonly call'd* The Supreme. This Fruit is commonly produced in large Cluſters: it is rather round than long; the Stalk ſhort; and, when ripe, the Skin is of a yellow Colour: the Juice is ſomewhat muſky, and, if gathered before it is too ripe, is an excellent *Pear:* This ripens at the Beginning of *July*, and will continue good but for a few Days.

2. PYRUS *ſativa, fructu æſtivo minimo odoratiſſimo. Tourn.* Poire de Chio, *i. e.* The Chio Pear, *commonly call'd* The Little Baſtard Muſk Pear. This is ſmaller than the former, but is in Shape pretty much like that: the Skin, when ripe, has a few Streaks of Red on the Side next the Sun, and the Fruit doth ſeldom hang in Cluſters as the former, but in other reſpects is nearly like it.

3. PYRUS *ſativa, fructu æſtivo parvo, è viridi albido. Tourn.* Poire Hativeau, *i. e.* The Haſting Pear, *commonly call'd* The Green Chiſſel. This is a larger *Pear* than either of the former, and is produced more toward the Pedicle: the Skin is thin, and of a whitiſh-green Colour when ripe; the Fleſh is melting, and, if not too ripe, of a ſugary Flavour. This ripens in the Middle of *July*.

4. PYRUS *ſativa, fructu æſtivo partim ſaturatè rubente, partim flaveſcente. Tourn.* Muſcadelles Rouges, *i. e.* The Red Muſcadelle. *It is alſo call'd* La Belliſſime, *i. e.* The Faireſt. This is a large early *Pear*, of great Beauty: the Skin is of a fine yellow Colour, when ripe, beautifully ſtriped with red; the Fleſh is melting, and has a rich Flavour, if gathered before it be too ripe. This generally produces two Crops of Fruit in a Year; the firſt is commonly ripe about the Middle of *July*, and the ſecond ripens in *September*; but this late Crop is ſeldom well-taſted.

5. PYRUS *ſativa, fructu æſtivo parvo flaveſcente moſchato. Tourn.* Petit Muſcat, *i. e.* The Little Muſcat. This is a ſmall *Pear*, rather round than long: the Skin is very thin, and, when ripe, of a yellowiſh Colour; the Fleſh is melting, and of a rich muſky Flavour, but will not keep long when ripe. This comes the Middle of *July*.

6. PYRUS *ſativa, fructu æſtivo oblongo, ferrugineo, carne tenera moſchata. Tourn.* Lady's Thigh, *now commonly call'd* Jargonelle. This is a very long *Pear*, of a pyramidal Shape, having a long Footſtalk: the Skin is pretty thick, of a Ruſſet-green Colour from the Sun, but towards the Sun it is inclined to an Iron Colour; the Fleſh is breaking, and has a rich muſky Flavour. Ripe the Middle of *July*. This is one of the beſt *Summer Pears* yet known, and is certainly what all the *French* Gardeners call the *Cuiſſe Madame*, as may be eaſily obſerved by their Deſcription of this *Pear:* but how that Name came to be applied to another Fruit in this Country, which is vaſtly inferior to it, I can not ſay.

7. PYRUS *ſativa, fructu oblongo, è viridi flaveſcente.* The *Windſor* Pear. This is an oblong Fruit, which is produced toward the Crown; but near the Stalk is drawn toward a Point: the Skin is ſmooth, and, when ripe, of a yellowiſh-green Colour; the Fleſh is very ſoft; and if it be permitted to hang but two or three Days after it is ripe, it grows mealy, and is good for nothing.

8. PYRUS *ſativa, fructu æſtivo oblongo, è viridi Albo.* The Jargonelle, *now commonly call'd* Cuiſſe Madame. This, I am apt to believe, is what the *French* Gardeners call the *Jargonelle*; which, as I before obſerved, is now, in *England*, given to another Fruit, much preferable to this; ſo that the two Names are changed: for the *Jargonelle* is always placed amongſt thoſe which the *French* call bad Fruit; and the *Cuiſſe Madame* is ſet down amongſt their beſt Fruit: which is certainly the Reverſe with us, as they are now nam'd. This *Pear* is ſomewhat like the *Windſor*, but is produced more toward the Crown, and is ſmaller toward the Stalk: the Skin is ſmooth, of a pale-green Colour; the Fleſh is apt to be mealy, if it ſtands to be ripe.

9. PYRUS *ſativa, fructu æſtivo globoſo ſeſſili moſchato, maculis nigris conſperſo. Tourn.* Orange Muſque, *i. e.* The Orange Muſk. This is a middle-ſized *Pear*, of a ſhort, globular form: the Skin is of a yellowiſh Colour, ſpotted with black; the Fleſh is muſky, but is very apt to be a little dry and choaky. It ripens the End of *July*.

10. Pyrus *ſativa, fructu æſtivo albido majori. Tourn.* Gros Blanquet, *i. e.* Great Blanket. This is alſo call'd *La Muſette d' Anjou*, i. e. The Bagpipe of *Anjou*. This is a large *Pear* approaching to a round form: the Skin is ſmooth, and of a pale-green Colour; the Fleſh is ſoft, and full of Juice, which hath a rich Flavour; the Stalk is ſhort, thick, and ſpotted; the Wood is ſlender; and the Leaf is very much like that of the Tree call'd the *Jargonelle*. This ripens the End of *July*.

11. Pyrus *ſativa, fructu æſtivo albido ſaccharato odoratiſſimo. Tourn.* The Blanquette, *or* Muſk Blanquette; The Little Blanket Pear. This *Pear* is much leſs than the former, and more pinch'd in near the Stalk, which is alſo ſhort, but ſlenderer than that of the former; the Skin is ſoft, and of a pale-green Colour: the Fleſh is tender, and full of a rich muſky Juice: The Wood of this Tree is much ſtronger than is that of the former, and the Shoots are commonly ſhorter. This ripens the End of *July*.

12. Pyrus *ſativa, fructu æſtivo albido, pediculo longo donato. Tourn.* Blanquette à longue queue, *i. e.* Long-ſtalk'd Blanket Pear. This *Pear* is in Shape ſomewhat like the former, but the Eye is larger, and more hollow'd at the Crown; towards the Stalk it is ſomewhat plumper, and a little crooked: the Skin is very ſmooth, white, and ſometimes toward the Sun is a little coloured; the Fleſh is between melting and breaking, and is full of a rich ſugary Juice. This ripens the Beginning of *Auguſt*.

13. Pyrus *ſativa, fructu æſtivo oblongo ruſeſcente ſaccharato. Tourn.* Poire ſans Peau, *i. e.* The Skinleſs Pear. It is alſo call'd *Fleur de Guigne*, i. e. Flower of *Guigne*; and *Rouſſellet hâtiff*, i. e. The Early Ruſſelet. This is a middle-ſized Fruit of a long Shape, and a reddiſh Colour, ſomewhat like the *Ruſſellet*: the Skin is extremely thin; the Fleſh is melting, and full of a rich ſugary Juice. This ripens the End of *July*.

14. Pyrus *ſativa, fructu æſtivo turbinato, carne tenera ſaccharata. Tourn.* Muſcat Robine, *i. e.* The Muſk Robin Pear. This is alſo call'd *Poire a la Reine*, i. e. The Queen's Pear; *Poire d' Ambre*, i. e. The Amber Pear; and *Pucelle de Xaintonge*, i. e. The Virgin of *Xaintonge*. This is a ſmall round *Pear*, of a yellowiſh Colour when ripe; the Fleſh is melting, and has a rich muſky Flavour. It is a great Bearer, and ripens the End of *July*.

15. Pyrus *ſativa, fructu æſtivo turbinato moſchato.* Le Bourdon Moſque, *i. e.* The Muſk Drone Pear. This a a middle-ſized round Fruit, whoſe Skin is of a yellowiſh Colour when ripe; the Fleſh is melting, and full of a high, muſky Juice: but it muſt not hang too long on the Tree, for it is ſubject to grow mealy in a ſhort time. This ripens the End of *July*.

16. Pyrus *ſativa, fructu æſtivo globoſo, ſeſſili, è viridi purpuraſcente ſaccharato odorato. Tourn.* Orange Verte, *i. e.* The Green Orange Pear. This *Pear* hath been the moſt common of all the Sorts in *France*, which was occaſion'd by the general Eſteem it was in ſome Years ſince. But this is a middle-ſiz'd round Fruit, of a greeniſh Colour, but the Side next the Sun changes to a purple Colour when ripe; the Fleſh is melting, and the Juice is ſugar'd, with a little Perfume; the Eye is very hollow, and the Stalk is ſhort. This ripens the Beginning of *Auguſt*.

17. Pyrus *ſativa, fructu æſtivo oblongo minori cinereo odorato. Tourn. Caſſolette.* This is ſo call'd from its being ſhaped like a Perfuming-pot. It is a long Fruit, in Shape like the *Jargonelle*, of an Aſh Colour; its Fleſh is melting, and full of a perfumed Juice, but is very apt to rot in the Middle ſo ſoon as ripe, otherwiſe it would be eſteem'd an excellent *Pear*. It is ripe the Beginning of *Auguſt*.

18. Pyrus *ſativa, fructu æſtivo turbinato, è viridi albido*; Poire Magdalené, *i. e.* The Magdalene Pear. This is a large round *Pear*, in Shape like a *Bergamot*: the Skin is green, and the Fleſh is melting; but it is very ſubject to rot upon the Tree, which renders it not near ſo valuable as ſome others. It ripens the End of *July*.

19. Pyrus *ſativa, fructu æſtivo globoſo, è viridi purpuraſcente. Tourn.* Gros Oignonet, *i. e.* The Great Onion Pear. It is alſo call'd *Amiré-roux*, i. e. Brown Admir'd; and *Roy d' Eſté*, i. e. King of Summer. This is a middle-ſiz'd, round *Pear*, of a browniſh Colour next the Sun; the Fleſh is melting, and the Juice is paſſably good. This ripens the End of *July*.

20. Pyrus *ſativa, fructu æſtivo globoſo ſeſſili, ex albido flaveſcente ſaccharato odorato. Tourn. Robine.* It is alſo call'd *Muſcat d' Aouſt*, i. e. The Auguſt Muſcat; *Poire d' Averat*, i. e. The Averat Pear; and *Poire Royale*, i. e. The Royal Pear. This is a roundiſh, flat *Pear*, in Shape very like a *Bergamot*: the Stalk is long, ſtraight, and a little ſpotted, and the Eye is a little hollowed; the Skin is ſmooth, and of a whitiſh yellow Colour; the Fleſh is breaking, but not hard; and its Juice is richly ſugar'd and perfum'd: It is a great Bearer, and is eſteem'd one of the beſt Summer *Pears* yet known. It ripens in *Auguſt*.

21. Pyrus *ſativa, fructu æſtivo globoſo ſeſſili odorato. Tourn.* Poire-roſe, *i. e.* The Roſe-Pear. This is a ſhort round Fruit, of a yellowiſh-green Colour, but a little inclining to red on the Side next the Sun: the Stalk is very long and ſlender; the fleſh is breaking, and the Juice is muſky. This ripens in *Auguſt*.

22. Pyrus *ſativa, fructu æſtivo globoſo albido ſaccharato. Tourn.* Poire du Pouchet. This is a large, round, whitiſh *Pear*, ſhaped ſomewhat like the *Beſideri*; the Fleſh is ſoft and tender, and the Juice is ſugary. This ripens the Middle of *Auguſt*.

23. Pyrus *ſativa, fructu æſtivo turbinato ſeſſili, ſaturatius rubente punctato. Tourn.* Poire de Parfum, *i. e.* The Perfum'd Pear. This is a middle-ſized, round Fruit, whoſe Skin is ſomewhat thick and rough, and of a deep-red Colour, ſpotted with brown; the Fleſh is melting, but dry, and has a perfumed Flavour. This ripens the Beginning of *Auguſt*.

24. Pyrus *ſativa, fructu æſtivo oblongo magno, partim rubro, partim albido, odorato. Tourn.* Bon-Chrêtien d'Eſté, *i. e.* The Summer Bon-Chrêtien, *or* Good Chriſtian. This is a large, oblong Fruit, whoſe Skin is ſmooth and thin: the Side next the Sun is of a beautiful red Colour, but the other Side is of a whitiſh-green: the Fleſh is between breaking and tender, and is very full of Juice, which is of a rich perfum'd Flavour. It ripens the End of *Auguſt*.

25. Pyrus *ſativa, fructu æſtivo globoſo, ex rubro albidoque flaveſcente ſaccharato odorato. Tourn. Salviati.* This *Pear* is pretty large, round, and flat, very much like the *Beſidery* in Shape, but not in Colour: the Stalk is very long and ſlender, and the Fruit is a little hollow'd both at the Eye and Stalk; the Colour is red and yellow next the Sun, but on the other Side is whitiſh: the Skin is rough; the Fleſh is tender, but a little ſoft; the Juice is ſugary, and perfum'd, ſomewhat like the *Robine*, but is not near ſo moiſt. This ripens the End of *Auguſt*.

26. Pyrus *ſativa, fructu æſtivo globoſo ſeſſili ruſeſcente odorato*; Caillot-roſat, *i. e.* Roſe-water Pear. This is a large round *Pear*, ſomewhat like the *Meſſire-Jean*, but rounder: the Stalk is very ſhort, and the Fruit is hollow'd like an *Apple* where the Stalk is produced: the Skin is rough, and of a brown Colour; the Fleſh is breaking, and the Juice is very ſweet. This ripens the End of *Auguſt*.

27. Pyrus *ſativa, fructu æſtivo longo, acerbitate ſtrangulationem minitante. Tourn.* Poire d' Etrangillon, *i. e.* The Choaky Pear. This is ſeldom preſerv'd in Gardens, ſo there needs no Deſcription of it.

28. Pyrus *ſativa, fructu æſtivo oblongo, è ferrugineo rubente, nonnunquam maculato.* Poire de Rouſſelet, *i. e.* The Ruſſelet Pear. This is a large oblong *Pear*: the Skin is brown, and of a dark-red Colour next the Sun; the Fleſh is tender and ſoft, without much Core; the Juice is agreeably perfum'd, if gather'd before it be too ripe: This produces larger Fruit on an Eſpalier than on Standard-trees. It ripens the end of *Auguſt*.

29. Pyrus *ſativa, fructu æſtivo ſubrotundo, partim rubro, partim flaveſcente, odorato.* Poire de Prince, *i. e.* The Prince's Pear. This is a ſmall roundiſh *Pear*, of a bright-red Colour next the Sun, but of a yellowiſh Colour on the oppoſite Side: the Fleſh is between breaking and melting; the Juice is very high-flavour'd; and it is a great Bearer. This ripens the End of *Auguſt*; but will keep a Fortnight good, which is what few Summer Fruits will do.

30. Pyrus *ſativa, fructu æſtivo globoſo viridi, in ore liqueſcente.* Gros Moüille-bouche, *i. e.* The great Mouth-water Pear. This is a large round *Pear*, with a ſmooth green Skin: the Stalk is ſhort and thick; the Fleſh is melting, and full of Juice, if gather'd before it be too ripe, otherwiſe it is apt to grow mealy. This ripens the Middle of *Auguſt*.

31. Pyrus *ſativa, fructu æſtivo rotundo ſeſſili ſaccharato, è viridi flaveſcente*; Bergamotte d' Eſté, *i. e.* Summer Bergamot. This is by ſome call'd the *Hamden's Bergamot*. It is a pretty large, round, flat *Pear*, of a greeniſh-yellow Colour, and hollow'd a little at both Ends like an *Apple*; the Fleſh is melting, and the Juice is highly perfum'd. This ripens the Middle of *Auguſt*.

32. Pyrus *ſativa, fructu autumnali ſeſſili ſaccharato odorato, è viridi flaveſcente, in ore liqueſcente. Tourn.* Bergamotte d'Automne, *i. e.* The Autumn Bergamot. This is a ſmaller *Pear* than the former, but is nearly of the ſame Shape: the Skin is of a yellowiſh Green, but changes to a a faint Red on the Side next the Sun; the Fleſh is melting,

and its Juice is richly perfum'd: It is a great Bearer, and ripens the Middle of *September*.

33. Pyrus *ſativa, fructu autumnali turbinato viridi, ſtriis ſanguineis diſtincta. Tourn.* Bergamot de Suiſſe, *i. e.* the Swiſs Bergamot. This *Pear* is ſomewhat rounder than either of the former: The Skin is tough, of a greeniſh Colour, ſtriped with red; the Fleſh is melting and full of Juice, but it is not ſo richly perfumed as either of the former. This ripens the End of *September*.

34. Pyrus *ſativa, fructu autumnali ſuaviſſimo, in ore liqueſcente. Tourn.* Beurre rouge, *i. e.* The Red Butter-Pear: It is call'd *l' Amboiſe*; and in *Normandy*, *Iſambert*; as alſo *Beurre gris*, i. e. The Grey Butter; and *Beurre vert*, i. e. The Green-Butter-Pear. All theſe different Names of *Beurre's* have been occaſion'd by the Difference of the Colours of the ſame ſort of *Pear*; which is either owing to the different Expoſure where they grew, or from the Stock: thoſe upon Quince Stocks being commonly of a browner Colour than thoſe which are upon free Stocks; whence ſome Perſons have ſuppos'd them to be different Fruits, though in reality they are the ſame. This is a large long Fruit, for the moſt part of a brown Colour; the Fleſh is very melting, and full of a rich ſugary Juice. It ripens the End of *September*; and, when gather'd from the Tree, is one of the very beſt Sort of *Pears* we have.

35. Pyrus *ſativa, fructu autumnali turbinato ſeſſili flaveſcente, & in ore liqueſcente. Tourn.* Le Dyenné, *i. e.* The Dean's Pear. It is alſo call'd by all the following Names; *Saint Michel*, i. e. *Saint Michael*; *Beurre blanc d' Automne*, i. e. The White Autumn Butter Pear; *Poire de Neige*, i. e. The Snow-Pear; *Bonne Ente*, i. e. a Good Graft; The *Carliſle* and *Valencia*. This is a large fair Fruit, in Shape ſomewhat like the *Grey Beurre*, but is ſhorter and rounder: the Skin is ſmooth, and, when ripe, changes to a yellowiſh Colour: the Fleſh is melting, and full of Juice; but it will not keep good a Week after it is gather'd, being very ſubject to grow mealy. This is a great Bearer, and ripens the End of *September*.

36. Pyrus *ſativa, fructu autumnali longo, viridique onorato, in ore liqueſcente. Tourn.* La Verte-longue, *i. e.* The Long Green Pear. It is alſo call'd *Moûille-bouche d' Automne*, i. e. The Autumn Mouth-water Pear. This is a long Fruit, which is very green when ripe: the Fleſh is melting, and very full of Juice; which, if it grows upon a dry warm Soil, and upon a free Stock, is very ſugary, otherwiſe it is but a very indifferent *Pear*. It ripens the Beginning of *October*.

37. Pyrus *ſativa, fructu autumnali tuberoſo ſeſſili, ſaccharato, carne dura. Tourn.* Meſſire Jean blanc et gris, *i. e.* The White and Grey Monſieur John. Theſe, although made two Sorts of Fruit by many Perſons, are indubitably the ſame; the Difference of their Colour proceeding from the different Soils and Situations where they grow, or the Stocks on which they are grafted. This *Pear*, when grafted on a free Stock, and planted on a middling Soil, neither too wet, nor over dry, is one of the beſt *Autumn* Pears yet known; but when it is grafted on a Quince-Stock, it is very apt to be ſtony; or if planted on a very dry Soil, is very apt to be ſmall and good for little, unleſs the Trees are watered in dry Seaſons: which has render'd it leſs eſteem'd by ſome Perſons, who have not conſider'd the Cauſe of their Hardneſs; for when it is rightly manag'd, there is not any Pear in the ſame Seaſon to be compar'd with it. This is a large roundiſh Fruit, the Skin is rough, and commonly of a brown Colour; the Fleſh is breaking, and very full of rich ſugar'd Juice. It ripens the Beginning of *October*, and will continue good moſt part of the Month.

38. Pyrus *ſativa, fructu autumnali, globoſo, ferrugineo, carne tenera, ſapidiſſima. Tourn.* Muſcat fleuri, *i. e.* The flower'd Muſcat. It is alſo call'd *Muſcat à longue queüe d Automne*, *i. e.* The Long-ſtalk'd Muſcat of the *Autumn*. This is an excellent Pear, of a middling Size, and round; the Skin is of a dark-red Colour; the Fleſh is very tender, and of a delicate Flavour. It ripens in the middle of *October*.

39. Pyrus *ſativa, fructu autumnali, globoſo, ferrugineo, carne viſcida. Tourn.* Poire de Vigne, *i. e.* The Vine Pear. This is a round Fruit, of a middling Size; the Skin is of a dark-red Colour; the Fleſh is very melting, and full of a clammy Juice; the Stalk is very long and ſlender. This Fruit ſhould be gather'd before it be full ripe, otherwiſe it grows mealy, and ſoon rots. It ripens in the Middle of *October*.

40. Pyrus *ſativa, fructu autumnali, oblongo, dilute ruffeſcente, ſaccharato, odoratiſſimo. Tourn.* Poire Rouſſeline, *i. e.* The Rouſſeline Pear. It is alſo call'd in *Touraine*, *Le Muſcat à longuequeüe de la fin d' Automne*, *i. e.* The long-ſtalk'd Muſcat of the End of *Autumn*. This is by ſome *Engliſh* Gardeners call'd the *Brute-bonne*; but that is a very different Fruit from this. It is ſhap'd ſomewhat like the *Rouſſelet*; but the Skin of this is ſmooth, and of a greeniſh Yellow from the Sun; but the Side next the Sun is of a deeper red Colour, with ſome Spots of Grey; the Fleſh is very tender and delicate; the Juice is very ſweet, with an agreeable Perfume. It ripens the Beginning of *October*, but muſt not be long kept, leſt it rot in the Middle.

41. Pyrus *ſativa, fructu autumnali, oblongo, majori, cinereo. Tourn.* Poire Pendar, *i. e.* The Knave's Pear. This is very like the *Caſſolette* Pear, but is ſomewhat larger; the Fleſh is fine and tender; the Juice is very much ſugar'd. It ripens in the End of *October*.

42. Pyrus *ſativa, fructu autumnali, turbinato, tuberoſo, viridi, ſaccharato, in ore liqueſcente. Tourn.* Sucré-vert, *i. e.* The Green Sugar-Pear. This Pear is ſhap'd like the *Winter Thorn*, but is ſmaller; the Skin is very ſmooth and green, the Fleſh is very buttery; the Juice is ſugar'd, and of an agreeable Flavour; but it is ſometimes ſubject to be ſtony in the Middle, eſpecially if grafted on a Quince Stock.

43. Pyrus *ſativa, fructu autumnali, tuberoſo, ſeſſili, e viridi flaveſcente, maculis nigris conſperſo, carne tenera ſaccharata. Tourn.* La Marquiſe, *i. e.* The Marquis's Pear. This is often of two different Shapes, according to the Nature of the Soil where they are planted; for when the Soil is dry, the Fruit very much reſembles a fine Blanquet; but when the Soil is very rich and moiſt, it grows much larger: It is a well-ſhap'd Pear, flat at the Top; the Eye is ſmall, and hollow'd; the Skin is of a greeniſh Yellow, a little inclining to Red on the Side next the Sun: If this Pear does not change yellow in ripening, it is ſeldom good; but if it does, the Fleſh will be tender and delicate, very full of Juice, which is ſugar'd. It ripens the End of *October*.

44. Pyrus *ſativa, fructu autumnali, oblongo, partim albido, partem ruffeſcente.* The Chatbrulé, *i. e.* The burnt Cat. It is alſo call'd *Pucelle de Xaintonge*, *i. e.* The Virgin of Xaintonge. This is a ſmall, oblong Pear, ſhap'd much like the *Martin Sec*, but differs from it in Colour; this being of a pale Colour on one ſide, but of a dark-brown on the other; the Skin is ſmooth; the Fleſh is tender, but dry, and, if kept a ſhort Time, is apt to grow mealy. It is in eating the latter End of *October*.

45. Pyrus *ſativa, fructu autumnali, globoſo, ſeſſili e albido flaveſcente.* Le Beſidéry. It is ſo call'd from *Heri*, which is a Foreſt in *Bretagne* between *Rennes* and *Nantes*, where this Pear was found. This is a middle-ſiz'd, round Pear, of a pale Green, inclining to a yellowiſh Colour; the Stalk is very long and ſlender; the Fleſh is dry, and but very indifferent for eating, but it bakes well. It ripens the End of *October*.

46. Pyrus *ſativa, fructu brumali, ſeſſili, e viridi flaveſcente, maculato, utrinque umbilicato, in ore liqueſcente. Tourn.* The Craſane, or Burgamot Craſane. It is alſo call'd *Beurre Plat*, *i. e.* the flat Butter Pear. This is a middle-ſiz'd, round Pear, hollow'd at both Ends like an Apple; the Stalk is very long and crooked; the Skin is rough, of a greeniſh yellow Colour when ripe, covered over with a Ruſſet Coat; the Fleſh is extremely tender, and buttery, and is full of a rich ſugar'd Juice. This is in eating the Beginning of *November*.

47. Pyrus *ſativa, fructu brumali turbinato ſeſſili, flaveſcente, ſaccharato, odorato, in ore liqueſcente. Tourn.* Lanſac ou la Dauphine, *i. e.* the Danſac or Dauphine Pear. This Pear is commonly about the ordinary ſize of a *Burgamot*, of a roundiſh Figure, flat towards the Head, but a little produc'd towards the Stalk; the Skin is ſmooth, and of a yellowiſh green Colour; the Fleſh is yellow, tender, and melting; the Juice is ſugar'd, and a little perfum'd; the Eye is very large, as is alſo the Flower, and the Stalk is long and ſtrait. When this Pear is upon a free Stock, and planted on a good Soil, it is one of the beſt Fruits of the Seaſon; but when it is on a Quince Stock, or upon a very dry Soil, the Fruit will be ſmall, ſtony, and worth little. It ripens in the Beginning of *November*.

48. Pyrus *ſativi, fructu brumali, oblongo, partim intenſe, partim dilute ferrugineo, ſaccharato, odorato. Tourn.* Martin-ſec, *i. e.* The Dry Martin. This is ſometimes call'd the *Dry Martin* of *Champaign*, to diſtinguiſh it from another *Dry Martin* of *Burgundy*. This Pear is almoſt like the *Rouſſelet* in ſhape and colour, which has occaſioned ſome Perſons to give it the Name of *Winter-Rouſſelet*. It is an oblong Pear, whoſe Skin is of a deep Ruſſet Colour on one ſide, but the other Side is inclining to a Red; the Fleſh is breaking and fine; the Juice is ſugared, with a little Perfume, and if grafted on a free Stock, is an excellent Pear; but if it be on a Quince Stock, it is very apt to be ſtony. It is in eating the middle of *November*; but if they were permitted to hang their full Time on the Tree, will keep good two Months.

49. Pyrus *ſativa, fructu brumali, magno ſeſſili, e cinereo flaveſcente. Tourn.* La Villaine d' Anjou, *i. e.* The Villain of Anjou. It is alſo call'd *Poire Tulipée, i. e.* The Tulip Pear; and *Bigarrade, i. e.* The Great Orange. This is a large round Pear, with a very long ſlender Stalk; the Skin is of a pale yellow Colour; the Fleſh is breaking, but not very full of Juice. This is in eating the Middle of *November.*

50. Pyrus *ſativa, fructu brumali, flaveſcente, odoratiſſimo, pediculo craſſiori. Tourn.* Poire de Gros queue, *i. e.* The Large ſtalk'd Pear. This is a large roundiſh Pear, with a yellow Skin; the Stalk is very thick, from whence it had the Name; the Fleſh is breaking, and dry, and has a very musky Flavour, but it is apt to be ſtony, eſpecially if it be planted in a dry Soil, or grafted on a Quince Stock, as are moſt of the perfum'd Pears.

51. Pyrus *ſativa, fructu brumali, turbinato, ruffeſcente, dorato.* L' Amadote, *i. e.* The Amadot Pear. This is a middle-ſiz'd Pear, ſomewhat long, but flat at the Top; the Skin is generally rough, and of a Ruſſet Colour; the Fleſh is dry, and high-flavour'd, if grafted on a free Stock. The Wood of this Tree is generally thorny, and is eſteem'd the beſt Sort of Pears for Stocks to graft the melting Pears upon, becauſe it gives them ſome of its fine musky Flavour. It is in eating the End of *November*, but will keep good ſix Weeks.

52. Pyrus *ſativa, fructu brumali, globoſo, dilute virente tuberoſo, punctato, in ore liqueſcente. Tourn.* Petit Oin, *i. e.* Little Lard Pear. It is alſo call'd *Bouvar* and *Rouſette d' Anjou, i. e.* The Ruſſet of Anjou, and *Amadont*, and *Marveille d' Hyver, i. e.* The Wonder of the Winter. This Pear is of the Size and Shape of the *Ambret* or *Leſchaſſerie*, but the Skin is of a clear green Colour, and a little ſpotted; the Stalk is pretty long, and ſlender; the Eye is large, and deeply hollow'd; the Fleſh is extremely fine, and melting; the Juice is much ſugar'd, and has an agreeable musky Flavour. It is in eating the End of *November* and moſt part of *December*, and is eſteem'd one of the beſt Fruits in that Seaſon.

53. Pyrus *ſativa, fructu brumali, longo e viridi albicante, in ore liqueſcente. Tourn.* Louiſe-bonne, *i. e.* The Good Lewis Pear. This Pear is ſhap'd ſomewhat like the *St. Germain*, or the *Autumn Vert longue*, but is not quite ſo much pointed; the Stalk is very ſhort, fleſhy, and ſomewhat bent, the Eye and the Flower is ſmall; the Skin is very ſmooth; the Colour is green, inclining to a white when ripe; the Fleſh is extremely tender, and full of Juice, which is very ſweet, eſpecially when it grows upon a dry Soil, otherwiſe it is apt to be very large and ill-taſted. It is in eating the latter End of *November* and the Beginning of *December*.

54. Pyrus *ſativa, fructu brumali, tuberoſo, e viridi flaveſcente, punctato, ſaccharato. Tourn.* Poire de Colmar, *i. e.* The Colmar Pear. It is alſo call'd *Poire Manne*, The Manna Pear; and *Bergamotte Tardive*, The late Burgamot. This Pear is ſomewhat like a *Boncretien* in Shape, but the Head is flat; the Eye is large, and deeply hollow'd; the Middle is larger than the Head, and is ſlop'd toward the Stalk, which is ſhort, large, and a little bent; the Skin is green, with a few yellowiſh Spots, but is ſometimes a little coloured on the Side next the Sun; the Fleſh is very tender, and the Juice is greatly ſugar'd. It is in eating the latter End of *November*, but will often keep good till *January*, and is eſteem'd one of the beſt Fruits of that Seaſon.

55. Pyrus *ſativa, fructu brumali, globoſo, Citriformi, flaveſcente, punctato, in ore liqueſcente, ſaccharato, odoratiſſimo. Tourn.* L'Eſchaſſerie. It is alſo call'd *Verte-longue d' Hyver, i. e.* The Winter-long green Pear; and *Beſideri-Landri, i. e.* The Landry Wilding. This Pear is ſhap'd like a Citron; the Skin is ſmooth, and of a green Colour, with ſome Spots while it hangs on the Tree, but as it ripens it becomes of a yellowiſh Colour; the Stalk is ſtrait and long; the Eye is ſmall, and not hollow'd; the Fleſh is melting, and buttery, the Juice is ſugar'd, with a little Perfume. It is in eating the latter End of *November*, and continues good till *Chriſtmas.*

56. Pyrus *ſativa, fructu brumali, longo e viridi flaveſcente, in ore liqueſcente, ſaccharato. Tourn.* La Virgolé, *or* La Virgoleuſe. It is alſo call'd *Bujaleuf, and Chambrette*; and *Poire de Glaſſe, i. e.* The Ice Pear in *Gaſcogny*; but it is call'd *Virgoule*, from a Village of that Name in the Neighbourhood of *St. Leonard* in *Limouſin*, where it was raiſed and ſent to *Paris* by the Marqueſs of *Chambret*. This Pear is large, long, and of a green Colour, inclining to yellow, as it ripens; the Stalk is ſhort, fleſhy, and a little bent; the Eye is of a middling Size, and a little hollow'd; the Skin is very ſmooth, and ſometimes a little colour'd towards the Sun; the Fleſh is melting, and full of a rich Juice. It is in eating the latter End of *November*, and will continue good till *January*, and is eſteem'd one of the beſt Fruits of the Seaſon; but the Tree is very apt to produce vigorous Shoots, and the Bloſſoms being generally produc'd at the extreme Part of the Shoot, where they are ſhorten'd, the Fruit will be intirely cut away, which is the Reaſon it is condemn'd as a bad Bearer; but when it is grafted on a free Stock, it ought to be allow'd at leaſt thirty Feet to ſpread; and if upon a Quince Stock it ſhould be allow'd upwards of twenty Feet, and the Branches train'd in againſt the Eſpalier or Wall, at full Length, in an horizontal Poſition, as they are produc'd. Where this Tree is thus treated, it will bear very plentifully.

57. Pyrus *ſativa, ſpinoſa fructu globoſo, ſeſſili, ferrugineo, in ore liqueſcente, ſaccharato, odoratiſſimo. Tourn.* Poire d' Ambrette. This is ſo call'd from its musky Flavour, which reſembles the Smell of the *Sweet Sultan Flower*, which is call'd *Ambrette* in *France*. This Pear is like the *Leſchaſſerie* in Shape, but is of a Ruſſet Colour; the Eye is larger, and more hollow'd; the Fleſh is melting, and the Juice is richly ſugar'd and perfum'd: the Seeds are large and black, and the Cells in which they are lodg'd are very large; the Wood is very thorny, eſpecially when grafted on free Stocks. The Fruit is in eating the latter End of *November*, and continues good till the latter End of *January*, and is eſteem'd a very good Fruit by moſt People.

58. Pyrus *ſativa, fructu brumali, magno, pyramidato, albido, in ore liqueſcenee, ſaccharato, odorato. Tourn.* Epine d' Hyver, *i. e.* Winter Thorn Pear. This is a large fine Pear, nearly of a pyramidal Figure; the Skin is ſmooth, and of a pale-green Colour, inclining to yellow as it ripens; the Stalk is ſhort and ſlender; the Fleſh is melting and buttery; the Juice is very ſweet, and in a dry Seaſon is highly perfum'd; but when it is planted on a moiſt Soil, or the Seaſon proves wet, it is very inſipid, ſo that it ſhould never be planted on a ſtrong Soil. It ripens the End of *November*, and will continue good two Months.

59. Pyrus *ſativa, fructu brumali, longo, e viridi flaveſcente, in ore liqueſcente. Tourn.* La Saint Germain, *i. e.* The Saint Germain Pear. It is alſo call'd *L' inconnue de la Fare, i. e.* The Unknown of La Fare, it being firſt diſcover'd upon the Banks of a River which is call'd by that Name, in the Pariſh of *St. Germain*. This is a large long Pear, of a yellowiſh green Colour when ripe; the Fleſh is melting, and very full of Juice, which in a dry Seaſon, or if planted on a warm, dry Soil, is very ſweet; but when it is planted on a moiſt Soil, the Juice is very apt to be harſh and auſtere, which renders it leſs eſteem'd by ſome Perſons, tho' in general it is greatly valu'd. This is in eating the End of *November*, but will many times continue good till *Chriſtmas.*

60. Pyrus *ſativa, fructu brumali, tuberoſo, ſubacido, flaveſcente, punctato. Tourn.* Saint Auguſtine. This is about the Size of a middling *Virgoulé* Pear, but is ſomewhat ſhorter, and ſlender near the Stalk, the Skin is of a fine Citron Colour, ſpotted with Red on the ſide next the Sun; the Fleſh is tender, but not buttery, and is pretty full of Juice, which is often a little ſharp, which to ſome Perſons is diſagreeable, but others value it on that Account. This is in eating in *December*, and will continue good two Months.

61. Pyrus *ſativa, fructu brumali, pyramidato, partim purpureo, punctis nigris conſperſo, partim flaveſcente. Tourn.* Bon-Chrêtien d'Eſpagne, *i. e.* The Spaniſh Bonchretien. This is a large Pear of a pyramidal Form, of a fine red or purple Colour on the ſide next the Sun, and full of ſmall black ſpots; the other ſide is of a pale yellow Colour; the Fleſh is breaking, and when it is on a light rich Soil, and grafted on a free Stock, its Juice is very ſweet. It ripens in the Beginning of *December*, and will continue good a Month or ſix Weeks. If this be grafted on a Quince Stock, it is very apt to be dry and Stony.

62. Pyrus *ſativa, fructu brumali, magno, oblongo, turbinato, ferrugineo, utrinque umbilicato. Tourn.* Poire de Livre, *i. e.* The Pound Pear. It is alſo called *Groſs Ratteau Gris*, i. e. the Grey Rak'd Pear; and *Poire d' Amour*, i. e. the Lovely Pear. This is a very large *Pear*, each of which does commonly weigh a Pound, or more; the Skin is rough, and of an obſcure red Colour on the Side next the Sun, but ſomewhat paler on the other Side; the Stalk is very ſhort, and the Eye is greatly hollow'd. This is not fit for eating, but bakes or ſtews exceedingly well, and is in Seaſon from *November* to *Chriſtmas.*

63. Pyrus *ſativa, fructu brumali, parvo, flaveſcente, maculis rubris conſperſo. Tourn.* Beſi de Caſſoy, *i. e.* the Wilding of *Caſſoy*, a Foreſt in *Brittany*, where it was diſcover'd, and paſſes under the Name of *Rouſſet d' Anjou.* It is alſo called *Petit Beurre d' Hyver*, i. e. Small Winter Butter Pear. This is a ſmall roundiſh *Pear*, of a yellowiſh Colour ſpotted with red; the Fleſh is melting, and the Juice is very rich.

It is in eating in *December* and *January*. This is a prodigious Bearer, and commonly produces its Fruit in large Cluſters, provided it be not too much pruned, for it generally produces its Bloſſom-buds at the Extremity of its Shoots, which, if ſhortened, the Fruit would be cut away. There was a Tree of this Kind in the Gardens of *Camden-houſe*, near *Kenſington*, which generally produced a great Quantity of Fruit.

64. Pyrus *ſativa, fructu brumali, turbinato, inequali ventre tumido, partim purpureo, partim flaveſcente. Tourn.* Ronville. It is alſo called *Hocrenaille* and *Martin-ſire*, i. e. the Lord Martin Pear. This *Pear* is about the Size and Shape of a large *Rouſſelet*; the Eye is of a middling Size, and hollowed a little; the Middle of the *Pear* is generally ſwelled more on one Side than of the other, but is equally extended towards the Stalk; the Skin is very ſmooth and ſoft, and is of a lively red Colour next the Sun; but on the other Side it changes yellow as it ripens; the Fleſh is breaking, and full of Juice, which is very ſweet, and a little perfumed; but if grafted on a Quince Stock, is very apt to be ſmall and ſtony.

65. Pyrus *ſativa, fructu brumali, Citriformi, flaveſcente, duro, Moſchato, odoratiſſimo. Tourn.* Citron d' Hyver, *i. e.* the Winter Citron Pear. It is alſo called the *Muſk Orange Pear* in ſome Places. This is a pretty large *Pear*, in Shape and Colour very like a Citron, from whence it had its Name; the Fleſh is hard and dry, and very ſubject to be ſtony, for which Reaſons it is not valuable as an eating *Pear*, but will bake very well. It is in Seaſon from *December* to *March*.

66. Pyrus *ſativa, fructu brumali, oblongo, e viridi flaveſcente, ſaccharato ſaporis auſteri. Tourn.* Roſſelet d' Hyver, *i. e.* the Winter Roſſelet. This is by ſome ſuppoſed to be the ſame *Pear* as is call'd the *Dry Martin*; but it is very different from that in ſeveral Particulars: The Colour of this is a greeniſh yellow; the Stalk is long and ſlender, and the Fleſh is buttery and melting, and generally full of Juice, which is very ſweet, but the Skin is apt to contain an auſtere Juice; ſo that if it be not pared, it is apt to be diſagreeable to many Perſons Palates. It is in eating in *January* and *February*.

67. Pyrus *ſativa, Pictavienſis, fructu brumali, globoſo, ſeſſili, ſaccharato, odorato. Tourn.* Poire Portail, *i. e.* the Gate Pear. This *Pear* was diſcover'd in the Province of *Poitou*, where it was ſo much eſteemed, that they preferred it to moſt other Fruit; though, in the Opinion of the moſt curious Judges, it does not deſerve the great Character which is given to it; for it rarely happens that it proves good for eating, being generally dry, ſtony and hard, unleſs in extraordinary Seaſons, and upon a very good Soil. This muſt always be grafted on a free Stock, and ſhould be planted on a light rich Soil, and in very dry Seaſons the Trees ſhould be water'd, otherwiſe the Fruit will be ſtony. It is in Seaſon from *January* to *March*, and bakes well.

68. Pyrus *ſativa, fructu brumali, magno, globoſo, flaveſcente, punctis rufis conſperſo. Tourn.* Franc-real. It is alſo called *Fin-Or d' Hyver*, i. e. the Golden End of Winter. This is a very large *Pear*, almoſt of a globular Figure; the Skin is yellow, ſpotted with red; the Stalk is ſhort, and the Wood of the Tree mealy: The Fleſh of this *Pear* is dry, and very apt to be ſtony; but it bakes exceeding well, and continues good from *January* till *March*.

69. Pyrus *ſativa, fructu brumali, turbinato, ſeſſili, ſubacido, flaveſcente, punctis aſperioribus conſperſo. Tourn.* Bergamote Bugi. It is alſo call'd *Bergamote de Paſque*, i. e. the Eaſter Bergamot. It is a large *Pear*, almoſt round, but is a little produced in Length towards the Stalk; the Eye is flat, and the Skin is green, having many rough Protuberances, like Spots, diſperſed all over, but as it ripens it becomes yellowiſh; the Fleſh is breaking, and in a good Seaſon the Juice is ſweet, but it muſt have a free Stock, a South-Eaſt Wall, and a good Soil, otherwiſe it is apt to be ſtony and auſtere. It is in eating from *February* till *April*.

70. Pyrus *ſativa, fructu brumali, magno, pyramidato, e flavo non nihil rubente. Tourn.* Bon-Chrêtien d' Hyver, *i. e.* the Winter Bon-chretien Pear. This *Pear* is very large and long, of a pyramidal Figure; the Skin is of a yellowiſh Colour, but the Side next the Sun inclines to a ſoft red; the Fleſh is tender and breaking, and is very full of rich ſugar'd Juice. This is eſteem'd in *France* one of the beſt *Winter Pears*, but in *England* it is ſeldom ſo good, tho' I am fully ſatisfied, if it were grafted on a free Stock, and planted in a good Soil, againſt a Wall expoſed to the South-Eaſt, and the Branches train'd at full Length, it might be rendered more acceptable than it is at preſent in *England*.

71. Pyrus *ſativa, fructu brumali, magno, cydoniæ facie, partim flavo, partim purpureo. Tourn.* Catillac, *or* Cadillac. This is a large Pear, ſhaped ſomewhat like a Quince; the Skin is for the moſt part of a yellow Colour, but changes to a deep red on the Side next the Sun, the Fleſh is hard, and the Juice auſtere, but it is one of the beſt Fruits for baking yet known, and being a plentiful Bearer deſerves a Place in every good Collection of Fruit. It will be good from *Chriſtmas* to *April*, or longer.

72. Pyrus *ſativa, fructu brumali, oblongo, flaveſcente, punctis rubris conſperſo.* La Paſtourelle. This *Pear* is of the Size and Shape of a fine *Rouſſelet*; the Stalk is ſhort and crooked; the Skin is ſomewhat rough, of a yellowiſh Colour, ſpotted with red: the Fleſh is tender and buttery; and when it grows on a dry Soil, the Juice is very ſweet; but on a wet Soil, or in moiſt Years, it is ſubject to have an auſtere Taſte. This *Pear* is in eating in *February* and *March*.

73. Pyrus *ſativa, fructu brumali, ſeſſili, partim flaveſcente, partim purpuraſcente. Tourn.* La Double Fleur, *i. e.* the Double-flowering Pear. This is ſo call'd, becauſe the Flowers have a double Range of Petals or Leaves. It is a large ſhort *Pear*; the Stalk is long and ſtrait; the Skin is very ſmooth, and of a yellowiſh Colour, but the Side next the Sun is commonly of a fine red or purple Colour. This is by ſome eſteem'd for eating, but it is generally too auſtere in this Country for that Purpoſe. It is the beſt *Pear* in the World for baking or Compoſts. It is good from *February* to *May*.

74. Pyrus *ſativa, fructu brumali, oblongo, partim flaveſcente, partim purpuraſcente.* Saint Martial. It is alſo call'd in ſome Places *Poire Angelique*, i. e. the Angelick Pear. This *Pear* is oblong, and has a very long Stalk; the Skin is ſmooth and yellowiſh, but on the Side next the Sun it turns to a purpliſh Colour; the Fleſh is tender and buttery, and the Juice is very ſweet. This is in eating in *February* and *March*.

75. Pyrus *ſativa, fructu brumali, oblongo, partim albido, partim purpureo, odorato, ſaccharato.* La Poire de Chaumontelle, *or* Beſi de Chaumontelle, *i. e.* the Wilding of Chaumontelle. This *Pear* is in Shape ſomewhat like the *Autumn Beurrè*, but is flatter at the Crown; the Skin is a little rough, of a pale green Colour, but turns to a purpliſh Colour next the Sun; the Fleſh is melting; the Juice is very rich, and a little perfum'd. It is in eating from *March* to *June*, and is eſteem'd the beſt late *Pear* yet known.

76. Pyrus *ſativa, fructu brumali, globoſo, ſeſſili, cinereo, maculis amplis obſcurioribus conſperſo. Tourn.* Carmelite. This is a middle-ſiz'd *Pear*, of a roundiſh Form; the Skin is of a grey Colour on one Side, but is inclining to a red on the other, having ſome broad Spots of a dark Colour all over; the Fleſh is commonly hard and dry, ſo that it is not very much eſteem'd. It is in Seaſon in *March*.

77. Pyrus *ſativa, fructu brumali maximo pyramidato, dilute virente.* The Union Pear; otherwiſe call'd Dr. *Uvdale's St. Germain.* This is a very large long *Pear*, of a deep green Colour, but the Side next the Sun doth ſometimes change to a red as it ripens. This is not fit for eating, but bakes very well; and being a great Bearer, and a very large Fruit, deſerves a Place in every good Collection. It is in Seaſon from *Chriſtmas* to *April*.

78. L'Aurate, *i. e.* the Aurate, is an excellent *Pear*: It ripens the Middle of *July*. It is a large *Pear*, ſhaped like the Muſcat, but is red on the Side next the Sun; this is at preſent very rare in *England*.

79. L'Eparque, ou Beau-Present, *i. e.* The fine Preſent; it is alſo called *Saint Samſon*. This is a large, long, green *Pear*, with a Bluſh of red next the Sun. The Fleſh is breaking; it hath a very long Stalk, and ripens the Beginning of *Auguſt*.

81. Le Rousselet de Reims. It is an excellent *Pear*. about the Size of the *Katharine*, or a little larger: It is ruſſet on the Side next the Sun, and of a browniſh yellow Colour on the other Side. It ripens the End of *Auguſt*.

81. L'Epine d'Ete, *i. e.* the Summer Thorn. This is a large long *Pear*, with a ſmooth green Skin: the Fleſh is melting, and ſomewhat perfumed. This is placed amongſt the good *Pears*. It ripens the Beginning of *September*.

82. La Poire d'oeuf, *i. e.* the Egg-Pear, ſo named from the Figure of its Fruit, which is ſhaped like an Egg. This is a large good *Pear* of a greeniſh Colour, ſtriped with Red on the Side next the Sun; the Fleſh is tender and half-buttery, and hath a high Flavour. This comes from *Germany*, where it is greatly eſteemed. It ripens in the Beginning of *September*.

83. L'ORANGE TULIPPE. The Orange Tulip, is a large round *Pear*, which is very red on the Side next the Sun, but greeniſh on the other Side; the Fleſh is half-breaking, and a little ſtony, but hath an agreeable Flavour: It ripens the Beginning of *September*.

84. LA MANSUETTE. This *Pear* greatly reſembles the *Winter Boncretien* in its Fruit, Wood and Leaves, but is ſmaller at the Eye. It is half-breaking, and hath an agreeable Flavour. It ripens the End of *September*. This *Pear* is greatly eſteemed in *Flanders*.

85. LE MUSCAT D'ALLEMAN, *i. e.* the German Muſcat. This is an excellent *Pear*, more long than round, of the Shape of the Winter-royal, but is leſs towards the Eye, and is more ruſſet, and of a red Colour next the Sun: It is buttery, melting, and a little musky. This is in eating in *March*, *April*, and ſometimes in *May*, if it keeps ſo long.

86. LA BERGAMOTTE DE HOLLANDE, *i. e.* the Hollands Bergamot. It is large and round, of the Shape of the ordinary Bergamot. The Colour is greeniſh, the Fleſh is half-buttery and tender; the Juice is highly flavour'd. This is a very good *Pear*, and will keep till *May*.

87. LA POIRE DE NAPLES, *i. e.* the Pear of Naples. This is a pretty large, long, greeniſh *Pear*; the Fleſh is half-breaking, the Juice is ſweet, and a little vinous. It is in eating in *March*. I am in Doubt whether this *Pear* is not in ſome Places taken for a *Saint Germain*; for there is a *Pear* in ſome Gardens very like the *St. Germain*, which will keep till *April*, and this *Pear* agrees with the Characters of that.

There are many other ſorts of *Pears* which are ſtill continu'd in ſome old Gardens; but as thoſe here mentioned are the beſt ſorts known at preſent, ſo it would be needleſs to enumerate a great Quantity of ordinary Fruit; ſince every one who intends to plant Fruits, will rather chuſe thoſe which are the moſt valu'd, the Expence and Trouble being the ſame for a bad ſort of Fruit as a good one. Indeed I have inſerted many more than are really worth planting, in order to pleaſe ſuch who are fond of a great Variety: but whoever hath a mind to make choice of ſuch only as are good, may eaſily diſtinguiſh them, by attending to the Account given of each ſort, and hereby every Perſon is at liberty to pleaſe himſelf; for it is not every one who prefers a *Beurre Pear*, tho' that is generally eſteem'd the very beſt in its proper Seaſon: There are ſome who admire the *Meſſire Jean*, for the Firmneſs of its Fleſh, which to others is a great Objection againſt it; ſo that as ſome eſteem the Breaking, and others, the melting *Pears*, I have diſtinguiſh'd them by their Deſcriptions in ſuch a Manner, that every one may make choice of the Kinds of Fruits which are agreeable to their Palates; and the different Seaſons in which each Kind is in eating, being exhibited, (allowing a little for the Difference of Seaſons, which are earlier ſome Years than others) it is not very difficult for a Perſon to make a Collection of good *Pears* to ſucceed each other throughout the Seaſon of theſe Fruits, both for Eating and Baking.

Pears are propagated by budding or grafting them upon Stocks of their own Kind, which are commonly call'd Free-Stocks, or upon Quince-Stocks, or White-Thorn, upon all which theſe Fruits will take; but the latter ſort of Stock is now ſeldom uſed, becauſe they rarely keep Pace in their Growth with the Fruit budded or grafted upon them; as alſo becauſe the Fruit upon ſuch Stocks are commonly drier, and more apt to be mealy, than when they are upon Pear-Stocks. Quince-Stocks are greatly uſed in the Nurſeries for all Sorts of *Pears* which are deſigned for Dwarfs or Walls, in order to check the Luxuriancy of their Growth, ſo that they may be kept within Compaſs better than upon Free-ſtocks. But againſt the general Uſe of theſe Stocks, for all ſorts of *Pears* indifferently, there are very great Objections: 1ſt, Becauſe ſome Sorts of *Pears* will not thrive upon theſe Stocks, but in two or three Years will decay, or at moſt will but juſt keep alive. 2dly, Moſt of the Sorts of hard breaking *Pears* are render'd ſtony, and good for little; ſo that whenever any of theſe Sorts are thus injudiciouſly rais'd, the Fruit, altho' the Kind be ever ſo good, is condemn'd as good for nothing, by ſuch as are not well acquainted with it, when the Fault is entirely owing to the Stock on which it was grafted. On the contrary, moſt melting buttery *Pears* are greatly improv'd by being upon Quince-Stocks, provided they are planted on a ſtrong Soil: but if the Ground be very dry and gravelly, no ſort of *Pear* will do well upon Quince-Stocks in ſuch Places.

Theſe general Directions being given, there is no Occaſion to repeat any Part of the Method in which theſe Stocks are rais'd, and the Fruits budded or grafted thereon; which has been already mentioned under the Article of Nurſeries.

The Diſtance which theſe Trees ſhould be planted either againſt Walls or Eſpaliers, muſt not be leſs than twenty-Feet: but if they are planted twenty-five Feet, it will be better; for if they have not Room to ſpread on each Side, it will be impoſſible to preſerve them in good Order, eſpecially thoſe on Free-Stocks; for the more theſe Trees are pruned, the more they will ſhoot; and, as I before ſaid, many ſorts of *Pears* do produce their Bloſſom-buds firſt at the Extremity of the former Year's Shoots, ſo that when they are ſhorten'd, the Fruit will be cut away; and this cannot be avoided, where the Trees have not Room allow'd in their firſt planting.

The Manner of preparing theſe Trees for Planting, is the ſame as hath been directed for other Fruit-trees, *viz.* To cut off all the ſmall Fibres from the Roots, and to ſhorten ſome of the longeſt Roots, and cut off all the bruiſed ones, or ſuch as ſhoot downright: This being done, you ſhould plant 'em in the Places intended at the before-mentioned Diſtance. The beſt Time to plant theſe Trees, (if upon a middling or dry Soil) is in *October*, leaving their Heads on 'till *Spring*, which ſhould be faſten'd to the Walls or Stakes, to prevent the Wind from diſturbing their Roots: and in the Beginning of *March* their Heads ſhould be cut off, in the Manner already directed for *Peaches* and other Fruit-trees; obſerving alſo to lay ſome Mulch upon the Surface of the Ground about their Roots when they are planted; as hath been ſeveral times already directed for other Trees.

The firſt *Summer* after planting, the Branches ſhould be trained to the Wall or Eſpalier (againſt which they are planted) in a horizontal Poſition, as they are produc'd without ſhortening of them; and the *Michaelmas* following theſe Shoots ſhould be ſhorten'd down to five or ſix Eyes, in order to obtain a ſufficient Quantity of Branches to furniſh the lower Part of the Wall or Eſpalier: But when this is done, the Shoots ought not to be ſhorten'd, unleſs where there is want of Branches to fill a Vacancy; for whenever the Shoots are ſtopp'd, it occaſions the Buds immediately below the Cut to ſend forth two or more Shoots, whereby there will be a Confuſion of Branches, and rarely any Fruit is produced with this Management.

The Diſtance which the Branches of *Pears* ſhould be train'd, muſt be proportion'd to the Size of their Fruit. Such Sorts whoſe Fruit are ſmall, may be allowed five or ſix Inches; but the larger Sorts muſt not be leſs than ſeven or eight Inches aſunder. If this be duly obſerv'd and the Branches carefully train'd horizontally as they are produced, there will be no occaſion for ſo much cutting as is commonly practis'd on theſe Trees, which, inſtead of checking their Growth, does, on the contraay, cauſe them to ſhoot the ſtronger.

It is very ſurprizing to read the tedious Methods which moſt of the Writers on Fruit-trees have directed for pruning of theſe Trees; for by their prolix and perplexed Methods, one would imagine they had endeavoured to render themſelves as unintelligible as poſſible: And this, I am ſure, may be affirmed, That it is next to impoſſible for a Learner ever to arrive at any tolerable Skill in Pruning, by the tedious and perplex'd Directions which are publiſh'd by Monſ. *Quintiney*, and thoſe who have copied from him; for theſe have all ſet out wrong in the Beginning, by allowing their Trees leſs than half the Diſtance at which they ſhould be planted; and then have preſcribed Rules to keep them within that Compaſs: which is what cannot be effected, where Perſons are deſirous of having Plenty of Fruit.

I ſhall therefore only lay down a few neceſſary Directions for the Pruning and Managing of theſe Trees; which ſhall be done in as few Words as poſſible, that a Learner may the more eaſily underſtand it; and which (together with proper Obſervations) will be ſufficient to inſtruct any Perſon in the right Management of them.

Pear-trees do generally produce their Bloſſom-buds firſt at the Extremity of the laſt Year's Shoots; ſo that if theſe are ſhorten'd, the Bloſſoms are cut off. But this is not all the Damage; for (as I before ſaid) this occaſions the Buds immediately below the Cut to put forth two or more Shoots, whereby the number of Branches will be increaſed, and the Tree crouded too much with Wood: Beſides, thoſe Buds which, by this Management, do produce Shoots, would have only produced *Curſons* and *Spurs*, upon which the Bloſſom-buds are produced, if the leading Branch had not been ſhorten'd; therefore theſe ſhould never be ſtopped, unleſs to furniſh Wood to fill a Vacancy.

It is not neceſſary to provide a new Supply of Wood in *Pear-trees*, as muſt be done for *Peaches*, *Nectarines*, &c. which only produce their Fruit upon young Wood; for *Pears* do produce their Fruit upon *Curſons* or *Spurs*, which are produced upon Branches which are three or four Years old, which *Curſons* do continue fruitful many Years; ſo that where theſe Trees have been ſkilfully managed, I have ſeen Branches which have been train'd horizontally, upwards of twenty Feet from the Trunk of the Tree, and have been fruitful their whole Length. And if we do but carefully obſerve the Branches of an healthful Standard Tree, which has been permitted to grow without pruning, we ſhall find many that are ten or twelve Years old, or more, which are very full of theſe *Curſons*, upon which is annually a good number of Fruit produced.

During the *Summer* Seaſon theſe Trees ſhould be often look'd over, to train in the Shoots, as they are produced, regularly, to the Wall or Eſpalier, and to diſplace fore-right and luxuriant Branches as they ſhoot out, whereby the Fruit will be equally expoſed to the Air and Sun, which will render them more beautiful, and better-taſted, than when they are ſhaded by the Branches; and by thus managing the Trees in *Summer*, they will always appear beautiful, and in *Winter* they will want but little pruning.

Where *Pear-trees* are thus regularly trained, without ſtopping of their Shoots, and have full Room for their Branches to extend on each Side, there will never be any occaſion for disbarking of the Branches, or cutting off the Roots, (as hath been directed by ſeveral Writers on Gardening); which Methods, however they may anſwer the Intention for the preſent, yet will certainly greatly injure the Trees; as muſt all violent Amputations, which ſhould ever be avoided, as much as poſſible, on Fruit-trees; and this, I am ſure, can never be wanted, where Trees have been rightly planted, and regularly trained, while young.

The Seaſon for pruning of theſe Trees, is any time after the Fruits are gathered, until the Beginning of *March*, but the ſooner it is done, after the Fruit is gathered, the better, for Reaſons already given for pruning of *Peach-trees*; though indeed, the deferring of theſe until *Spring*, where there are large Quantities of Trees to prune, is not ſo injurious to them, as to ſome more tender Fruits.

All the Sorts of *Summer Pears* will ripen very well, either on Standards, Dwarfs, or Eſpaliers; as will all the *Autumn Pears*, upon Dwarfs, or Eſpaliers: But where a Perſon is very curious in his Fruit, I would always adviſe the planting them againſt Eſpaliers, in which Method they take up but little Room in a Garden, and, if they are well managed, do appear very beautiful, and the Fruit is larger and better-taſted than thoſe produced on Dwarfs, as hath been already obſerved: But all the Sorts of *Winter Pears* muſt be planted againſt the Eaſt, South-Eaſt, or South-Weſt Walls, otherwiſe they ſeldom ripen well in *England*.

In the Gathering of *Pears*, great Regard ſhould be had to the Bud which is formed at the Bottom of the Footſtalk, for the next Year's Bloſſoms; which, by forcing off the *Pear* before it be mature, is, many times, ſpoiled; for during the Time the Fruit is growing, there is always a Bud formed by the Side of the Footſtalk upon the ſame Spur, for the next Year's Fruit; ſo that when the *Pears* are ripe, if they are gently turn'd upwards, the Footſtalk will readily part from the Spur, without injuring of the Bud.

The Seaſon for gathering all *Summer Pears* is juſt as they ripen; for none of theſe will remain good above a Day or two after they are taken from the Tree: nor will many of the *Autumn Pears* keep good above ten Days, or a Fortnight after they are gathered. But the *Winter* Fruits ſhould hang as long upon the Trees as the Seaſon will permit; for they muſt not receive the Froſt, which will cauſe them to rot, and render their Juices flat and ill-taſted; but if the Weather continues mild until the Middle of *October*, it will then be a good Seaſon for gathering them in, which muſt always be done in dry Weather, and when the Trees are perfectly dry.

In the doing of this, you ought carefully to avoid bruiſing them; therefore you ſhould have a broad flat Baſket to lay them in as they are gather'd; and when they are carry'd into the Store-room they ſhould be taken out ſingly, and each Sort laid up in a cloſe Heap, on a dry Place, in order to ſweat, where they may remain for eight or ten Days; during which time the Windows ſhould be open, to admit the Air, in order to carry off all the Moiſture which is perſpired from the Fruit: After this, the *Pears* ſhould be taken ſingly, and wiped dry with a Woollen Cloth, and then packed up in cloſe Baſkets, obſerving to put ſome ſweet Wheat-ſtraw in the Bottoms, and round the Sides of the Baſkets, to prevent their bruiſing againſt the Baſkets: You ſhould alſo obſerve to put but one Sort of Fruit into a Baſket, leſt, by their different Fermentations, they ſhould rot each other: But if you have enough of one Sort to fill a Baſket which holds two or three Buſhels, it will be ſtill better. After you have filled the Baſkets, you muſt cover them over with Wheat-ſtraw very cloſe, and faſten them down; then place theſe Baſkets in a cloſe Room, where they may be kept dry, and from Froſt; but the leſs Air is let into the Room, the better the Fruit will keep. It will be very neceſſary to fix a Label to each Baſket, denoting the Sort of Fruit therein contained; which will ſave the Trouble of opening them, whenever you want to know the Sorts of Fruit: Beſides, they ought not to be opened before their Seaſon to be eaten; for the oftner they are opened and expoſed to the Air, the worſe they will keep. I don't doubt but this will be objected to by many, who imagine Fruit cannot be laid too thin; for which Reaſon they make Shelves to diſpoſe them ſingly upon, and are very fond of admitting freſh Air whenever the Weather is mild, ſuppoſing it very neceſſary to preſerve the Fruit; but the contrary of this is found true, by thoſe Perſons who have large Stocks of Fruit laid up in their Store-houſes in *London*, which remain cloſely ſhut up for ſeveral Months, in the Manner before related; and when theſe are opened, the Fruit is always found plumper and ſounder than any of thoſe Fruits which were preſerved ſingly upon Shelves. For (as Mr. *Boyle* obſerves) the Air is the Cauſe of Putrefaction; and in order to prove this, that honourable Perſon put Fruits of ſeveral Kinds into Glaſſes where the Air was exhauſted, in which Places they remained ſound for ſeveral Months; but, upon being expoſed to the Air, did rot in a very ſhort time: Which plainly ſhews the Abſurdity of the common Method now uſed to preſerve Fruit.

QU

QUAMOCLIT, [it is an *Indian* Name] Bindweed.

The *Characters* are;

The Flower conſiſts of one Leaf, ſhaped like a Funnel, and divided at the Top into ſeveral Segments: From the Flower-cup riſes the Pointal, which afterwards becomes a roundiſh Fruit, incloſing ſeveral oblong Seeds.

We have but one *Species* of this Plant in *England*, which is,

QUAMOCLIT, *foliis tenuiter inciſis, & pennatis. Tourn.* Quamoclit, with very fine-cut winged Leaves, *commonly called*, in *Barbados*, Sweet William.

This Plant is very common in *Jamaica*, *Barbados*, and the *Caribbee* Iſlands, where it climbs upon Buſhes, Hedges, or whatever grows near it, and produces great Quantities of beautiful ſcarlet Flowers, almoſt of the Figure of a ſmall Convolvulus Flower: but the Tube being much larger, and the Seeds being of a different Figure from thoſe of the Convolvulus, Monſ. *Tournefort* hath ſeparated it from that Genus. The Seeds of this Plant are generally brought into *England* every *Spring* from the *Weſt-Indies*: They ſhould be ſown on a Hot-bed in *March*, and when the Plants are come up, they muſt be planted each into a ſmall Pot filled with light ſandy Earth, and plunged into a freſh Hot-bed, to bring the Plants forward. As the Plants advance in Height, ſo they ſhould be removed into larger Pots, and Sticks placed down by them, for 'em to climb upon: They muſt alſo be removed to a freſh Hot-bed, when the old one has loſt its Heat; and when the Plants are too high to be contain'd under Frames, they ſhould be remov'd into the Stove, where, if they are plung'd into a moderate Hot-bed of Tanners-bark, and not too much drawn, they will produce a great Quantity of beautiful ſcarlet Flowers, and ripen their Seeds very well: but if they are expoſed to the open Air, they ſeldom flower in this Country. This Plant continues but one Year, the Root periſhing ſoon after the Seeds are ripe.

QUERCUS, [ſo call'd of κέρχω, Gr. *to make rough*; becauſe of the Roughneſs of its Bark] The Oak-tree.

The *Characters* are;

It hath Male Flowers (or Katkins) which conſiſt of a great Number of ſmall ſlender Threads: The Embryo's, which are produced at remote Diſtances from theſe, on the ſame Tree, do afterwards become Acorns, which are produced in hard ſcaly Cups: To which may be added, the Leaves are ſinuated.

The *Species* are;

1. Quercus *latifolia. Park. Theat.* The Common Oak.

2. Quercus *latifolia mas, quæ brevi pediculo eſt. C. B. P.* Oak, with the Acorns on ſhort Footſtalks.

3. Quercus *latifolia, foliis ex albo eleganter variegatis.* The ſtriped Oak.

4. Quercus *latifolia perpetuo-virens. C. B. P.* The Broad-leaf'd Ever-green Oak.

5. Quercus *calyce echinato, glande majore. C. B. P.* Oak with large Acorns having prickly Cups.

6. Quercus *humilis, gallis binis, ternis aut pluribus ſimul junctis. C. B. P.* Dwarf-Oak, *vulgo.*

7. Quercus *Virginiana, rubris venis muricata. Pluk. Phyt.* The Virginian Scarlet Oak.

8. Quercus *caſtaneæ foliis, procera arbor Virginiana. Pluk. Phyt.* Virginian Oak, with Cheſnut Leaves.

9. Quercus *alba Virginiana. Park. Theat.* The White or Iron Oak of *Virginia.*

10. Quercus *Virginiana, ſalicis longiore folio, fructu minimo. Pluk. Amalth.* Virginian Willow-leaf'd Oak.

11. Quercus *pumilis, caſtaneæ folio, Virginienſis. Pluk. Almag.* The Chinquapin Oak.

12. Quercus *parva, ſive Phagus Græcorum, & Eſculus Plinii. C. B. P.* The ſweet Oak.

13. Quercus *calyce hiſpido, glande minore. C. B. P.* Oak with ſmall Acorns, having a prickly Cup.

14. Quercus *Burgundiaca, calyce hiſpido. C. B. P.* The *Burgundy* Oak, whoſe Acorns have prickly Cups.

15. Quercus *pedem vix ſuperans. C. B. P.* Dwarf Oak.

16. Quercus *foliis molli lanugine pubeſcentibus. C. B. P.* Oak with ſoft woolly Leaves.

17. Quercus *gallam exiguæ nucis magnitudine ferens. C. B. P.* Oak which bears ſmall Galls not larger than Nuts.

18. Quercus *foliis muricatis, non lanuginoſis, gallâ ſuperiori ſimili. C. B. P.* Oak with prickly Leaves, which are not woolly, bearing Galls like the former.

19. Quercus *foliis muricatis, minor. C. B. P.* Smaller Oak, with prickly Leaves.

20. Quercus *latifolia, magno fructu, calyce tuberculis obſito. Tourn. Cor.* Broad-leafed Oak, with large Acorns, whoſe Cups are beſet with Tubercles.

21. Quercus *Orientalis, glande cylindriformi, longo pediculo inſidente. Tourn Cor.* Eaſtern Oak, with cylindrical Acorns growing on long Footſtalks.

22. Quercus *Orientalis, caſtaneæ folio, glande recondita in cupula craſſa & ſquamoſa. Tourn. Cor.* Eaſtern Oak, with a cheſnut Leaf, whoſe Acorns are cloſely ſhut up in a thick ſcaly Cup.

23. Quercus *Orientalis anguſtifolia, glande minori, cupula crinita. Tourn. Cor.* Eaſtern Oak, with a narrow Leaf, and a ſmaller Acorn, whoſe Cup is hairy.

24. Quercus *Orientalis latifolia, glande maxima, cupula crinita. Tourn. Cor.* Eaſtern Oak, with a broad Leaf, and the largeſt Acorn, whoſe Cup is hairy.

25. Quercus *Orientalis latifolia, foliis ad coſtam pulchrè inciſis, glande maxima, cupula crinita. Tourn. Cor.* Eaſtern broad-leaved Oak, whoſe Leaves are finely cut to the Stalks, and a very large Acorn, whoſe Cup is hairy.

26. Quercus *Orientalis, folio ſubrotundo minori, glande magna ſtriata. Tourn. Cor.* Eaſtern Oak with a ſmaller roundiſh Leaf, and a large ſtriated Acorn.

27. Quercus *Orientalis, folio ſubrotundo, leviter inciſo, fructu minori cylindriformi. Tourn. Cor.* Eaſtern Oak, with a roundiſh Leaf, lightly cut in, and a ſmaller cylindrical Fruit.

28. Quercus, *an potius, Ilex Marilandica, folio longo anguſto ſalicis. Raii Hiſt.* The ſwamp willow Oak of *Maryland.*

29. Quercus *ſempervirens, foliis oblongis non ſinuatis. Baniſt.* Live Oak.

30. Quercus *(forte) Marilandica, folio trifido, ad ſaſſafras accedente. Raii Hiſt.* The black Oak of *Maryland.*

31. Quercus *folio non ſerrato, in ſummitate triangulo. Catesby Hiſt. Nat. Carolin.* The Water Oak.

32. Quercus *Carolinienſis, virentibus venis, muricata. Catesb. Hiſt. Nat. Carolin.* The White Oak of *Carolina.*

33. Quercus *humilior, ſalicis folio breviore. Catesb. Hiſt. Nat. Carolin.* Dwarf *Highland* willow Oak.

34. Quercus *eſculi diviſura, foliis amplioribus aculeatis. Pluk. Phyt.* Red Oak of *Maryland.*

35. Quercus *Mariana, oleæ folio, glande parvâ compreſſo, ad apiculam eleganter radiato. Pluk. Mantiſ.* Swamp *Spaniſh* Oak.

36. Quercus *Mariana, muricatis caſtaneæ foliis ſubtus villoſis. Pluk. Mant.* Champion cheſnut Oak of *Maryland.*

The two firſt Sorts are common in *England*; but the Sort whoſe Acorns grow on ſhort Footſtalks, is leſs frequent than the other. I have ſeen ſeveral Trees of that kind near *Dulwich* in *Surry*; but whether the Acorns of this Sort will produce Trees of the ſame Kind, I cannot determine. The Sort with ſtriped Leaves was obtain'd by Accident, but may be propagated by budding or grafting it upon the Common Oak: The Leaves of this are generally variegated with White in a moſt beautiful manner, and the Tree is eſteem'd a great Curioſity by ſuch as delight in variegated Plants.

The fourth Kind deſerves a Place in Wilderneſſes, amongſt other Sorts of Ever-green Trees, where it will make a beautiful Appearance; but the Timber is not near ſo good as that of the Common Sort.

The fifth Kind was originally brought into *England* from *Spain*, but is hardy enough to endure the Cold of our Winters very well: This is preſerved by ſuch as are curious in collecting the ſeveral Kinds of Trees.

The ſixth, ſeventh, eighth, ninth, tenth, and eleventh, have been brought from *America* (where there are a Variety of different *Oaks*) and are very hardy: Many of them are of quicker Growth than the Common Sort; and although their Timber is not ſo good, yet they deſerve a Place in large Wilderneſſes, where they will afford an agreeable Variety. As theſe Trees are propagated from Acorns; ſo thoſe Perſons who are deſirous to cultivate 'em, ſhould endeavour to obtain the Acorns freſh from *America*; which muſt be put up in Sand, to preſerve them during their Paſſage; and when they arrive in *England*, they ſhould be put into the Ground immediately, otherwiſe they will ſeldom grow.

Beſides the Sorts of *Oaks* here mentioned, there are divers others which are produced in ſeveral Parts of *Europe*, and differ in the Shape and Size of their Leaves and Fruit; but theſe are not to be found in any of our *Engliſh* Plantations at preſent: though, when I was at *Leyden* in *Holland*, in the Year 1727, I ſaw above forty Sorts of *Oaks*, in the curious Garden of the learned Dr. *Boerhaave*, near *Leyden*, moſt of which were in a very proſperous Condition, and had endured the Cold of that Climate two or three Years in the open Air; ſo that if theſe were procured in *England*, they would be equally as hardy as the Common Sort, and add to the Variety of our Plantations.

All the Sorts of *Oaks* are propagated from Acorns, which ſhould be ſown as ſoon as poſſible, when they are ripe; for if they are kept long out of the Ground, they ſeldom grow.

The Manner of ſowing theſe Acorns, (if deſigned for a ſmall Plantation, to be removed) is, to prepare a Bed or two of freſh Earth, neither too ſtrong and heavy, nor too light and dry; in theſe Beds you ſhould place the Acorns about two Inches aſunder, covering them about two Inches thick with the ſame freſh Earth; obſerving to leave none of them uncovered, to intice the Vermin, which may, in a ſhort time, deſtroy all the Seeds.

In the *Spring*, when the Plants begin to appear, you muſt carefully clear them from Weeds; and if the Seaſon proves dry, you ſhould refreſh them now and then with a little Water, which will greatly promote their Growth. In theſe Beds the Plants ſhould remain until the following *Spring*, (obſerving conſtantly to keep them clear from Weeds;) at which time you ſhould prepare a Spot of good freſh Earth, (in Size proportionable to the Quantity of Plants) which ſhould be well trenched and levell'd: Then, toward the Middle or Latter-end of *March*, you ſhould carefully take up the Plants, ſo as not to injure their Roots, and plant them out in Rows three Feet aſunder, and eighteen Inches diſtance Plant from Plant; obſerving never to ſuffer the Plants to abide long out of the Ground, becauſe their Roots would dry, and endanger the Growth of the Plants.

When they are planted, you ſhould lay a little Mulch upon the Surface of the Ground, near their Roots, to prevent the Earth from drying too faſt; and if the Seaſon be very dry, you ſhould give them a little Water, to ſettle the Earth to their Roots.

If theſe Things are carefully obſerved, there will not ſo many of the Plants miſcarry, as do generally in the common Method: For few Perſons conſider either the proper Method or Seaſon for removing theſe Trees; moſt People imagining it may be performed with equal Succeſs, any time after the Leaves begin to decay. But this is a very wrong Opinion; for, from ſeveral Experiments which I have made, in tranſplanting of theſe Trees in various Seaſons, I find they always ſucceed beſt, when they are tranſplanted juſt before they begin to ſhoot; at which Seaſon there will very few fail, provided they are removed with Care.

When the Plants have taken Root in this Nurſery, they will require little more Care than to keep 'em clear from Weeds, and dig the Ground between the Rows every *Spring*; in doing of which, you ſhould cut off ſuch Roots as extend very far from the Trunk of the Trees, which will render them better for tranſplanting again: You ſhould alſo prune off ſuch Side-branches as do extend themſelves very far, and would retard the upright Shoot: but you ſhould by no means cut off all the ſmall lateral Branches, ſome of which are abſolutely neceſſary to be left on, to detain the Sap for the Augmentation of the Trunk; for I have often obſerved, where Trees have been thus cloſely pruned, that their Heads have over-grown their Bodies, ſo that they have bent downward, and become crooked.

When theſe Trees have remained in the Nurſery three or four Years, they will then be large enough to tranſplant to the Places where they are to remain; for it is not proper to let them grow very large before they are planted out; becauſe theſe are very hazardous Trees to remove when old, or after they have taken deep Root.

The Seaſon for this Work is (as I ſaid) juſt before they begin to ſhoot, in the *Spring*; at which time, if they are carefully taken up, there will be little danger of their ſucceeding. When they are planted, the Surface of the Ground ſhould be mulched about their Roots, to prevent its drying too faſt: And if the Seaſon is very dry, they ſhould be watered, to ſettle the Earth to their Roots, which may be repeated two or three times in very dry Weather: but you muſt carefully avoid giving them too much Water, which is very injurious to theſe Trees, when newly removed.

You ſhould alſo ſtake them, to prevent their being ſhaken and diſturbed by the Winds, which would retard their rooting. In tranſplanting of theſe Trees, you ſhould by no means cut their Heads, which is too much practiſed: All that ſhould be done, muſt be only to cut off any bruiſed or ill-placed Branches, which ſhould be taken off cloſe to the Place where they are produced: But there can be no greater Injury done to theſe Trees, than to ſhorten their Shoots; for when the leading Bud (which is abſolutely neceſſary to draw and attract the Nouriſhment) is taken off, the Branch often decays entirely, or at leaſt down to the next vigorous Bud.

The Trees thus raiſed and managed, will (if planted in a proper Soil) grow to a conſiderable Magnitude, and are very proper for a Wilderneſs in large Gardens, or to plant in Clumps in Parks, *&c.* but if they are deſign'd for Timber, it is by much the better Method to ſow the Acorns in the Places where they are to remain; in order to which, you ſhould provide yourſelf in *Autumn* with a ſufficient Quantity of Acorns, which ſhould be always taken from ſtrait, upright, vigorous-growing Trees; theſe ſhould be gathered from under the Trees as ſoon as may be, after they are fallen, and, if poſſible, in a dry Time, laying them thin in ſome open Room to dry; after which, they may be put up in dry Sand, and preſerved in a dry Place until the End of *January*, when you ſhould prepare the Ground for planting them.

The Manner of doing this, when the Plantation is very large, ſhould be, to dig ſquare Spots about two Feet over, at every ten Feet Diſtance, into each of which you ſhould put four or five ſound Acorns, about two Inches deep, being careful to cover them all over, leſt, by leaving any of them above Ground, the Vermin ſhould be inticed, and thereby the greateſt Part of the Plantation ſhould be deſtroy'd. When the whole Plantation is finiſhed, it will be of great Service to ſtick into each Plot a few ſmall Buſhes, which will protect the Plants when they appear above Ground, from Cattle, and alſo from the Injury of Weather: And when the Plants are come up, the Weeds ſhould be carefully clean'd away from them during the growing Seaſon, which will greatly promote their Growth; and the following *Spring*, juſt before the Plants begin to ſhoot, you ſhould take them all up, except two of the moſt thriving out of each Plot, (which may be tranſplanted into another Place, if you have occaſion for them:) but in doing of this, you ſhould be very careful not to diſturb the Roots of the remaining Plants: And it will be very neceſſary to renew the Buſhes about them where they are left, to protect them from Cattle, and the following *Summer* they ſhould be kept clear from Weeds.

In this manner they may remain three or four Years, (obſerving every *Spring* to dig and looſen the Earth about their Roots, which will be of great Service to them;) by which time you will eaſily judge which of the two Plants left in each Plot, is likely to make the beſt Tree, ſo that the other ſhould now be taken away, being very careful how you dig near the remaining Plants, leſt you ſhould injure their Roots: And if at this time you find any of them with very crooked, unſightly Stems, you may cut them down near the Surface of the Ground; and if their Roots are ſtrong, they will ſend forth ſtrait vigorous Shoots the following *Summer*, and make kindly handſome Plants.

When theſe Plants are advanced out of the Reach of Cattle, they will require but little more Care, except to prune off any ſtrong lateral Branches, where they are produced, in order to ſtrengthen the leading Shoot: but you ſhould by no means be too buſy in pruning theſe Trees, which will greatly retard their Growth. The Expence of ſuch Plantations is but ſmall, eſpecially where Labour is cheap; and the Profits which muſt ariſe from them, to the Succeſſors of thoſe who are ſo beneficent to their Poſterity, as to lay out a ſmall Share of their Fortune this way, will be very great: but as this has been fully treated of by the eminent Mr. *Evelyn*, ſo I ſhall not repeat it in this Place, but refer the Curious to his valuable Treatiſe of *Foreſt Trees*, where they will find enough ſaid, to encourage all Gentlemen of Eſtates, to lay out ſome of their preſent Fortune, to inrich their Families.

The twelfth, thirteenth, fourteenth, fifteenth, ſixteenth, ſeventeenth, eighteenth and nineteenth Sorts grow on the Hills in *Spain*, *Portugal*, *Germany*, and *Hungary*, from whence their Acorns may be obtained; which ſhould be ſown after the manner above directed; for altho' ſome of theſe Sorts naturally grow in Countries which are warmer than *England*, yet they will thrive as well as the common Sort in the open Air.

The next eight Sorts were diſcovered by Dr. *Tournefort* in the *Levant*, and ſome of theſe Sorts have been introduced into the *Engliſh* Gardens, where they thrive, and are as hardy as the common Sort.

The other nine Sorts are Natives of the cold Parts of *America*: moſt of them grow in *New England*, *Virginia* and *Maryland*, and other Places on the Continent, where the Woods have not been cleared. Theſe moſt of them delight in a Soil which is moiſt: for in dry Land they do not thrive well. They may be propagated by ſowing of their Acorns, after the ſame manner as the common Sort; but as theſe muſt be procured from *America*, (there being none of theſe Trees in *England* which produce Fruit at preſent) ſo they ſhould be put up in Sand, ſoon after they are ripe, and forwarded to *England*: for all Sorts of Acorns are ſubject to periſh, if they are not planted, or put up in Sand, in a very little Time after they fall from the Trees: ſo that it is more difficult to tranſport theſe Seeds, than thoſe of moſt other Plants.

When the Acorns arrive, they ſhould be planted as ſoon as poſſible; for if they are good, it will be near two Months from the Time of ſowing to the appearing of the Plants; and the earlier theſe come up in the Spring, the more Time they will have to get Strength before Winter, ſo will be in leſs Danger of ſuffering from the Cold. For while theſe Plants are very young and tender, they are often injured by ſevere Froſt; tho', when they have obtained Strength, they will endure the greateſt Cold of our Winters extremely well. Therefore, if the firſt Winter after the Plants come up from Acorns, ſhould prove very ſevere, it will be proper to ſcreen them from the Froſt; which may be done by laying ſome Branches of Oak, with the decayed Leaves on them, or ſome dry Fern or Furze over them, which will prevent the Froſt from penetrating very deep in the Ground; and theſe lying hollow, will admit a ſufficient Quantity of Air to the Plants, to prevent their taking the Mould, which is very injurious to them. After the firſt Year, theſe Sorts may be treated in the ſame manner as the common Oak, by tranſplanting them into Nurſeries, or the Places where they are to remain.

The twenty-five laſt mention'd Sorts of Oak are all o them inferior to the common Sort of our own Growth, in regard to their Timber, ſo ſhould not be cultivated for tha Purpoſe: but as ſome of them have large beautiful Leaves, ſo they make an agreeable Variety, when mixed with othe Trees in Gardens, and other ſmall Plantations. And a ſome of theſe Sorts are of very humble Growth, ſo the may be planted for Underwood, in ſuch Plantations wher they will have a good Effect; and many of the Sorts conti nue green throughout the Year, which renders them mor valuable; and thoſe Sorts whoſe Leaves are downy under neath, make a moſt agreeable Proſpect, when viewed at Diſtance; for as the Wind turns up the Leaves, ſo they ap pear to be covered over with Silver; and theſe Trees riſe t a great Height. There is one of the ſixteenth Sort growing a *Ragnal* near *Tucksford* in *Nottinghamſhire*, which is upwar

o

of forty Feet high, and produces a great Number of Acorns almoſt every Year, from whence ſeveral Plants have been raiſed. But theſe Acorns being ſo cloſely ſhut up in their Cups, do not ripen well in a cold wet Seaſon.

QUICK, delights in a Ground that is more dry than wet, (for watery Places it abhors.) Plant *Quick* in the following Manner:

Let the firſt Rows of Sets be placed in a Trench of about half a Foot deep, even with the Top of the Ditch, in ſomewhat a ſloping or inclining Poſture; then having rais'd the Bank near a Foot upon them, plant another Row, ſo as their Tops may juſt peep out over the Middle of the Spaces of the firſt Row: Theſe cover again to the Height and Thickneſs of the other, and place a third Rank oppoſite to the firſt, and then finiſh the Bank to its intended Height.

The Diſtances of the Plants ſhould not be above one Foot; and the Seaſon to do the Work in, may be from the Beginning of *February* 'till the End of *March*; or elſe from *September* to the Beginning of *December*.

When this is finiſh'd, you muſt guard both the Top of the Bank, and the outmoſt Verge of the Ditch with a ſufficient dry Hedge interwoven from Stake to Stake into the Earth, (which commonly they do on the Bank) to ſecure the *Quick* from the Spoil of Cattle.

You muſt alſo be careful to repair ſuch as decay, the following *Spring*, by ſupplying the dead, and trimming the reſt; and after three Years Growth, intermix ſome Timber-trees amongſt them, ſuch as *Oak*, *Aſh*, *Beech*, *Maple*, *Fruit*, or the like; which being drawn young out of the Nurſeries, may be very eaſily inſerted.

Some indeed object againſt ſcattering theſe Maſts and Keys amongſt Fences; which being grown, over-top the Hedge that grows under it, and may prejudice it with their Shade and Drip: But this may be prevented by planting *Hollies* (which are Proof againſt theſe Impediments) in the Line or Trench where you would raiſe Standards, as far as they uſually ſpread in many Years, and which, if placed at good Diſtances, how cloſe ſoever to the Stem, would (beſide their ſtout Defence) prove a great Decoration to large and ample Incloſures.

In *February* or *October*, with a ſharp Hand-bill, cut away all ſuperfluous Sprays and Straglers; then ſearch out the principal Stems, and with a keen and light Hatchet cut them ſlantwiſe cloſe to the Ground hardly three-quarters through, or rather ſo far only as 'till you can make them comply handſomely, leſt you rift the Stem, and ſo lay it from you ſloping as you go, folding in the leſſer Branches which ſpring from them; and ever within five or ſix Feet Diſtance, where you find an upright Set, (cutting off only the Top to the Height of your intended Hedge) let it ſtand as a Stake, to fortify your Work, and to receive the twining of thoſe Branches about it.

Laſtly: At the Top, (which ſhould be about five Feet above Ground) take the longeſt, moſt ſlender, and flexible Twigs which you reſerv'd, and (being cut as the former, where Need requires) bind in the Extremities of all the reſt; and thus your Work is finiſhed.

This being done very cloſe and thick, makes an impregnable Hedge in few Years; for it may be repeated as you ſee occaſion; and what you ſo cut away, will help to make your dry Hedges for your young Plantations, or will be uſeful for the Oven, and make good Bavin, eſpecially the extravagant Side-branches, which will ſpring upright, 'till the newly-wounded are healed.

There are ſome who would have no Stakes cut from the Trees, ſave here and there one, ſo as to leave half the Head naked, and the other ſtanding: but the over-hanging Boughs will kill what is under them, and ruin the Tree, ſo pernicious is this Half-topping.

There is nothing more prejudicial to under-growing young Trees, than, when newly trimmed and pruned, to have their (as yet raw) Wounds poiſon'd with continual Dripping.

For Stakes in this Work, *Oak* is to be prefer'd, though ſome will uſe *Alder*, but it is not good, or the *Bl[illegible]k-thorn*, *Crab-tree*: In Mooriſh Ground, *Withy*, *Aſh*, *Maple*, *Hazle*, (which ſome make Hedges of; but being ſubject to the browſing of Cattle, when the young Shoots appear, it does better in Copſes) theſe not laſting, ſhould be yet drove well in at every Yard of Interval, both before and after they are bound, 'till they have taken the hard Earth, and are very faſt; and even your plaſhed Hedges need ſome ſmall Thorns to be laid over, to protect the Shoots from Cattle and Sheep 'till they are ſomewhat fortify'd: and the doubler the Winding is lodg'd the better, which ſhould be beaten and forced down together with the Stakes, as equally as may be.

Note, That in ſloping your Windings, if it be too low done (as very uſually) it frequently mortifies the Tops; therefore it ought to be ſo bent, as it may not impede the mounting of the Sap.

If the *Plaſh* be of an extraordinary Age, wind it at the nether Boughs all together; and cutting the Sets, as directed, permit it rather to hang downwards a little, than to riſe too forward; and then twiſt the Branches into the Work, leaving a Set free and unconſtrain'd at every Yard-ſpace, beſides ſuch as will ſerve for Stakes, abated to about five Feet Length, (which is a competent Stature for a Hedge) and ſo let it ſtand.

One ſhall often find in this Work, eſpecially in old neglected Hedges, ſome great Trees or Stubs, that commonly make Gaps for Cattle; ſuch ſhould be cut ſo near the Earth, as, 'till you can lay them athwart, that the top of one may reſt on the Root or Stub of the other as far as they extend, ſtopping the Cavities with its Boughs and Branches: And thus a Hedge, which ſeems to conſiſt of nothing but ſcrubby Trees and Stumps, may be reduced to a tolerable Fence: but in caſe it be ſuperanuated, it is adviſeable to ſtub all up, and quite to renew it.

Thomas Franklin, Eſq; has given the following Account of his Method of planting *Quick*.

He firſt ſet out the Ground for Ditches and *Quick* ten Feet in Breadth; he ſubdivided that, by marking out two Feet and a half on each Side (more or leſs at Pleaſure) for the Ditches, leaving five in the Middle between them; then digging up two Feet in the midſt of that five Feet, he planted the Sets in; which, although it required more Labour and Charge, he ſays, he ſoon found it repaid the Coſt: This done, he began to dig the Foſſes, and to ſet up one Row of Turfs on the Outſide of the ſaid five Feet: namely, one Row on each Side thereof, the green Side outmoſt, a little reclining, ſo as the Graſs might grow.

After this, returning to the Place he began at, he order'd one of the Men to dig a Spit of the under Turf-mould, and lay it between the Turfs placed edgewiſe, as before deſcribed, upon the two Feet which was purpoſely dug in the Middle, and prepared for the Sets, which the Planter ſets with two *Quicks* upon the Surface of the Earth almoſt upright, whilſt another Workman laid the Mould forwards about twelve Inches, and then ſet two more, and ſo continued.

This being finiſhed, he order'd another Row of Turfs to be placed on each Side upon the Top of the former, and fill'd the Vacancy between the Sets and Turfs as high as their Tops, always leaving the Middle, where the Sets were planted, hollow, and ſomewhat lower than the Sides of the Banks by eight or ten Inches, that the Rain may deſcend to their Roots, which is of great Advantage to their Growth, and by far better than by the old Ways, where the Banks are too much ſloping, and the Roots of the Set are ſeldom wetted, even in a moiſt Seaſon, the *Summer* following: but if it prove dry, many of the Sets, eſpecially the late planted, will periſh; and even few of thoſe that had been planted in the latter End of *April* (the *Summer* happening to be ſomewhat dry) eſcaped.

The Planting being thus advanced, the next Care is *Fencing*; by ſetting a Hedge of about twenty Inches high upon the Top of the Bank on each Side thereof, leaning a little outwards from the Sets, which will protect them as well (if not better) than a Hedge of three Feet, or four Inches more, ſtanding on the Surface of the Ground, which being raiſed with the Turfs and Sods about twenty Inches, and the Hedge about twenty Inches more, will make three Feet four Inches; ſo as no Cattle can approach the dead Hedge to prejudice it, unleſs they ſet their Feet in the Ditch itſelf, which will be at leaſt a Foot deep; and from the Bottom of the Foſſe to the Top of the Hedge about four Feet and a half, which they can hardly reach over to crop the *Quick*, as they might in the old Way; and beſides, ſuch an Hedge will endure a Year longer.

He ſays, he had an Hedge which had ſtood five Years; and tho' nine or ten Feet were ſufficient for both Ditches and Banks, yet where the Ground is but indifferent, it is better Huſbandry to take twelve Feet, which will allow of a Bank at leaſt ſix Feet broad, and gives more Scope to place the dead Hedges farther from the Sets; and the Ditches being ſhallow, will in two Years time graze.

As to the Objection, That taking twelve Feet waſtes too much Ground, he affirms, That if twelve Feet in Breadth be taken for a Ditch and Bank, there will no more Ground be waſted than by the common Way; for in that a *Quick* is rarely ſet but there are nine Feet between the dead Hedges, which is intirely loſt all the time of fencing; whereas with double Ditches there remain at leaſt eighteen Inches on each

Side where the Turfs were ſet on Edge, that bear more Graſs than when it lay on the flat.

But admitting it did totally lay waſte three Feet of Ground, the Damage were very inconſiderable, ſince forty Perch in Length, two hundred and twenty Yards, which make Perches 7, 25″, 9′, or 7 Pole ½, which at 13*s.* and 4*d.* the Acre, amounts not to 7*d.* ½ *per Annum.*

Now that this is not only the beſt but cheapeſt Way of *Quick-ſetting*, will appear by comparing the Charge of both.

In the uſual Way, the Charge of a three Foot Ditch is four Pence *per* Pole, the Owner providing Sets: If the Workman finds them, he will have for making the ſaid Ditch, and ſetting them, eight Pence *per* Pole, and for hedging, two Pence; that is, for both Sides, four Pence the Pole: Which renders the Charge of Hedging, Ditching, and Sets, twelve Pence the Pole; that is, for forty Rods in Length, forty Shillings.

Then one Load of Wood out of the Copſe coſts (with the Carriage, tho' but two or three Miles Diſtance) ten Shillings, which will ſeldom hedge above eight Poles (ſingle Hedge); but allowing to do ten, to fence forty Poles, there muſt be at leaſt eight Loads of Wood, which coſts four Pounds; making the whole Expence for Ditching, Fencing and Setting forty Poles, to be ſix Pounds, reckoning with the leaſt; for ſcarce any will undertake to do it for leſs than three Shillings and ſix Pence *per* Pole, and then the forty Poles coſt ſeven Pounds.

Whereas with double Ditches, both of them *Settings* and *Sets*, will be done for eight Pence the Pole, and the Huſbandman get as good Wages as with the ſingle Ditch; (for tho' the Labour about them is more, yet the making the Table is ſav'd) which coſts one Pound ſix Shillings and eight Pence; and the Hedges being low, they will make better Wages at Hedging for a Penny a Pole, than at two Pence for common Hedges, which comes to ſix Shillings and eight Pence, for hedging forty Poles on both Sides: Thus, one Load of Wood will fence thirty Poles at leaſt, and forty hedged with two-thirds of Wood leſs than in the other Way, and coſt but one Pound ſix Shillings and eight Pence; which makes the other whole Charge of Sets, Ditching, Fencing, and Wood, but three Pounds.

QUICK BEAM; *vide* Sorbus Sylveſtris.

QUINCE TREE; *vide* Cydonia.

QUINCUNX ORDER, is a Plantation of Trees, diſpoſed originally in a Square conſiſting of five Trees, one at each Corner, and a fifth in the Middle; which Diſpoſition, repeated again and again, forms a regular Grove, Wood, or Wilderneſs; and when view'd by an Angle of the Square or Parallelogram, preſents equal or parallel Alleys.

Or, the *Quincunx* is the Figure of a Plantation of Trees, diſpoſed in ſeveral Rows, both length and breadthwiſe, in ſuch manner, that the firſt Tree of the ſecond Row commences in the Centre of the Square form'd by the two firſt Trees of the firſt Row, and the two firſt of the third, reſembling the Figure of the *Five at Cards*; the fineſt manner of planting Trees to form a Grove.

Trees planted in *Quincunx*, are ſuch as are planted in the following Form.

* * * * *

 * * * *

* * * * *

QUINQUEFOLIUM, [is ſo called of *quinque*, *five*, and *folium*, Lat. *a Leaf*, becauſe this Plant bears five Leaves upon one Stalk: It is call'd *Pentaphyllum*, of πέντε, *five*, and φύλλον, *a Leaf*, i. e. a Plant having *five Leaves*] Cinquefoil.

There are many *Species* of this Plant, which are preſerved in Botanick Gardens for Variety (ſome of which grow wild in divers Parts of *England)*; but as they are never propagated either for Uſe or Beauty, ſo I ſhall not trouble the Reader with an Enumeration of their ſeveral Names.

R A

RACEMIFEROUS, ſignifies *bearing in Cluſters.*

RACEMUS, *a Cluſter*, is a Stalk divided or branched into ſeveral Footſtalks, ſuſtaining the Flowers or Fruits thick ſet together; as are the Bunches of *Grapes*, *Currants*, &c. The firſt of theſe Conditions diſtinguiſhes it from a Spike, the laſt from a Panicle.

RADIATED FLOWERS, are ſuch as have ſeveral Semi-florets ſet round a Diſk, in form of a radiant Star; as are the Flowers of *Daizy*, *Camomil*, &c. Theſe are called *Radiated diſcous Flowers.* Thoſe which have no ſuch Ray, are called *Naked diſcous Flowers*, as the *Wormwood*, *Mugwort*, *Tanſey*, &c.

RADICLE, denotes that Part of the Seed of a Plant, which, upon its Vegetation, becomes a little Root, by which the tender Plant at firſt receives its Nouriſhment before the After-root is formed. This is that Part of the Seed which, in making *Malt*, ſhoots forth, and is called the *Come* or *Comb.*

RADISH; *vide* Raphanus.

RADISH (HORSE); *vide* Cochlearia.

RAIN, is generally accounted to be a crude Vapour of the Earth, but more eſpecially of the Sea, drawn up from thence by the attractive Power of the Sun, or carry'd thitherward by Pulſion, and wafted by the Winds into the Aerial Region; by which Sublimation and Rarefaction, and the virtual Qualities of the Sun and Air, it is formed into Clouds.

The Crudities are diſpelled, and theſe Clouds ſuſpend and hang in the Air: And tho' it may be thought impoſſible that they ſhould be ſo ſuſpended in the Air, by reaſon of their great Weight and Preſſure, yet it will not appear ſo on Conſideration.

When theſe Vapours are thus drawn up to any conſiderable Height, by the Strength of the Air which is underneath them, and which ſtill grows greater and greater, and, by its Motion, undulating this Way and that Way, they riſe gradually through the Air.

This is demonſtrable by Paper Kites, which, after they are raiſed to about ſixty Feet high, do riſe eaſier, and with greater Swiftneſs; and the higher, ſtill the better and ſtronger they fly.

Theſe Clouds being thus arrived into the upper Region of the Air, they are ſoon aggregated and condenſed into Bodies and Clouds.

And tho' they are blown here and there, they are ſtill ſuſpended, 'till they are releaſed from their Impriſonment by the genial Diſpoſition of the Sun, or by the natural Warmth, Humidity, and Rarefaction of the Air.

It is not to be doubted, but that *Rain* drops out of the Clouds, becauſe we don't find it rain but where Clouds are to be ſeen; and by how much the fairer the Weather is, the ſeldomer it rains.

Rain is a very frequent and uſeful Meteor, deſcending from above in form of Drops of Water.

Rain ſeems to differ from Dew, only in this, that Dew falls at ſome particular Times, and in very ſmall Drops, ſo as to be ſeen when it is down, but is ſcarce perceivable while it is falling; whereas *Rain* is groſſer, and falls at any Time.

Rain is apparently a precipitated *Cloud*, as *Clouds* are nothing but Vapours raiſed from Moiſture, Waters, *&c.* and Vapours are demonſtratively nothing elſe but little Bubbles, or *Veſiculæ*, detached from the Waters by the Power of the ſolar or ſubterraneous Heat, or both.

Theſe *Veſiculæ* being ſpecifically lighter than the Atmoſphere, are buoy'd up thereby till they arrive at a Region where the Air is a juſt Balance with them; and here they float, 'till by ſome new Agent they are converted into Clouds, and thence into either *Rain*, *Snow*, *Hail*, *Miſt*, or the like.

But the Agent in this Formation of *Clouds*, *&c.* is a little controverted: The Generality will have it the *Cold*, which conſtantly occupying the ſuperior Regions of the Air, chills and condenſes the *Veſiculæ*, at their Arrival from a warmer Quarter, congregates them together, and occaſions ſeveral of them to coaleſce into little Maſſes; by this Means their Quantity of Matter increaſing in a greater Proportion than their Surface, they become an Over-load to the lighter Air, and deſcend in *Rain.*

The Coldneſs of the *Air* may cauſe the Particles of the Clouds to loſe their Motion, and become leſs able to reſiſt the Gravity of the incumbent Air, and conſequently to yield to its Preſſure, and fall to the Ground.

Dr. *Derham* accounts for the Precipitation hence, That the *Veſiculæ* being full of Air, when they meet with a colder Air than that they contain, their Air is contracted into a leſs Space, and conſequently their watery Shell or Caſe rendered thicker, ſo as to become heavier than the Air, *&c.*

Others only allow the Cold a Part in the Action, and bring in the Winds as Sharers with it: Indeed it is clear, that a Wind blowing againſt a Cloud will drive its *Veſiculæ* upon one another; by which Means ſeveral of them coaleſcing, as before, will be enabled to deſcend; and the Effect will ſtill be more conſiderable, if two oppoſite Winds blow towards the ſame Place. Add to this, that Clouds already formed, happening to be aggregated by freſh Acceſſions of Vapour continually aſcending, may thence be enabled to deſcend.

The Wind may collect the Vapours in ſuch Abundance, as firſt to form very thick Clouds, and then to ſqueeze thoſe Clouds together, till the watery Particles make Drops too big to hang in the Air.

But the grand Cauſe, according to Monſ. *Rohault*, is ſtill behind; he conceives it to be the Heat of the Air, which, after continuing for ſome Time near the Earth, is at length carried up on high by a Wind, and there thawing the frozen *Villi*, or Flocks of the half-frozen *Veſiculæ*, reduces them into Drops, which coaleſcing, deſcend, and have their Diſſolution perfected in their Progreſs thro' the lower and warmer Stages of the Atmoſphere.

M. *Le Clerc*, and others, aſcribe this Deſcent of the Clouds rather to an Alteration of the Atmoſphere, than of the *Veſiculæ*, and ſuppoſe it to proceed from a Diminution of the Spring or elaſtick Force of the Air.

This Elaſticity, which depends chiefly, or wholly, upon the dry terrene Exhalations being weaken'd, the Atmoſphere ſinks under its Burthen, and the Clouds fall upon the common Principle of Precipitation.

Now the little *Veſiculæ*, by any or all of theſe Means, being once upon the Deſcent, will perſiſt therein, notwithſtanding the Increaſe of Reſiſtance they every Moment meet withal, in their Progreſs thro' ſtill denſer and denſer Parts of the Atmoſphere.

For as they all tend towards the ſame Point, *viz.* the Centre of the Earth, the farther they fall the more Coalitions will they make; and the more Coalitions, the more Matter there will be under the ſame Surface: the Surface only increaſing as the Squares, but the Solidity as the Cubes; and the more Matter under the ſame Surface, the leſs Friction or Reſiſtance there will be to the ſame Matter.

Thus, if the Cold, the Wind, *&c.* happen to act early enough to precipitate the *Veſiculæ*, ere they are arrived at any conſiderable Height, the Coalitions being few in ſo ſhort a Deſcent, the Drops will be proportionably ſmall; and thus is form'd what we call *Dew*.

If the Vapours prove more copious, and riſe a little higher, we have a *Miſt* or *Fog*.

A little higher ſtill, and they produce a ſmall *Rain*.

If they neither meet with Cold or Wind enough to condenſe or diſſipate them, they form a heavy, thick, *dark Sky*, which laſts ſometimes ſeveral Weeks.

Hence we may account for many of the Phænomena of the Weather; e. g. Why a cold, is always a wet *Summer*, and a warm, a dry one; becauſe the Principle of Precipitation is had in the one Caſe, and wanting in the other.

Why we have ordinarily moſt *Rain* about the Equinoxes; becauſe the Vapours ariſe more plentifully than ordinary in the *Spring*, as the Earth becomes looſened from the brumal Conſtipations; and becauſe as the Sun recedes from us in *Autumn* the Cold increaſing, the Vapours that had lingred above, during the *Summer* Heats, are now diſpatched down.

Why a ſettled, thick, cloſe Sky ſeldom ever *rains*, 'till it has been firſt clear'd; becauſe the equally confuſed Vapours muſt firſt be condenſed and congregated into ſeparate Clouds, to lay the Foundation of *Rain*: by which Means the reſt of the Face of the Heaven is left open, and pervious to the Rays of the Sun, *&c.*

Monſ. *Le Clerc* obſerves, That all Winds do not produce *Rains*; but only ſuch as collect a great Quantity of Vapours. Thus in *Holland*, *Weſt* Winds are *rainy*, becauſe they come from the Ocean, and blow up the Vapours; *Eaſt* Winds blow clear, becauſe they come over vaſt Tracts of Land; *North* Winds are *rainy*, becauſe they come from the *North* Sea; but not ſo *rainy* as the *Weſt*, becauſe the cold *North* does not yield ſuch a Quantity of Vapours, as the kinder Climate of the *Brittanick* Ocean: *South* Winds bring *Rain* too; for that they conſiſting of Vapours raiſed by the Heat of the Sun, in a hot Quarter, and ſo being elevated above others in the Air, ſeem to lie upon our Clouds, and preſs them down towards the Earth.

But, notwithſtanding, there are many Exceptions in thoſe Caſes, according to the Variety of Cauſes conſpiring to the ſame Effect, many of which we know nothing of.

Again: *Rain* may be produced after this Manner; If the Vapours riſe in ſo great Abundance, as to reach and mingle with the Clouds above them, then they cauſe *Rain* in very large Drops: And this may happen in ſtill, ſultry Weather; for then the Clouds which are over our Heads have no ſenſible Motion, and in the mean time the Heat fills the Air with Vapours; which joining with the Clouds, and ſo being ſtopp'd in their Progreſs, open a Paſſage for the Stores in the Clouds to deſcend upon the Earth.

Sometimes alſo, the warm Wind thaws the Clouds into Drops, as we ſee Snow diſſolved by Heat: Now by how much the thicker and ſooner any ſuch Cloud was gathered, the larger are the Drops that come from it, becauſe a greater Store of Vapours was condenſed there. From thence it is, that in *Summer* time we have ſudden Showers of *Rain* in very large Drops.

It ought alſo to be remember'd, that in thoſe Countries which lie between the Tropicks, where they have the Sun vertical, the *Rain* pours down, for ſeveral Weeks together, more like Pails-full than Drops. And it is very probable that this is the Cauſe; *viz.* Becauſe at that time the Sun draws up abundance of Vapours, and rarefies them extremely, ſo that they are elevated as high as poſſible, and then are precipitated at once, being too copious and heavy to hang any longer in the Air: And beſides, there may ſometimes be a Concurrence of neighbouring Vapours, which will be ready to croud into that Part in the Air, which is moſt rarefied by the Heat of the Sun meeting with the Vapours, which are raiſed in that Place, and produce very great Clouds and *Rain*.

If any aſk how the Drops of falling Water come to be round, as in *Rain*? It is anſwered, That this does not happen by any Diſpoſition peculiar to the Water; but becauſe the Drops are equally preſſed by the Air on every Side, and thereby forced into a round Figure: the Reſiſtance of the Particles, as well as the Preſſure of the Air, being equal every way. But others give other Reaſons for it.

In *Rain* there are two diſtinct *Properties* or *Species*; the one which ſerves for the Diſſolution of the Salts of the Earth, and the other is a *Terreſtrial Matter*, which it meets with in its *Sublimation*, which may, with ſome Propriety, be call'd either *Salt* or *Nitre*: and both theſe are uſeful in the Buſineſs of *Vegetation*.

Rain is operative in diſſolving the *Salts* that are in the Earth, and alſo cools and bathes the Cortex or Skin of all Vegetables, and, by a ſort of Relaxation, cauſes the Sap to paſs up more freely, and by that Means the Tree to grow and ſhoot the better.

Theſe foggy, humid Vapours ariſing out of the Ground, *&c.* of which *Rain* is formed, would inevitably ſtagnate and poiſon the whole Face of the Earth, were they not ſublimated by the Air, and drawn up by the Aſſiſtance of the Sun into the upper Regions; but being there rarefied, they are made of ſecond Uſe in Vegetation.

As to the Quantity of *Rain* that falls, its Proportion in ſeveral Places at the ſame Time, and in the ſame Place at ſeveral Times, we have Store of Obſervations, Journals, *&c.* in the Memoirs of the *French* Academy, the *Philoſophical Tranſactions*, &c. an Idea of which take as follows.

Upon meaſuring, then, the *Rain* falling yearly, its Depth, at a Medium, is found as in the following Table:

Depth of RAIN *falling Yearly, and its Proportion in ſeveral Places.*

At *Townley* in *Lancaſhire*, obſerved by Mr. *Townley* - - - - -	42 ½ Inches
Upminſter in *Eſſex*, by Dr. *Derham* - - - - - - - - - - -	19 ¼
Zurich in *Switzerland*, by Dr. *Sceutcher* - - - - - - - - - -	32 ¼
Piſa in *Italy*, by Dr. *Mich. Ang. Tilli* - - - - - - - - - -	43 ¼
Paris in *France*, by M. *de la Hire* - - - - - - - - - -	19
Liſle in *Flanders*, by M. *de Vauban* - - - - - - - - - -	24

The Reverend Dr. *Hales*, in his excellent Treatiſe of *Vegetable Staticks*, tells us, That the Quantity of *Rain* and *Dew* that falls in a Year, is, at a Medium, 22 Inches; and that the Quantity of the Earth's Evaporation in a Year, is at leaſt $9+\frac{1}{2}$ Inches, ſince that is the Rate at which it evaporates in a *Summer*'s Day; from which $9+\frac{1}{2}$ Inches is to be deducted 3. 39 Inches, for circulating daily Dew, there remains 6. 2 Inches; which 6. 2 Inches deducted from the Quantity of *Rain* which falls in a Year, there remains at leaſt 16 Inches Depth to repleniſh the Earth with Moiſture for Vegetation, and to ſupply Springs and Rivers.

Hence we find, that 22 Inches Depth of *Rain* in a Year, is ſufficient for all the Purpoſes of Nature, in ſuch flat Countries as is that about *Teddington* near *Hampton-Court*: But in the Hill Countries, as in *Lancaſhire*, there falls 42 Inches Depth of *Rain-water*; from which deducting 7 Inches for Evaporation, there remains 35 Inches Depth of Water, beſides great Supplies from much more plentiful Dews than fall in plain Countries.

Which vaſt Stores ſeem ſo abundantly ſufficient to anſwer the great Quantity of Water, which is convey'd away by Springs and Rivers from thoſe Hills, that we need not have recourſe for Supplies to the great Abyſs, whoſe Surface at High-Water, is ſurmounted ſome hundreds of Feet by ordinary Hills, and ſome thouſands of Feet by thoſe vaſt Hills, from whence the longeſt and greateſt Rivers take their Riſe.

RAINBOW, a Meteor in Form of a Party-colour'd Arch or Semi-circle, exhibited in a rainy Sky oppoſite to the Sun, by the Refraction of his Rays in the Drops of falling *Rain*.

The *Rainbow*, Sir *Iſaac Newton* obſerves, never appears but where it rains in the Sun-ſhine, and may be repreſented artificially, by contriving Water to fall in little Drops like *Rain*, through which the Sun ſhining, exhibits a Bow to the Spectator's Eye, placed between the Sun and the Drops; eſpecially if a dark Body, *e. g.* a Black Cloth to be diſpoſed beyond the Drops.

Auton de Denicinis firſt accounted for the *Rainbow* in 1611: He explain'd at large how it was form'd by Refraction and Reflexion of the Sun-beams in ſpherical Drops of Water, and confirm'd his Explication by Experiments made with Glaſs Globes, *&c.* full of Water; wherein he was follow'd by *Des Cartes*, who mended and improv'd upon his Account.

But as they were both in the Dark, as to the true Origin of Colours, their Explications are defective, and in ſome Things erroneous; which it is one of the Glories of the *Newtonian* Doctrine of Colours, to ſupply and correct.

The following Properties are aſcribed to the *Rainbow*:

1. That it never appears but in a Place oppoſite to the Sun, ſo that when we look directly at it, the Sun is always behind us.

2. That when the *Rainbow* appears, it always rains ſomewhere.

3. That the conſtant Order of the Colours is, that the outmoſt is *Red* or Saffron-colour, the next is *Yellow*, the third is *Green*, the fourth and inmoſt is *Violet* or *Blue*; but theſe Colours are not always equally bright.

4. Two *Rainbows* appear together, one of which is higher and larger than the other, and ſhews the aforeſaid Colours, but in an inverted Order.

5. The *Rainbow* is always exactly round, but does not always appear equally intire, the upper or lower Parts being very often wanting.

6. Its apparent Breadth is always the ſame.

7. That thoſe who ſtand upon plain low Ground, never ſee above half its Circle, and often times not ſo much.

8. The higher the Sun is above the Horizon, the leſs of the Circle is ſeen; and, if there be no Cloud to hinder, the lower, the more of it.

9. That never any *Rainbow* appears, when the Sun is above 41 Degrees 46 Minutes high.

Lunar (Rainbow): The Moon alſo ſometimes exhibits the Phænomena of an *Iris* or *Bow*, by the Refraction of her Rays in the Drops of *Ruin* in the Night-time.

Ariſtotle ſays, he was the firſt that ever obſerv'd it; and adds, that it never happens, *i. e.* is viſible, but at the time of the Full Moon, her Light at other times being too faint to affect the Sight. After two Refractions and one Reflection, the *Lunar Iris* has all the Colours of the *Solar* very diſtinct and pleaſant, only faint, in Compariſon of the other, both from the different Intenſity of the Rays, and the different Diſpoſition of the Medium.

Marine (Rainbow) is a Phænomenon ſometimes obſerved in a much agitated Sea, when the Wind ſweeping Part of the

Tops of the Waves, carries them aloft ; ſo that the Sun's Rays falling upon them, are refracted, &c. as in a common Shower, and paint the Colours of the Bow.

F. *Bourzes*, in the *Philoſophical Tranſactions*, obſerves, that the Colours of the *Marine Rainbow* are leſs lively, diſtinct, and of leſs Duration, than thoſe of the common *Bow*; that there are ſcarce above two Colours diſtinguiſhable, a dark Yellow on the Side next the Sun, and a pale Green on the oppoſite Side.

But theſe Bows exceed as to Number, there being ſometimes twenty or thirty ſeen together ; they appear at Noonday, and in a Poſition oppoſite to that of the common *Bow*, *i. e.* the Concave Side is turned upwards ; as indeed it is neceſſary it ſhould be, from what may be ſaid in accounting for the Appearance of the *Solar Bow*.

RAMPIONS ; *vide* Campanula raide eſculenta.

RAMUS, *a Branch*, is the Diviſion of a Stalk : In Trees, it is often call'd *a Bough*.

RANDIA.

The *Characters* are ;

It hath a Flower conſiſting of one Leaf, whoſe lower Part is tubulous, but the upper Part is expanded, and for the moſt part divided into five Segments ; the Flower is ſucceeded by an oval Fruit, having but one Cell, which is filled with flat cartilaginous Seeds ſurrounded by a Pulp.

There is but one *Species* of this Plant at preſent known ; *viz.*

RANDIA *fruteſcens, ſpinis bijugis, foliis ſubrotundis, floribus albis. Houſt.* Shrubby Randia, with Spines growing two at a Joint, roundiſh Leaves, and white Flowers. This Plant is figured and deſcribed by Sir *Hans Sloane* in his Hiſtory of *Jamaica*, under the Title of *Lycium forte, foliis ſubrotundis integris, ſpinis & foliis ex adverſo ſitis.* Vol. 1. p. 40.

This Shrub grows plentifully about *La Vera Cruz*, from whence the Seeds were ſent by the late Dr. *William Houſtoun*, who gave this Name to it, in Honour to Mr. *Iſaac Rand*, a curious Botaniſt.

This Shrub riſes to the Height of ten or twelve Feet in the Country of its Growth, and divides into a great Number of Branches, which are always produced by Pairs oppoſite, as are alſo the Leaves and Spines. The Flowers are ſmall, and of a white Colour, which are ſucceeded by hard oval-ſhaped Fruit, about the Size of a large *Spaniſh* Nut, which is full of flat Seeds incloſed in a ſoft blackiſh Pulp.

It is propagated by Seeds, which ſhould be ſown early in the *Spring*, in Pots filled with light freſh Earth, and plunged into a Hot-bed of Tanners-bark, obſerving to water the Earth frequently to promote the Vegetation of the Seeds. When the Plants come up, they muſt have freſh Air admitted to them every Day, when the Weather is warm, and they muſt be often refreſhed with Water. In about a Month's time after the Plants come up, they will be fit to tranſplant ; when they ſhould be carefully taken out of the Pots, and each planted into a ſeparate ſmall Pot filled with light freſh Earth, and then plunged into the Hot-bed again ; where they muſt be ſcreened from the Sun until they have taken new Root, after which Time they muſt have Air and Moiſture in proportion to the Warmth of the Seaſon. The Plants may remain in the Hot-bed till toward *Michaelmas*, when the Nights begin to be cold ; at which time they ſhould be removed into the Stove ; and if they are plunged in the Bark-bed, it will greatly forward their Growth, tho' they will live in the dry Stove, if they are kept in a moderate Temperature of Heat, and are frequently watered. During the two firſt Seaſons, while the Plants are young, it will be proper to keep them conſtantly in the Stove (but then their Leaves muſt be waſhed, whenever they contract Filth) ; which will bring them forward : but after the Plants have obtained Strength, they may be expoſed every *Summer* to the open Air, provided they are placed in a warm Situation : but in *Winter* they muſt be conſtantly placed in a Stove, and kept in a moderate Warmth ; otherwiſe they will not live in this Country.

The Leaves of this Plant continue green throughout the Year, which renders the Plant valuable, becauſe it makes an agreeable Variety in the *Winter* Seaſon, when mixed with other tender Plants. Sir *Hans Sloane* found this Plant in the Iſland of *Barbadoes*.

RANUNCULUS, [ſo call'd, as ſome ſay, from *Rana*, Lat. *a Frog*, on account of its delighting to grow in moiſt Places, which Frogs frequent] Crowfoot.

The *Characters* are ;

The Flower conſiſts of ſeveral Leaves, which are placed in a circular Order, and expand in form of a Roſe ; having, for the moſt part, a many-leafed Empalement or Flower-cup ; out of the Middle of the Flower riſes the Pointal, which afterwards becomes a Fruit, either round, cylindrical, or ſpiked ; to the Axis of which, as a Placenta, adhere many Seeds, for the moſt part naked.

The *Species* are ;

1. RANUNCULUS *hortenſis erectus, flore pleno. C. B. P.* Common Yellow Crowfoot, with a double Flower.
2. RANUNCULUS *repens, flore pleno. J. B.* Common Creeping Crowfoot, with a double Flower.
3. RANUNCULUS *montanus, aconiti folio, albus, flore minore. C. B. P.* Mountain Crowfoot, with a white Flower.
4. RANUNCULUS *folio aconiti, flore albo multiplici. C. B. P.* Crowfoot, with a Monk's-hood Leaf, and a double white Flower, *commonly call'd* The Fair Maid of *France*.
5. RANUNCULUS *bulboſus, flore pleno. C. B. P.* Common Bulbous-rooted Crowfoot, with a double Flower.
6. RANUNCULUS *Conſtantinopolitanus, flore ſanguineo pleno. J. B.* Common *Ranunculus*, with a double bloody Flower.
7. RANUNCULUS *aſphodeli radice, prolifer miniatus. C. B. P. Ranunculus* with an Aſphodel Root, and Childing Carmine Flowers, *commonly call'd* Turks Turban.
8. RANUNCULUS *aſiaticus polyclonos, ſive grumoſa radice, ſecundus. J. B.* Aſiatick *Ranunculus* with many Heads, and a grumoſe Root, *commonly call'd* Sphericus.
9. RANUNCULUS *aſphodeli radice, flore ſanguineo maximo. H. R. Par.* Aſphodel-rooted *Ranunculus*, with a very large Flower, *commonly call'd* The Monſter.
10. RANUNCULUS *aſphodeli radice, flore ſubphœnicio rubente. C. B. P.* Aſphodel-rooted *Ranunculus*, with purpliſh-red Flowers, *commonly call'd* Marvelia.
11. RANUNCULUS *aſphodeli radice, flore luteo variegato. H. R. Par.* Aſphodel-rooted *Ranunculus*, with a yellow variegated Flower.
12. RANUNCULUS *Alepus, grumoſa radice, flore lineis rubris & luteis ſtriato. H. R. Par.* Grumoſe-rooted Crowfoot with a Flower-ſtrip'd with red and yellow Lines, *commonly call'd* Ranunculus of *Aleppo*.
13. RANUNCULUS *aſphodeli radice, flore flavo, venis rubris diſtincto ; Boſvel dictus. H. R. Par.* Crowfoot with an Aſphodel Root and yellow Flower with red Veins, *commonly call'd* Boſvel.
14. RANUNCULUS *Alepus, grumoſa radice, flore miniato, per oras luteo. H. R. Par.* Aleppo Crowfoot with a grumoſe Root, and a carmine Flower, bordered with yellow.
15. RANUNCULUS *flore pleno flaveſcente, & rubris lineis elegantiſſime variegato. H. R. Par.* Crowfoot with a double yellow Flower curiouſly ſtrip'd with red Lines, *commonly called* Aurora.
16. RANUNCULUS *aſphodeli radice, flore pleno albo parvo, rubris ſtriis diſtincto. H. R. Monſp.* Crowfoot with an Aſphodel Root, and a ſmall double white Flower ſtrip'd with red.
17. RANUNCULUS *aſphodeli radice, flore pleno magno lacteo, ſuperius lituris rubris eleganter picto. Boerh. Ind.* Crowfoot with an Aſphodel Root, and a large double white Flower, mark'd above with red Spots, *commonly called* the Seraphick.

Theſe are moſt of them old Flowers, which have been long cultivated in the *Engliſh* Gardens: The five firſt-mentioned Sorts are very hardy Plants, and will thrive extremely well in ſhady Borders ; theſe require no other Culture, but to take up their Roots every other Year, when their Leaves decay, and part them, planting out the Off-ſets in other Borders, leſt by permitting them to grow too large, they rot each other. The creeping Sort will require to be oftner tranſplanted, otherwiſe it will ſpread over every thing that grows near it. Theſe do all produce handſome double Flowers, which continue long in Beauty, and afford an agreeable Variety, and being hardy, are worthy of a Place in every good Garden.

The other Sorts were originally brought from *Turkey*, and were formerly in great Eſteem in *England*, but of late Years there have been introduced many other Sorts of a differing Kind, from *Perſia*, amongſt which are many with ſemi-double Flowers, which produce Seeds, from which there are ſuch prodigious Varieties of new Flowers annually obtained, which are ſo large, and of ſuch Variety of beautiful Colours, as to exceed all other Flowers of that Seaſon, and even vie with the moſt beautiful Carnations: Theſe are, many of them, finely ſcented, and the Roots, when ſtrong, do generally produce eight, ten, or twelve Flowers upon each, which ſucceeding each other, do continue in Beauty a full Month or longer, according to the Heat of the Seaſon, or the Care taken to defend them from the Injuries of the Weather; all which excellent Qualities have rendered them ſo valuable, that the old Sorts here-named are almoſt diſregarded, except in ſome old Gardens; but however, as they are ſtill preſerved by ſome Perſons, ſo I ſhall briefly ſet down their Management, before I proceed to that of the new Kinds, which muſt be treated in a different manner from theſe.

All theſe very double Flowers do never produce Seeds, ſo that they are only multiplied by Off-ſets from their Roots, which they generally produce in good Plenty, if planted in a good Soil, and duly attended in *Winter*. The Seaſon for planting their Roots is any Time in *October*; for if they are planted ſooner, they are apt to come up in a ſhort Time, and grow pretty rank before Winter, whereby they will be in greater Danger of ſuffering by Froſt; and if they are planted much later, they will be in Danger of periſhing underground; ſo that if you keep them out of the Ground any longer than the Beginning of November, it will be the better way to defer the planting of them till the latter End of *January*, or the Beginning of *February*, after the great Froſts are paſt.

The Beds in which theſe Roots are planted, ſhould be made with freſh, light, ſandy Earth, at leaſt a Foot deep: The beſt Soil for theſe Roots may be compoſed in the following Manner, *viz.* Take a Quantity of freſh Earth from a rich up-land Paſture, about ſix Inches deep, together with the Green-ſward; this ſhould be laid in a Heap to rot for twelve Months before it is uſed, obſerving to turn it over very often, to ſweeten it, and break the Clods; to this you ſhould add a proportionable Quantity of Sea or Drift Sand, according as the Earth is lighter or ſtiffer; if it be light and inclining to a Sand, there ſhould be no Sand added; but if it be a hazel Loam, one Load of Sand will be ſufficient for four Loads of Earth: but if the Earth is ſtrong and heavy, the Sand ſhould be added in a greater Proportion; but you ſhould often turn it over, in order to unite their Parts well together, before it is put into the Beds.

The Depth which this ſhould be laid in the Beds, muſt be about a Foot; this ſhould be below the Surface, in Proportion to the Drineſs or Moiſture of the Place where they are ſituated; which in dry Ground ſhould be eight Inches below the Surface, and the Beds rais'd four Inches above; but in a moiſt Place they ſhould be ſix Inches below, and ſix above the Ground; and in this Caſe it will be very proper to lay ſome Rubbiſh and Stones in the Bottom of each Bed, to drain off the Moiſture. This Earth I would by no means have ſcreen'd very fine, but only in turning it over each Time, you ſhould be careful to break the Clods, and throw out all large Stones, which will be ſufficient; for if it is made very fine, when the great Rains in *Winter* come on, it will cauſe the Earth to bind into one ſolid Lump, whereby the Moiſture will be detained, and the Roots not being able to extend their tender Fibres, will rot: Of this I have ſeen many Examples, but one particularly to my Coſt; when I had procured a fine Parcel of theſe Roots from abroad, and being deſirous of having them thrive very well, I took great Pains to ſcreen the Earth of my Beds very fine, which I laid near two Feet deep, and planted a good Part of my Roots therein; but the Seaſon advancing, and having a great deal of other Buſineſs upon my Hands, I did not ſcreen the Earth of all my Beds, but planted ſome of them without doing any thing more than raking them; and the Succeſs was, that the Roots in thoſe Beds which were ſcreened, did, great Part of them, intirely rot, and the remaining Part were ſo weak, as not to produce any good Flowers; whereas thoſe which were planted in the Beds which were not ſcreened, did thrive and flower very well, and ſcarce any of the Roots failed, tho' the Earth of all the Beds was the ſame, and were in the ſame Situation, both with regard to Wind and Sun, ſo that the Damage which thoſe Roots ſuſtained, was owing intirely to the Fineneſs of the Earth; and this I have ſeveral Times ſince obſerved in other Gardens.

The beds being thus prepared, ſhould lie a Fortnight to ſettle, before the Roots are planted, that there may be no Danger of the Earth ſettling unequally after they are planted, which would prejudice the Roots, by having hollow Places in ſome Parts of the Bed, to which the Water would run and lodge, and ſo rot the Roots in ſuch Places. Then having levelled the Earth, laying the Surface a little rounding, you ſhould mark out the Rows by a Line, at about four Inches Diſtance each way, ſo that the Roots may be planted every way in ſtrait Lines; then you ſhould open the Earth with your Fingers, at each Croſs where the Roots are to be planted, about two Inches deep, placing the Roots exactly in the Middle, with their Crowns upright, then with the Head of a Rake you ſhould draw the Earth upon the Surface of the Bed level, whereby the Top of the Roots will be about an Inch covered with Earth, which will be ſufficient at firſt: This Work ſhould be done in dry Weather, becauſe the Earth will then work better than if it were wet; but the ſooner after Planting there happens to be Rain, the better it will be for the Roots; for if it ſhould prove dry Weather long after, and the Earth of the Beds be very dry, the Roots will be ſubject to mould and decay; therefore in ſuch a Caſe it will be proper to give a little Water to the Beds, if there ſhould no Rain happen in a Fortnight's Time, which is very rare at that Seaſon of the Year, ſo that they will ſeldom be in Danger of ſuffering that way.

When the Roots are thus planted, there will no more be required until toward the Middle of *November*, by which Time they will begin to heave the Ground, and their Buds appear, when you ſhould lay a little of the ſame freſh Earth of which the Beds were compoſed, about an Inch thick all over the Beds, which will greatly defend the Crown of the Root from Froſt: And when you perceive the Buds to break through this ſecond Covering, if it ſhould prove a very hard Froſt, it will be very proper to arch the Beds over with Hoops, and cover them with Mats, eſpecially in the *Spring*, when the Flower-buds will begin to appear; for if they are expoſed to too much Froſt or blighting Winds at that Seaſon, their Flowers do ſeldom open fairly, and many times the Roots are deſtroyed: But this happens more frequently to the *Perſian* Kinds, which are tenderer, than to theſe Sorts, which are pretty hardy; for which Reaſon theſe are often planted in open Borders, intermix'd with other Flowers, though in very hard *Winters* theſe are apt to ſuffer, where there is not Care taken to guard off the Froſt.

In the Beginning of *March* the Flower ſtems will begin to riſe, at which Time you ſhould carefully clear the Beds from Weeds, and ſtir the Earth with your Fingers between the Roots, being very careful not to injure them; this will not only make the Beds appear handſome, but alſo greatly ſtrengthen their Flowers. When the Flowers are paſt, and the Leaves are withered, you ſhould take up the Roots, and carefully clear them from the Earth, then ſpread them upon a Mat to dry, in a ſhady Place, after which they may be put up in Bags or Boxes in a dry Room, until the *October* following, which is the Seaſon for planting them again.

Thus having directed how theſe Sorts are to be cultivated, I ſhall proceed to treat of the *Perſian* Kinds, where I ſhall only mention in what Particulars theſe are to be treated different from thoſe already mentioned.

* Theſe Flowers are not only propagated by Off-ſets from the old Roots, as the former, but are alſo multiplied by Seeds, which the ſemi-double Kinds do produce in Plenty. Therefore whoever is deſirous to have theſe in Perfection, ſhould annually ſow their Seeds, from which new Varieties will be every Year produced; but in order hereto, you ſhould be careful in ſaving the Seed, or in procuring it from ſuch Perſons as underſtand how to ſave it; that is, who will be careful not to leave any Flowers for Seeds, but ſuch as have three or four Rows of Petals at leaſt, and are well coloured; for ſince theſe Flowers do increaſe ſo plentifully, it is not worth the Trouble to ſow any indifferent Seeds, becauſe there can be but little Hopes of obtaining any good Flowers from ſuch Seeds.

Being prepared with Seeds, about the Middle of *Auguſt*, which is the proper Seaſon for ſowing of them, you ſhould get ſome large Pots, flat Seed-pans or Boxes, (of either as many as you have Seeds to ſow) theſe ſhould be filled with light, ſandy, rich Earth, levelling the Surface very even, then ſow the Seeds thereon pretty thick, and cover it about a Quarter of an Inch thick with the ſame light Earth; after which you ſhould remove theſe Pots into a ſhady Situation, where they may have the Morning Sun until ten of the Clock, and if the Seaſon ſhould prove dry, you muſt often refreſh them with Water, being very careful in doing of this, ſo as not to waſh the Seeds out of the Ground. In this Situation the Pots ſhould remain until the Beginning of *October*, by which Time the Plants will begin to come up, (though ſometimes the Seeds will remain in the Earth until *November*, before the Plants appear) when you ſhould remove the Pots into a more open Expoſure, where they may have full Sun, which at that Time is neceſſary to exhale the Moiſture of the Earth; but toward the Middle of *November*, when you are apprehenſive of Froſt, the Pots ſhould be removed under a common Hot-bed Frame, where they may be covered with the Glaſſes in the Night-time, and in bad Weather; but in the Day, when the Weather is mild, they ſhould be entirely opened, otherwiſe the Plants will draw up too weak: The only Danger they are in, is from violent Rains and Froſts, the firſt often rooting the tender Plants, and the Froſt will often turn them out of the Ground, therefore they ſhould be carefully guarded againſt both of theſe.

In the *Spring*, as the Seaſon grows warm, ſo theſe Pots ſhould be expoſed to the open Air, placing them at firſt near the Shelter of a Hedge, to protect them from the cold Winds; but towards the latter End of *March*, or the Beginning of *April*, they ſhould be removed again into a more ſhady Situation, according to the Warmth of the Seaſon; and if it ſhould prove dry, they muſt ſometimes be refreſhed with Water; but you ſhould be careful not to give it to them in great Quantities, which is very apt to rot theſe tender Roots; and in the Middle or latter End of *April*, they ſhould be placed where they may have only the Morning Sun: In which Place they may remain till their Leaves decay, when they may be taken out of the Earth, and the Roots dry'd in a ſhady Place; after which they may be put in Bags, and preſerved in a dry Place until the *October* following, when they muſt be planted in the Manner before directed for the old Roots.

The *Spring* following theſe Roots will flower, at which Time you ſhould carefully mark ſuch of them as are worthy to be preſerved; and the ſingle or bad-coloured Flowers may be pulled up and thrown away, which is the ſureſt Method of removing them from the good Sorts; for if they are permitted to remain together until their Leaves decay, there may be ſome Off-ſets of the bad Sorts mixed with the good Flowers. You ſhould not ſuffer thoſe Flowers, which you intend to blow fine the ſucceeding Year, to bear Seeds, but cut off the Flowers when they begin to decay; for thoſe Roots which have produced Seeds, do ſeldom flower well afterwards, nor will the principal old Root, which has flower'd ſtrong, ever blow ſo fair as will the Off-ſets, which is what ſhould be principally obſerv'd, when a Perſon purchaſes any of theſe Roots; and a great Part of the Complaints made by thoſe who have bought theſe Roots at a dear Rate, is principally owing to this; for the Perſons who ſold them being appriſed of this Matter, have parted with their old Roots to their Purchaſers, and reſerved the Off-ſets for their own Uſe; which old Roots have often ſo much degenerated from what they were the preceding Year, as to cauſe a Suſpicion, whether the Perſons they were purchaſed from had not changed the Roots; and this Degeneracy always attends theſe Flowers, after having flower'd extremely large and fair, or that they have been permitted to ſeed: So that it is abſolutely neceſſary to ſow Seeds every Year, in order to preſerve a Succeſſion of good Flowers.

The Soil which theſe delight moſt in, is a rich, light, ſandy Earth; but whatever Dung is added to the Earth, ſhould be very rotten, and ought to be mixed with the Earth at leaſt ſix Months before it be uſed: During which Time it ſhould be often turned over to mix the Parts well together; and the lighter this Earth is, the better will the Flowers thrive: But, as I before ſaid, it is by no means adviſeable to ſift or ſcreen it too fine, for the Reaſons already given. Some there are who mix rotten Tan, or Saw-duſt, with their Earth, to render it light; but this is alſo bad for theſe Flowers, as I have ſeveral times experienced, eſpecially if either of theſe be not ſo rotten as to have quite loſt its Appearance, and reduced to Earth; for tho' the Roots will often come up very ſtrong, and flouriſh very vigorouſly till the Beginning of *February*, yet at that Seaſon it is very common to have them die off in large Patches: Which when I have obſerv'd, I have ſearch'd to the Bottom of the Roots, and found ſome Part of the Tan or Saw-duſt lying near them, which has detain'd the Moiſture, and thereby rotted the Roots.

The Manner of preparing the Beds, and the Diſtance and Method of planting the Roots, being exactly the ſame as hath been already directed for the old Sorts, I ſhall not repeat it here, but will only obſerve, that theſe Flowers being more tender than the others, muſt be protected from hard Froſts, and cutting ſharp Winds, eſpecially after *Chriſtmas*, when their Flower-buds are forming; for if they are neglected at that Seaſon, their Flowers will rarely prove fair; nor ſhould you ſuffer them to receive too much Wet in *Winter* or *Spring*, which is equally as injurious to them as Froſt. In planting of theſe Roots you ſhould obſerve to place the ſemi-double Kinds, from which you intend to ſave Seeds, in ſeparate Beds by themſelves, and not intermix them with the double Flowers, becauſe they will require to be treated in a different Manner; for when the Flowers of the ſemi-double Kinds begin to fade, you ſhould carefully guard them from Wet; for if they are permitted to receive hard Rains, or are water'd at that Seaſon, the Seeds do rarely come to Maturity, or are ſo weak, that ſcarce one in fifty of them will grow.

When the Seed begins to ripen (which may be eaſily known by ſeparating from the Axis, and falling) you ſhould look it over every Day, gathering it as it ripens; for there will be a conſiderable Diſtance in the Seeds of the ſame Bed coming to Maturity, at leaſt a Fortnight, and ſometimes three Weeks or a Month. When you gather the Seed, it ſhould not be expoſed to the Sun, but ſpread to dry in a ſhady Place; after which, you muſt put it up where the Vermin cannot come to it, until the Time of ſowing it.

By this Method of ſowing Seeds every Year, you will not only increaſe your Stock of Roots, but alſo raiſe new Varieties, which may be greatly mended by changing the Seeds into freſh Ground; for if a Perſon continually ſows his Seed in the ſame Garden many Years, they will not produce near ſo fine Flowers, as if he procured his Seeds at ſome Diſtance; which is alſo the Caſe with moſt other Plants.

It will alſo be neceſſary to take away all the Earth out of the Beds in which the Roots were blown the precedent Year, and put in new, if you intend to plant *Ranunculus*'s there again; otherwiſe they will not thrive near ſo well, notwithſtanding you may add ſome new Compoſt to the Beds: And this is what all the curious Floriſts do continually obſerve.

RAPA; Turnip.

The *Characters* are;

The Flower conſiſts of four Leaves, which are placed in form of a Croſs; out of the Flower-cup riſes the Pointal, which afterwards turns to a Pod, divided into two Cells by an intermediate Partition, into which the Valves adhere on both Sides, and are full of roundiſh Seeds: To theſe Marks muſt be added, a carneous and tuberoſe Root.

The *Species* are;

1. RAPA *ſativa rotunda, radice candida. C. B. P.* Round Garden Turnip, with a white Root.
2. RAPA *ſativa rotunda, radice ſupra terram viridi. Boerh. Ind.* Round Garden Turnip, whoſe Root is green above Ground.
3. RAPA *ſativa rotunda, radice punicea. C. B. P.* Round Garden Turnip, with a purple Root.
4. RAPA *ſativa rotunda, radice obſoleta nigricante. C. B. P.* Round Garden Turnip, with a ruſty black Root.
5. RAPA *ſativa rotunda, radice foris & intus flaveſcente. C. B. P.* Round Garden Turnip, with a yellow Root both within and without.
6. RAPA *radice oblonga, ſeu fœmina. C. B. P.* Oblong or Female Turnip.

There are ſome other Varieties of this Plant, which differ in the Shape or Colour of their Roots; but as they are only ſeminal Variations, ſo it would be needleſs to enumerate them in this Place, ſince it is the firſt and third Sort here mentioned, which are chiefly cultivated for the Table in *England*. The yellow Sort, and that with long Roots, were formerly more cultivated than at preſent; for it is now very rare to ſee either of theſe brought to the Markets, though ſome Years ſince they were ſold in as great Plenty as the common round Sort.

Turnips delight in a light, ſandy Soil, which muſt not be rich, for in a rich Soil they grow rank, and are ſticky; but if it be moiſt, they will thrive the better, eſpecially in a freſh Land, where they are always ſweeter than upon an old worn out Soil.

The common Seaſon for ſowing of *Turnips* is any time from the Beginning of *July* to the Middle of *Auguſt*, or a little later; tho' it is not adviſeable to ſow them much after, becauſe, if the *Autumn* ſhould not prove very mild, they will not have time to apple before *Winter*. But notwithſtanding this is the general Seaſon in which the greateſt Part of *Turnips* are ſown in the Country, yet about *London* they are ſown ſucceſſively from *March* to *Auguſt*, by thoſe who propagate them to ſupply the Markets with their Roots; but there is a great Hazard of loſing thoſe which are ſown early in the Year, if the Seaſon ſhould prove dry, by the Fly, which will devour whole Fields of this Plant while young; ſo that where a ſmall Quantity for the Supply of a Family is wanted, it will be abſolutely neceſſary to water them in very dry Weather: And where a Perſon ſows of thoſe Seeds in *April*, *May* and *June*, it ſhould always be upon a moiſt Soil, otherwiſe they ſeldom come to good, the Heat of the Weather

ther at that Seaſon being too great for them upon a dry Soil: But thoſe which are ſown towards the Middle or latter End of *July*, do commonly receive ſome refreſhing Showers to bring them forward: without which, it is very common to have them all deſtroy'd.

Their Seeds ſhould always be ſown upon an open Spot of Ground; for if they are near Hedges, Walls, Buildings, or Trees, they will draw up, and be very long topp'd, but their Roots will not grow to any Size.

They are ſown in great Plenty in the Fields near *London*, not only for the Uſe of the Kitchen, but for Food for Cattle in *Winter*, when other Food fails; and this Way is become a great Improvement to barren, ſandy Lands, particularly in *Norfolk*, where, by the Culture of *Turnips*, many Perſons have doubled the yearly Value of their Ground.

The Land upon which this Seed is ſown, ſhould be plough'd in *May*, and twy-fallow'd in *June*, and made very fine; then the Seed ſhould be ſown pretty thin, (for it being ſmall, a little will ſow a large Piece of Ground, two Pounds of this Seed is ſufficient for an Acre of Land): The Seed muſt be harrowed in, and the Ground rolled with a Wooden Roll, to break the Clods, and make the Surface even: In ten Days or a Fortnight after ſowing, the Plants will come up; at which Time, if the Seaſon ſhould prove dry, they will be in great Danger of being deſtroyed by the Fly: But if it ſo happen, the Ground muſt be ſow'd again, for the Seed being cheap, the chief Expence is the Labour.

When the Plants have got four or five Leaves, they ſhould be houghed to deſtroy the Weeds, and to cut up the Plants where they are too thick, leaving the remaining ones about ſix or eight Inches aſunder each Way, which will be Room enough for the Plants to ſtand for the firſt Houghing: But in the ſecond Houghing, which muſt be performed about three Weeks or a Month after the firſt, they ſhould be cut up, ſo as that the remaining Plants may ſtand fourteen or ſixteen Inches Diſtance, or more, eſpecially if they are deſign'd for feeding of Cattle; for where the Plants are allowed a good Diſtance, the Roots will be proportionably large, ſo that what is loſt in the Number will be over-gained by their Bulk: which is what I have often obſerv'd: But in ſuch Places where they are ſown for the Uſe of the Kitchen, they need not be left at a greater Diſtance than ten Inches or a Foot, becauſe large Roots are not ſo generally eſteem'd for the Table.

In order to ſave good *Turnip* Seeds, you ſhould tranſplant ſome of the faireſt Roots in *February*, placing them at leaſt two Feet aſunder each Way, obſerving to keep the Ground clear from Weeds, until the *Turnips* have ſpread ſo as to cover the Ground, when they will prevent the Weeds from growing; and when the Pods are formed, you ſhould carefully guard them againſt the Birds, otherwiſe they will devour it, eſpecially when it is near ripe; at which Time you ſhould either ſhoot the Birds as they alight upon the Seed, or lay ſome birdlim'd Twigs upon it, whereby ſome of them will be caught; and if they are permitted to remain ſome Time, and afterwards turn'd looſe, they will prevent the Birds from coming there again for ſome Time, as I have experimented. When the Seed is ripe, it ſhould be cut up, and ſpread to dry in the Sun; after which it may be threſh'd out, and preſerv'd for Uſe.

RAPHANISTRUM; Charlock.

This differs from the *Radiſh*, in having a jointed Pod, containing one roundiſh Seed in each Joint.

There are ſeveral Varieties of this Plant, two of which grow wild in *England*; the others are Natives of *France*, *Spain* and *Italy*; but as they are Weeds which grow frequently on arable Land, ſo they are not cultivated in Gardens.

RAPHANUS; [of ῥᾴδιος, *eaſy*; and φαίνω, to *appear*; *q. d.* a *Plant eaſily appearing*; for this Plant being ſown, quickly puts forth out of the Ground] Radiſh.

The *Characters* are;

The Flower conſiſts of four Leaves, which are placed in form of a Croſs; out of the Flower-cup riſes the Pointal, which afterward turns to a Pod in form of a Horn, that is thick, ſpungy, and furniſhed with a double Row of roundiſh Seeds, which are ſeparated by a thin Membrane.

The *Species* are;

1. RAPHANUS *minor oblougus. C. B. P.* Small oblong *or* common Radiſh.

2. RAPHANUS *niger major rotundus. Mor. Hiſt.* Great, round, black Radiſh, *commonly called* The Spaniſh Radiſh.

3. RAPHANUS *major orbicularis, floribus candidis. C. B. P.* Great round-rooted Radiſh, with white Flowers.

4. RAPHANUS *minor oblongus pyriformis, vulgo Ramurazza. Hort. Cath.* The leſſer Radiſh, with an oblong Pear-ſhap'd Root.

5. RAPHANUS *major orbicularis, vel rotundus. C. B. P.* Greater Radiſh, with a round Root.

The firſt Sort here mentioned, is that which is commonly cultivated in Kitchen Gardens for its Root; of which there are ſeveral Varieties, as the Small-topp'd, the Deep-red, and the Long-topp'd ſtrip'd *Radiſh*; all which are Varieties ariſing from Culture: The Small-topp'd Sort is moſt commonly preferr'd by the Gardeners near *London*, becauſe they require much leſs Room than thoſe with large Tops, and may be left much cloſer together: And as the forward *Radiſhes* are what produce the greateſt Profit to the Gardener, ſo theſe being commonly ſown upon Borders near Hedges, Walls, or Pales, if they are of the Large-topp'd Sort, they will be apt to grow moſtly at Top, and not ſwell ſo much in the Root as the other, eſpecially if they are left pretty cloſe.

The Seaſons for ſowing this Seed are various, according to the Time when they are deſired for Uſe: But the earlieſt Seaſon is commonly toward the latter End of *October*, that the Gardeners near *London* ſow them to ſupply the Market; and theſe, if they do not miſcarry, will be fit for Uſe in *March* following, which is full as ſoon as moſt People care to eat them. Theſe (as I ſaid before) are commonly ſown on warm Borders, near Walls, Pales, or Hedges, where they may be defended from the cold Winds.

The ſecond Sowing is commonly about *Chriſtmas*, provided the Seaſon be mild, and the Ground in a fit Condition to work: Theſe are alſo ſow'd near Shelter, but not ſo near Pales or Hedges as the firſt Sowing: Theſe, if they are not deſtroy'd by Froſt, will be fit for Uſe the Beginning of *April*: But in order to have a Succeſſion of theſe Roots for the Table through the Seaſon, you ſhould repeat ſowing of their Seeds once a Fortnight, from the Middle of *January* till the Beginning of *April*, always obſerving to ſow the latter Crops upon a moiſt Soil, and an open Situation, otherwiſe they will run up, and grow ſticky, before they are fit for Uſe.

Many of the Gardeners near *London* ſow *Carrot* Seed with their early *Radiſhes*; ſo that many times when their *Radiſhes* are kill'd, the *Carrots* will remain; for the Seeds of *Carrots* commonly lie in the Ground five or ſix Weeks before they come up: and the *Radiſhes* ſeldom lie above a Fortnight under Ground; ſo that theſe are often up, and kill'd, when the *Carrot* Seed remains ſafe in the Ground: But when both Crops ſucceed, the *Radiſhes* muſt be drawn off very young, otherwiſe the *Carrots* will be drawn up ſo weak, as not to be able to ſupport themſelves when the *Radiſhes* are gone.

It is alſo a conſtant Practice with theſe Gardeners, to mix *Spinach* Seed with their latter Crop of *Radiſhes*; ſo that when the *Radiſhes* are drawn off, and the Ground clean'd between the *Spinach*, it will grow prodigiouſly, and in a Fortnight's Time will as completely cover the Ground, as tho' there had been no other Crop: And this *Spinach*, if it be of the broad-leav'd Kind, will be larger and fairer than it commonly is when ſown by itſelf; becauſe where People have no other Crop mix'd with it, they commonly ſow it too thick, whereby it is drawn up weak: But here the Roots ſtand pretty far apart, ſo that after the *Radiſhes* are gone, they have full Room to ſpread; and if the Soil be good, it is a prodigious Size this Spinach will grow to, before it runs up for Seed: But this Huſbandry is chiefly practis'd by the Gardeners, who pay very dear for their Land, and are oblig'd to have as many Crops in a Year as poſſible, otherwiſe they could not afford to pay ſuch large Rents.

When the *Radiſhes* are come up, and have got five or ſix Leaves, they muſt be pull'd up where they are too cloſe, otherwiſe they will draw up to Top, but the Roots will not increaſe their Bulk: In doing of this, ſome only draw them out by Hand: but the beſt Method is to hough them with a ſmall Hough, which will ſtir the Ground, and deſtroy the young Weeds, and alſo promote the Growth of the Plants. The Diſtance which theſe ſhould be left, if for drawing up ſmall, may be three Inches; but if they are to ſtand until they are pretty large, ſix Inches are full near enough; and a ſmall Spot of Ground will afford as many *Radiſhes* at each Sowing, as can be ſpent in a Family while they are good.

If you intend to ſave Seeds of your *Radiſhes*, you ſhould, about the Beginning of *May*, prepare a Spot of Ground in Proportion to the Quantity of Seeds intended (but you ſhould always make Allowance for bad Seaſons, becauſe it often happens, in a very dry Seaſon, that there will not be a fourth Part of the Quantity of Seeds upon the ſame Proportion of Ground as there will be in a moiſt Seaſon:) This Ground ſhould be well dug and levell'd; then you ſhould draw up ſome of the ſtraiteſt and beſt coloured *Radiſhes* (throwing away all ſuch as are ſhort, and that branch out in their Roots:) Theſe ſhould be planted in Rows three Feet Diſtance, and two Feet aſunder in the Rows, obſerving, if the Seaſon be dry, to water them until they have taken Root; after which they will require no farther Care, but only to hough down the Weeds between them, until they are advanced ſo high, as to ſpread over the Ground, when they will prevent the Growth of Weeds.

When the Seed begins to ripen, you ſhould carefully guard it againſt the Birds, who will otherwiſe deſtroy it: When it is ripe, (which you may know by the Pods changing brown) you ſhould cut it, and ſpread it in the Sun to dry; after which you ſhould threſh it out, and lay it up for Uſe, where the Mice cannot come to it, otherwiſe they will eat it up.

The ſmall round-rooted *Radiſh* is not very common in *England*; but in many Parts of *Italy* it is the only Sort cultivated. The Roots of this Kind are many times as large as a ſmall Turnip, and are very ſweet. This may be propagated in the ſame manner as the common Sort, but only with this Difference, *viz.* That this muſt not be ſown till the Beginning of *March*, and the Plants allow'd a greater Diſtance. The Seeds of this Kind are very ſubject to degenerate when ſav'd in *England*, ſo that it is proper to have them from abroad every Year.

The other round-rooted *Radiſhes* are rarely cultivated in *England*; but thoſe who have a mind to have them, may ſow them in the ſame manner as the laſt.

The *Black Spaniſh Radiſh* is only cultivated for Medicinal Uſe in *England*: The Seeds of this may be ſown in *May*; and when the Plants come up, they ſhould be houghed out, ſo as to leave the remaining ones ten Inches or a Foot aſunder; after which they muſt be conſtantly clear'd from Weeds in Summer, and in Autumn they will be fit for Uſe.

RAPISTRUM; Charlock, *or* Wild Muſtard.

There are two or three Species of this Plant, one of which grows wild in *England*, the other two are Weeds in the South of *France*, *Italy* and *Spain*. Theſe are never preſerv'd, except by Botaniſts for Variety.

RAPUNCULUS, Rampions.

The *Characters* are;

The Flower conſiſts of one Leaf, in its Form approaching to a Bell-ſhape; but is ſo expanded and cut, that it almoſt repreſents the Figure of a Star. The Pointal is commonly ſplit into two horned Diviſions, and the Flower-cup becomes a Fruit, which is divided into three Cells, incloſing many ſmall Seeds.

The *Species* are;

1. Rapunculus *ſpicatus. C. B. P.* Spiked Rampion.
2. Rapunculus *ſpicatus albus. C. B. P.* Spiked Rampion, with a white Flower.
3. Rapunculus *Alpinus corniculatus. C. B. P.* Horned Rampion of the *Alps*.
4. Rapunculus *ſcabioſæ capitulo cœruleo. C.B.P.* Rampions with blue ſcabious-like Heads.
5. Rapunculus *ſcabioſæ capitulo albo. C. B. P.* Rampion with white ſcabious-like Heads.
6. Rapunculus *ſpicatus, flore flaveſcente. Inſt. R. H.* Spiked Rampion, with a yellowiſh Flower.
7. Rapunculus *Creticus, ſeu pyramidalis altera. C. B. P.* Pyramidal Rampion of *Crete*.
8. Rapunculus *folio gramineo. Inſt. R. H.* Graſs-leaved Rampion.
9. Rapunculus *Creticus petromarula, flore albo. Tourn. Cor.* Rampion of *Crete*, with a white Flower.
10. Rapunculus *Orientalis, foliis anguſtis dentatis. Tourn. Cor.* Eaſtern Rampion, with narrow indented Leaves.
11. Rapunculus *Orientalis anguſtifolius multicaulis totus floridus. Tourn. Cor.* Eaſtern narrow leaved Rampion, with many Stalks, filled with Flowers.
12. Rapunculus *Orientalis, campanulæ pratenſis folio. Tourn. Cor.* Eaſtern Rampion, with a meadow Belflower-leaf.
13. Rapunculus *Orientalis, foliis longioribus, aſperis & rigidis. Tourn. Cor.* Eaſtern Rampion, with longer rough ſtiff Leaves.
14. Rapunculus *Orientalis altiſſimus, foliis glabris & rigidis. Tourn. Cor.* The talleſt Eaſtern Rampion, with ſmooth ſtiff Leaves.
15. Rapunculus *Orientalis, heſperidis folio. Tourn. Cor.* Eaſtern Rampion, with a Dames-violet-leaf.

Theſe are all of them hardy Plants, which will thrive in the open Air: they are propagated by Seed, which ſhould be ſown in Autumn; for if they are kept out of the Ground till the Spring, they frequently fail. Theſe Seeds ſhould be ſown on a Bed of freſh undunged Earth, where they are deſigned to remain; for they do not thrive ſo well when they are tranſplanted. Therefore the beſt Method is, to make ſmall Drills croſs the Bed, about eighteen Inches aſunder, and ſow the Seeds therein: then cover them lightly over with Earth; for if they are buried too deep, they will rot in the Ground. In about a Month after the Seeds are ſown, the Plants will come up; when they ſhould be diligently weeded, which is all the Care they will require till Spring; at which Time the Plants ſhould be thinned where they are too cloſe; ſo as to leave them ſix or ſeven Inches apart in the Rows; and afterwards they require no farther attention but to keep them clear from Weeds. In *June* the Plants will flower, and if the Summer prove favourable, they will produce ripe Seeds.

As theſe Plants do not continue above two or three Years, ſo there ſhould be Seeds ſown every other Year, to continue the Sorts; for they are Plants which require little Trouble to cultivate them, and their Flowers make a pretty Variety in large Gardens; therefore they ſhould be allowed a Place amongſt other hardy Flowers.

RAPUNTIUM; Rampions, *or* Cardinal's Flower.

The *Characters* are;

The Flower conſiſts of one Leaf, which is of an anomalous Figure, hollowed like a Pipe, and furrow'd or channell'd, divided, as it were, into many Parts, in the Shape of a Tongue, defended by a Vagina or Covering, which enfolds the Pointal: When the Flowers decay, the Flower-cup turns to a Fruit, divided into three Cells, full of ſmall Seeds, which adhere to a Placenta, which is divided into three Parts.

The *Species* are;

1. Rapuntium *maximum, coccineo ſpicato flore. Col. in Reçh.* Greater Rampions, with a Crimſon-ſpiked Flower, *commonly call'd* The Scarlet Cardinal's Flower.

3. Rapuntium *Americanum, flore dilute cœruleo H. R. Par.* The Blue Cardinal's Flower.

3. Rapuntium *Americanum, virgæ aureæ foliis, parvo flore cœruleo. Tourn.* Cardinal's Flower, with Golden Rod Leaves, and a ſmall Blue Flower.

There are ſeveral other Varieties of this Plant growing in divers Parts of *America*; but thoſe here mentioned are all which I have obſerv'd cultivated in *England*. The firſt Sort is greatly prized by the Curious for the Beauty of its rich Crimſon Flowers, which exceed all the Flowers I have yet ſeen, in the Deepneſs of its Colour: And theſe commonly, when their Roots are ſtrong, produce large Spikes of theſe Flowers, which continue a long Time in Beauty, and make a moſt magnificent Shew amongſt other Flowers. The Time of their Flowering is commonly in *July* and *Auguſt*; and if the *Autumn* proves very favourable, they will ſometimes produce good Seeds in *England*. Theſe Plants are Natives of *Virginia* and *Carolina*, where they grow by the Sides of Rivulets, and make a moſt beautiful Appearance; from whence the Seeds are often ſent into *England*. Theſe Seeds do commonly arrive here in the Spring; at which Time they ſhould be ſown in Pots fill'd with light Earth, and but juſt cover'd over; for if the Seeds are buried deep, they will not grow: Theſe Pots ſhould be placed under a Frame, to defend them from Cold, until the Seaſon is a little advanc'd; but they ſhould not be plac'd on a Hot-bed, which will alſo deſtroy the Seeds.

When the Weather is warm, towards the Middle of *April*, theſe Pots ſhould be placed in the open Air, in a Situation where they may have the Morning Sun till twelve of the Clock, obſerving to water them conſtantly in dry Weather; and when the Plants come up, they ſhould be tranſplanted each into a ſmall Pot fill'd with freſh light Earth, and plac'd in the ſame Situation, obſerving to water them in dry Weather; and in Winter they ſhould be plac'd under a Hot-bed Frame, where they may be ſhelter'd from ſevere Froſts;

but in mild Weather they ſhould be as much expos'd to the open Air as poſſible.

The *March* following theſe Plants ſhould be put into larger Pots fill'd with the ſame freſh Earth, and plac'd, as before, to the Morning Sun, obſerving to water them in dry Weather, which will cauſe them to flower ſtrong the *Autumn* following.

Theſe Plants are alſo propagated by parting of their Roots: The beſt Seaſon for which is, either ſoon after they are paſt Flower, or in *March*, obſerving to water and manage them, as hath been directed for the Seedling Plants, both in *Winter* and *Summer*.

The Blue Sort does conſtantly produce ripe Seeds in *England*, which ſhould be ſown ſoon after they are ripe; in the *Spring* following the Plants will come, when they ſhould be tranſplanted and managed as the other Sort, with which Culture this will alſo agree. This is preſerv'd for Variety; but the Flowers are not near ſo beautiful as thoſe of the former Sorts.

The other Sort, with ſmall Blue Flowers, is a biennial Plant, periſhing as ſoon as the Seeds are ripe. This may be raiſed in the ſame Manner as the former, but is ſcarcely worthy of a Place in the Flower Garden.

To this *Article* muſt be added;

1. Rapuntium *Americanum, floribus albis. Inſt. R. H. American* Cardinal Flower, with white Flowers.

2. Rapuntium *Americanum, coccineo flore, lineis albis eleganter picto. Inſt. R. H. American* Cardinal Flower, with a ſcarlet Flower, elegantly ſtriped with White.

3. Rapuntium *Americanum altiſſimum, foliis cirſii, flore vireſcente. Plum. Cat.* The talleſt *American* Cardinal Flower, with Leaves like the Melancholy-thiſtle, and greeniſh Flowers.

4. Rapuntium *Americanum, foliis cirſii lucidis, flore multiplici coccineo conglobato. Plum. Cat. American* Cardinal Flower, with ſhining melancholy-thiſtle Leaves, and many ſcarlet Flowers growing in Cluſters.

5. Rapuntium *Americanum, trachelii folio, flore purpuraſcente. Plum. Cat. American* Cardinal Flower, with a throatwort Leaf, and a purpliſh Flower.

6. Rapuntium *Americanum, foliis oblongis, floribus parvis cæruleis, ſpicâ longiſſimâ. American* Cardinal Flower, with oblong Leaves, and ſmall blue Flowers, growing in a long Spike.

7. Rapuntium *urens Solonienſe. Mor. H. R. Blæſ.* Burning Cardinal Flower of *Blois*.

8. Rapuntium *urens, flore purpureo-cæruleo. Inſt. R. H.* Burning Cardinal Flower, with a blueiſh purple Flower.

9. Rapuntium *Africanum minus anguſtifolium, flore violaceo. Inſt. R. H.* Leſſer narrow-leaved *African* Cardinal Flower, with a violet-coloured Flower.

10. Rapuntium *Æthiopicum, violaceo galeato flore, foliis pinaſtri. Breyn. Cent. Ethiopian* Cardinal Flower, with a violet galeated Flower, and leaves like the Pinaſter.

11. Rapuntium *Æthiopicum, cæruleo galeato flore, foliis coronopi. Breyn. Cent. Ethiopian* Cardinal Flower, with a blue galeated Flower, and Leaves like Buckshorn Plantain.

12. Rapuntium *Æthiopicum, cæruleo galeato flore, foliis dentatis. Breyn. Cent. Ethiopian* Cardinal Flower, with a blue galeated Flower, and indented Leaves.

13. Rapuntium *Canadenſe pumilum, linariæ folio. Sarrac.* Low *Canady* Cardinal Flower, with a toad-flax Leaf.

14. Rapuntium *Creticum minimum, bellidis folio, flore maculato. Tourn. Cor.* The leaſt Cardinal Flower of *Crete*, with a daizy Leaf, and a ſpotted Flower.

Moſt of theſe Sorts are biennial Plants, which commonly periſh when they have produced Seed; ſo ſhould be ſown every Year, in order to continue a Succeſſion of them to flower annually. The fifth Sort is an annual Plant, which flowers and ſeeds the ſame *Summer* it is ſown, and ſoon after periſhes. If the Seeds of this Kind are permitted to ſcatter in the Pots, and the Pots kept in the Stove, the Plants will come up in *Autumn*, and flower early the following *Spring*.

The Seeds of the other Sorts ſhould be ſown in Pots filled with light rich Earth, and plunged into a moderate Hot-bed of Tanners-bark, and ſhould be frequently watered; otherwiſe the Seeds will remain in the Earth ſeveral Months, before the Plants will appear; and ſometimes I have known the Seeds remain in the Earth a whole Year, and the Plants have come up the following *Spring*. When the Plants come up, they ſhould be tranſplanted each into a ſeparate ſmall Pot, and plunged into the Hot-bed again to bring them forward; but in *June* they ſhould be inured to bear the open Air by degrees, and toward the End of that Month, they may be removed out of the Hot-bed, and placed in a warm Situation, where they may have the Morning Sun, and muſt be conſtantly watered in dry Weather. In this Place they may remain till *October*, when they ſhould be placed under a common Hot-bed Frame, where they ſhould have as much free Air as poſſible in mild Weather; but muſt be covered in froſty Weather, otherwiſe they will not live in this Country. The *Spring* following the Plants muſt be ſhifted into larger Pots, and placed abroad again in a ſheltered Situation, and duly watered, otherwiſe they will not flower very ſtrong. In *July* the Plants will produce their Flowers, and if the *Autumn* proves favourable, they will perfect their Seeds.

RAUVOLFIA.

The *Characters* are;

It hath a tubulous Flower conſiſting of one Leaf, whoſe upper Part ſpreads open into a plain Surface, and is cut into ſeveral Parts; from whoſe Cup ariſes the Pointal, fixed like a Nail, which afterward becomes an almoſt globular ſoft Fruit, full of Milk, in which are contained one or two hard Seeds.

The *Species* are;

1. Rauvolfia *tetraphylla anguſtifolia. Plum. Nov. Gen.* Four-leaved *Rauvolfia*, with narrow Leaves.

2. Rauvolfia *tetraphylla latifolia. Plum. Nov. Gen.* Four leaved *Rauvolfia*, with broad Leaves.

This Name was given to this Genus of Plants by Father *Plumier*, who was the Perſon that diſcovered them in *America*, in Honour to *Leonard Ravwolf*, who was a curious Botaniſt, and flouriſhed about the Year 1583. He travelled into the *Holy-land*, and ſeveral other Places in the Eaſt, and publiſhed his Travels in *High-Dutch*, which were tranſlated into *Engliſh* under the Inſpection of the great Mr. *Ray*.

Theſe Plants grow plentifully at *Campechy*, from whence I received their Seeds, which were collected by Mr. *Robert Millar*, Surgeon.

The Seeds of theſe Plants ſhould be ſown in Pots filled with freſh Earth, and plunged into a Hot-bed of Tanners-bark; for as they are very hard, ſo they frequently remain a long time in the Ground: therefore when they are in Pots, they may be ſhifted from one Bed to another, as their Heat decays. When the Plants come up, they muſt be frequently refreſhed with Water, but it muſt not be given them in large Quantities; for the Plants are ſucculent, and full of a milky Juice, ſo are in Danger of rotting with too much Moiſture. They ſhould alſo have a large Share of freſh Air admitted to them in warm Weather; and when they are about two Inches high, they ſhould be tranſplanted each into a ſeparate ſmall Pot, filled with freſh light Earth, and then plunged into the Hot-bed again; obſerving to ſhade them from the Sun, until they have taken new Root; after which Time they ſhould have free Air admitted to them every Day, in proportion to the Warmth of the Seaſon, and they muſt be often refreſhed with Water. In this Hot-bed the Plants may remain till toward *Michaelmas*, when they ſhould be removed into the Stove, and plunged into the Tanners-bark, where they muſt be kept warm, and not have too much Moiſture in cold Weather, leſt it rot them.

As theſe Plants are Natives of very hot Countries, ſo they will not live in the open Air in *England*; therefore they ſhould conſtantly remain in the Stove; and if they remain in the Bark-bed, they will thrive much faſter, than when they are placed on Stands in a dry Stove. But in the *Summer* Seaſon, they ſhould have a large Share of freſh Air admitted to them, and the Leaves of the Plants muſt be now and then waſhed with a Sponge, to clear them from the Filth they are apt to contract, which, if ſuffered to remain, will retard the Growth of the Plants. Where this Care is taken of them, they will thrive very faſt, and the ſecond Year will produce Flowers, and continue ſo to do for many Years; but as yet they have not perfected their Seeds in *England*. They may alſo be propagated by Cuttings, which ſhould be laid to dry for two or three Days before they are planted; and then ſhould be plunged into a moderate Hot-bed of Tanners-bark, obſerving to ſhade them until they have taken Root; after which Time they may be treated as the ſeedling Plants.

RESEDA, Baſtard-rocket.

The *Characters* are;

It hath a polypetalous anomalous Flower, compoſed of ſeveral diſſimilar Petals, out of whoſe Cup ariſes the Pointal, which afterward becomes a membranaceous Fruit, for the moſt part three

three or four-cornered, oblong, and, as it were cylindraceous, pregnant with roundiſh Seeds.

The *Species* are;

1. RESEDA *vulgaris. C. B. P.* Common Baſtard-rocket.
2. RESEDA *criſpa Gallica. Bocc. Rar. Pl.* Curled *French* Baſtard-rocket.
3. RESEDA *latifolia, flore flavo. Mor. Hiſt.* Broad-leaved Baſtard-rocket, with a yellow Flower.
4. RESEDA *foliis calcitrapæ, flore albo. Mor. H. R. Blæſ.* Baſtard-rocket, with Star-thiſtle-leaves, and a white Flower.
5. RESEDA *minor vulgaris. Inſt. R. H.* Smaller common Baſtard-rocket.
6. RESEDA *minor vulgaris, folio minus inciſo. Inſt. R. H.* Smaller common Baſtard-rocket, with a Leaf leſs cut.
7. RESEDA *minor vulgaris, foliis integris. Inſt. R. H.* Small common Baſtard-rocket, with whole Leaves.
8. RESEDA *Pyrenaica, linariæ folio glauco. Schol. Bot. Pyrenean* Baſtard-rocket, with a glaucous toad-flax Leaf.

Theſe Plants are preſerved in the Gardens of ſome Perſons, who are curious in Botany; but at preſent they are not uſed in Medicine. They are all of them very hardy Plants, which are propagated by Seeds, which ſhould be ſown in the Spring, on an open Bed of freſh undunged Earth, in the Place where they are deſigned to remain; and when the Plants come up, they ſhould be houghed to ſeparate them, where they are too cloſe, as alſo to deſtroy the Weeds. The four firſt Sorts ſhould be allowed eighteen Inches or two Feet; but the other Sorts, being of leſs Growth, do not require above half that Room. The Weeds ſhould be conſtantly houghed down between the Plants when they ariſe, which is all the Culture the Plants require. Some of theſe Plants will flower the ſame Year they are ſown, when they come up early in the Spring; but in general they do not flower till the ſecond Year, when they produce their Seeds, and the Plants commonly periſh ſoon after. If the Seeds of theſe Plants are permitted to ſcatter, the Plants will come up, and ſtock the Ground, ſo as to become Weeds.

RHABARBARUM MONACHORUM; *vide* Lapathum.

RHAMNOIDES; The Sea Buckthorn.

The *Characters* are;

It hath the whole Appearance of the Buck-thorn, *but is Male and Female in different Trees: The Flowers of the Male have no Petals; the Flower-cup conſiſts of two Leaves, in the Centre of which are ſeveral ſmall Stamina: The Female Trees produce roundiſh Berries, each of which contains a ſingle Seed.*

The *Species* are;

1. RHAMNOIDES *florifera, ſalicis foliis. T. Cor.* Male Willow-leav'd Sea Buckthorn.
2. RHAMNOIDES *fructifera, foliis ſalicis, baccis leviter flaveſcentibus. T. Cor.* Female Willow-leav'd Sea Buckthorn, with yellow Berries.

Theſe Plants do grow in great Plenty upon the Sea-coaſts of *Lincolnſhire*, and at *Sandwich*, *Deal* and *Folkſton* in *Kent*, as alſo in divers Parts of *Scotland*.

They are preſerv'd in ſeveral Gardens near *London* for Variety; where, being intermixed with other Shrubs of the ſame Growth, they afford an agreeable Proſpect.

Theſe Shrubs are eaſily propagated from Suckers, which they ſend forth in great Plenty from the old Plants. Theſe Suckers may be taken off any time in *February* or *March*, and planted in a Nurſery, where they may be train'd up for two or three Years; after which they may be remov'd to the Places where they are to remain. There is no very great Beauty in theſe Plants; but as their Leaves and Flowers are very different from moſt other Trees, ſo they make a pretty Variety in ſmall Wilderneſs Quarters; or when planted in Clumps with various Trees, they will grow to be ten or twelve Feet high, but it is very rare to ſee them larger.

RHAMNUS; The Buckthorn.

The *Characters* are;

It hath a Funnel-ſhap'd Flower, conſiſting of one Leaf, which is divided towards the Top into four or five Segments; out of the Flower-cup riſes the Pointal, which afterward becomes a ſoft roundiſh Berry, very full of Juice, incloſing four hard Seeds, which are round and ſmooth on the Outſide, but flatted on the other.

The *Species* are;

1. RHAMNUS *catharticus. C. B. P.* Common purging Buckthorn.
2. RHAMNUS *catharticus minor. C. B. P.* Leſſer purging Buckthorn.
3. RHAMNUS *Afer, folio pruni longiori ſubrotundo, flore candicante, ſpinis longiſſimis. Boerh. Ind. alt.* African Buckthorn, with a longer roundiſh Plum Leaf, white Flowers, and very long Spines.
4. RHAMNUS *Hiſpanicus, folio buxi, minor. Tourn.* Leſſer Spaniſh Buckthorn, with a Box Leaf.
5. RHAMNUS *catharticus minor, folio longiori. Inſt. R. H.* Leſſer purging Buckthorn, with a longer Leaf.
6. RHAMNUS *tertius, flore herbaceo, baccis nigris. C.B.P. Cluſius*'s third Buckthorn, with an herbaceous Flower, and black Berries.
7. RHAMNUS *Hiſpanicus, buxi folio ampliore. Inſt. R. H. Spaniſh* Buckthorn, with a larger Box-leaf.
8. RHAMNUS *Hiſpanicus, oleæ folio. Inſt. R. H. Spaniſh* Buckthorn, with an Olive-leaf.
9. RHAMNUS *Hiſpanicus, hyperici folio. Inſt. R. H. Spaniſh* Buckthorn, with a St. Johns-wort Leaf.
10. RHAMNUS *Creticus, amygdali folio minori. Tourn. Cor. Candy* Buckthorn, with a ſmaller almond Leaf.
11. RHAMNUS *Orientalis, alaterni folio. Tourn. Cor.* Eaſt-Buckthorn, with an alaternus Leaf.
12. RHAMNUS *Creticus, buxi folio minori. Tourn. Cor. Candy* Buckthorn, with a ſmaller box-tree Leaf.
13. RHAMNUS *Orientalis, amygdali folio ampliore. Tourn. Cor.* Eaſtern Buckthorn, with a larger almond Leaf.

The firſt of theſe Trees is very common in the Hedges in divers Parts of *England*; the Berries of which are order'd by the *College of Phyſicians* for Medicinal Uſe; but particularly for making a Syrup, which was formerly in great Uſe, but of late the Perſons who ſupply the Markets with theſe Berries, have gathered ſeveral other Sorts of Berries, which they have either mixed with thoſe of the *Buckthorn*, or have wholly ſubſtituted them in their Place; theſe are the Berries of the *Frangula*, *Cornus Fœmina*, *&c.* which Mixture hath ſpoiled the Syrup, and render'd it leſs eſteem'd. But whoever purchaſes the *Buckthorn* Berries, may diſtinguiſh whether they are right or not, by opening them, and obſerving the Number of Seeds in each; for theſe have commonly four, whereas the *Frangula* has but two, and the *Cornus Fœmina* but one; as alſo by bruiſing of the Berries on white Paper, the Juice giving a green Tincture.

The ſecond Sort is leſs common in *England*, and only to be found in Gardens, where it is cultivated for Variety. Both theſe Sorts may be propagated by laying down their tender Branches in *Autumn*, which, if duly water'd in dry Weather the ſucceeding *Summer*, will take Root in the Compaſs of one Year, and may then be tranſplanted either where they are to remain, or in ſome Nurſery, to be train'd up for a few Years, and then remov'd to their Places of Growth.

The firſt Sort will grow to the Height of eighteen or twenty Feet; but being a ſtraggling Grower, is ſeldom much cultivated in Gardens.

The ſecond Sort ſeldom riſes above five Feet high, and ſo ſhould be planted amongſt Shrubs of the ſame Growth, where it will add to the Variety, tho' it has little more Beauty than the former.

They may alſo be propagated by Seeds, which muſt be ſown on a Bed of freſh Earth, ſoon after they are ripe; the Spring following the Plants will appear, when they muſt be carefully clean'd from Weeds; the *Autumn* following they may be tranſplanted out, and managed as the Layers.

The fourth Sort is alſo preſerv'd in ſeveral curious Gardens for Variety: this produces vaſt Quantities of purple Flowers, moſt part of *Summer*, and many times ripens its Seeds in *England*: This may be propagated by laying down the tender Branches in the *Spring*, which will take Root by the *Spring* following, when they ſhould be planted into Pots; and require to be houſed in *Winter*, tho' they need only be ſhelter'd from the extreme Froſt; but ſhould have as much free Air as poſſible in mild Weather, and in *Summer* muſt be often water'd. It delights in a freſh light Soil, and requires to be often remov'd, becauſe the Roots do greatly increaſe, ſo as to fill the Pots in a ſhort Time.

The nine laſt Plants are Natives of warmer Countries than *England*; but yet they are hardy enough to thrive in the open Air very well, if they are planted in ſheltered Situations: and as they are Shrubs of moderate Growth, ſo they may be admitted to have a Place in Wilderneſs Quarters, where they will live under taller Trees, and add to the Variety.

They may be propagated either by Seeds, which ſhould be ſown ſoon after they are ripe; or by laying down of the tender Branches, in the ſame manner as above directed for the common Sort.

But if theſe Plants are raiſed from Seeds, they will require a little Care the firſt *Winter*, if the Froſt ſhould prove ſevere; in which Caſe there ſhould be ſome dry Fern or Oak Branches with their Leaves on, laid over them; which will protect them from the Froſt, and at the ſame Time admit Air to the Plants; to prevent their growing mouldy; which oftentimes deſtroys the tender Parts of Plants, when the Air is too much excluded from them.

The fifth Sort here enumerated ſeldom riſes above four or five Feet high; but moſt of the other Sorts will grow to the Height of ten or twelve Feet, and divide into many Branches, ſo as to form large Shrubs; and being different in their Leaves from each other, they make an agreeable Variety; for which reaſon they are preſerved by ſuch Perſons as delight in hardy Trees and Shrubs.

RHUS; [ῥοῦς takes it Name of ῥέω to *flow*, becauſe it ſtops dyſenterial Fluxes of the Belly, and Womens Courſes] The Sumach Tree.

The *Characters* are;

The Flower conſiſts of five Leaves, which are placed in a circular Order, and expand in form of a Roſe; from whoſe Flower-cup riſes the Pointal, which afterwards becomes a roundiſh or almoſt Kidney-ſhaped Veſſel, containing one Seed of the ſame Shape: To which marks may be added, the Flowers growing in Bunches, and the Leaves are either winged, or have three Lobes.

The *Species are*;

1. RHUS *Virginianum. C. B. P.* Virginian Sumach, *by ſome falſely call'd* The Stag's horn Tree.
2. RHUS *tenuifolia Virginiana humilis: Rhus anguſtifolium. C. B. P. Pluk. Alm.* Dwarf Virginian Sumach with narrow Leaves.
3. RHUS *Africanum trifoliatum majus, foliis ſubtus argenteis acutis, & margine inciſis. Pluk. Phyt.* Great African three-leav'd Sumach, with narrow Leaves cut on their Edges, and white underneath.
4. RHUS *Africanum trifoliatum minus glabrum, ſplendente folio ſubrotundo integro, forte Lentiſcus Africanus triphyllos quorundam. Pluk. Phyt.* Leſſer three-leav'd African Sumach, with a whole, roundiſh, ſhining, ſmooth Leaf.
5. RHUS *Africanum trifoliatum majus, folio ſubrotundo integro, molli & incano. Pluk. Phyt.* Greater three-leav'd African Sumach, with a whole, roundiſh, woolly Leaf.
6. RHUS *Americanum, paniculâ ſparſâ herbaceâ, ramis patulis glabris. Horth. Elth. American* Sumach, with a looſe herbaceous Panicle, and low ſmooth Branches.
7. RHUS *folio ulmi. C. B. P.* Elm-leaved Sumach.

The firſt of theſe Plants is pretty common in many Gardens near *London*, where it endures the ſevereſt Cold of the *Winters* in the open Air, and is uſually intermixed in ſmall Wilderneſs Quarters, amongſt other Trees of the like Growth, where it affords an agreeable Variety: This produces Bunches of ſmall Flowers in *June*, at the Extremities of the Branches, which are ſucceeded by Seeds which are incloſed in red Covers, ſo that the whole Spikes appear of a fine red Colour. Theſe Bunches are ſometimes uſed in Dying, and the Branches of the Tree are uſed for Tanning of Leather in *America*, where theſe Trees grow in Plenty.

This Tree will grow to be eight or ten Feet high, but is very ſubject to produce crooked, unſightly Branches, ſo that it can't be reduc'd to a regular Stem, which renders it unfit to plant ſingly in an open Situation: but amongſt other Trees, where the Deformity of the Stem is hid, it looks very well.

The ſecond Sort is leſs common than the firſt, and only to be found in ſome very curious Gardens. This is like the firſt, in moſt reſpects, but is of much ſmaller Growth, and the Leaves are very narrow. Both theſe may be propagated in Plenty, from the great Quantity of Suckers which they produce from their Roots, which being taken off in *March*, and planted on a light ſandy Soil, will, in a few Years, produce Flowers. They may alſo be propagated by laying down of the Branches, in the *Spring* of the Year, which will take Root in the Compaſs of one Seaſon, and may then be taken off and tranſplanted where they are to remain.

The *African* Sorts are all preſerv'd in Pots or Tubs, and houſed in *Winter*, being too tender to endure the Cold of this Climate in the open Air. Theſe may be propagated by laying down their young Branches into freſh Earth, obſerving to water them duly in dry Weather, which will greatly forward their Rooting: In one Year they will be fit to tranſplant, when they may be taken from the old Plants, and each placed in a ſeparate Pot, fill'd with freſh light Earth. The beſt Time for tranſplanting of theſe Plants, is in *April*, obſerving to water and ſhade them until they have taken Root; after which they may be expos'd with Myrtles, Oleanders, and other hardy Exoticks, during the *Summer* Seaſon, and in *Winter* muſt be houſed with them, being equally as hardy, and only require to be ſcreened from ſevere Froſt.

Theſe Plants do rarely produce Flowers in *England*; but as they retain their Leaves all the *Winter*, and may eaſily be reduced to a regular Head, ſo they are preſerved for the Diverſity of their Leaves, which adds to the Variety of a Green Houſe.

The ſixth Plant was brought from *North Carolina*, and I have ſince received the Seeds of this Kind from *Penſilvania*, where it grows in great Plenty. This Sort doth not grow very large, being ſeldom above ſix or eight Feet high; but divides into ſeveral Branches, which grow more regular than moſt of the other Sorts; and the Flowers are produced on the Tops of the Branches, which are in very large looſe Panicles, and of a yellowiſh green Colour. The tender Shoots of this Plant are of a purpliſh Colour, and ſmooth; and the Leaves are ſmooth, having a great Number of *Pinnæ* on each.

The ſeventh Sort grows plentifully in the South of *France*, and in *Spain*; but is at preſent pretty rare in *England*. This Sort is directed by the College of Phyſicians to be uſed in Medicine; and in the South of *France*, it is uſed inſtead of Oak-bark for tanning of Leather.

Theſe two laſt Sorts are very hardy Plants, which will live in the open Air in *England*, and are very proper to plant with other hardy Shrubs in Quarters of Wilderneſs-work, where they will make an agreeable Variety. Theſe may be propagated by Seeds, or from Suckers or Layers, after the ſame manner as hath been directed for the common *Virginian Sumach.*

RIBES; The Currant-Tree.

The *Characters* are;

It hath no Prickles; the Leaves are large; the Flower conſiſts only of five Leaves, which are placed in a circular Order, and do expand in form of a Roſe; the Ovary, which ariſes from the Center of the Flower-cup, becomes a globular Fruit, which are produced in Bunches.

The *Species* are;

1. RIBES *vulgaris acidus ruber. J. B.* Common red Currant.
2. RIBES *major, fructu rubro. H. Eyſt.* The large Dutch red Currant.
3. RIBES *vulgaris acidus albas baccas ferens. J. B.* Common white Currant.
4. RIBES *quæ groſſularia hortenſis, majore fructu albo. H. R. Par.* Large Dutch white Currant.
5. RIBES *major, fructu carneo.* The Champaign Currant, *vulgo.*
6. RIBES *Alpinus dulcis. J. B.* The Gooſeberry-leav'd Currant.
7. RIBES *fructu parvo. Merr. Pin.* The ſmall wild Currant.
8. RIBES *nigrum vulgo dictum, folio olente. J. B.* The black Currant.
9. RIBES *vulgaris, foliis ex luteo variegatis.* The yellow ſtrip'd-leav'd Currant.
10. RIBES *vulgaris, foliis ex albo eleganter variegatis.* The common Currant, with Leaves beautifully variegated with Green and White.
11. RIBES *fructu albo, foliis ex albo variegatis.* The white Currant, with ſtrip'd Leaves.
12. RIBES *Alpinus dulcis, foliis variegatis.* The ſtrip'd Gooſeberry-leav'd Currant.
13. RIBES *fructu nigro, foliis variegatis.* The black Currant, with ſtrip'd Leaves.
14. RIBES *Americanus, fructu nigro.* The American black Currant.

The five firſt mentioned Sorts are preſerv'd in all curiou Gardens for the ſake of their Fruits: Indeed, of late Years the common red and white Currants have been neglected, ſince the *Dutch* red and white have become plenty in *England*

land; theſe producing much larger and fairer Fruit to the Sight than the common Sorts, tho' I think the common Sorts are much better flavour'd, ſo that they ſhould not be intirely neglected by ſuch as are curious in Fruits.

The ſixth Sort is preſerv'd as a Curioſity, by ſuch who delight in Variety; but the Fruit is not valuable.

The ſeventh Sort is found wild in *England*. The Fruit of this Kind is ſmall, and very tart, which renders it unworthy of being cultivated in Gardens.

The eighth Sort is preſerved in ſome old Gardens; but the Fruit having a diſagreeable ſtrong Taſte, has occaſioned its being but little cultivated of late Years.

Thoſe Sorts with variegated Leaves, are preſerved by ſuch as are fond of ſtrip'd Plants; but as their greateſt Beauty is only in the *Spring*, before their Leaves grow large, after which they become more green; ſo they are ſcarcely worth preſerving in a Garden.

The fourteenth Sort was obtain'd by Mr. *Peter Colliſon* from *America*, in whoſe fine Garden it has produced Fruit, and from thence hath been communicated to ſeveral other curious Gardens. The Manner of this Plant's Flowering is very different from the other Sorts of Currants, for which Variety it may have a Place amongſt other Shrubs; but the Fruit being ſomewhat like our black Currant, is not much eſteem'd.

All theſe Sorts may be eaſily propagated by planting their Cuttings any time from *September* to *March*, upon a Spot of freſh Earth, which in the *Spring* muſt be kept very clear from Weeds, and in very dry Weather if they are water'd, it will greatly promote their Growth: Theſe may remain two Years in this Nurſery, during which Time they muſt be pruned up for the purpoſes deſigned, *i. e.* either to clear Stems, if for Standards, or if for Walls, Pales, or Eſpaliers, they may be trained up flat.

Then they ſhould be planted out where they are to remain; the beſt Seaſon for which is ſoon after the Leaves begin to decay, that they may take Root before *Winter*, ſo that they may be in no Danger of ſuffering from Drought in the *Spring*.

Theſe Plants are generally planted in Rows at about ten Feet aſunder, and four Diſtance in the Rows; but the beſt Method is to train them againſt low Eſpaliers, in which manner they will take up much leſs Room in a Garden, and their Fruit will be much fairer.

The Diſtance they ſhould be placed for an Eſpalier, ought not to be leſs than eight Feet, that their Branches may be trained horizontally, which is of great Importance to their Bearing.

Thoſe that are planted againſt Pales or Walls, ſhould alſo be allowed the ſame Diſtance; if they are planted againſt a South-Eaſt Wall or Pale, it will cauſe their Fruit to ripen at leaſt a Fortnight or three Weeks ſooner than thoſe in the open Air, and thoſe which are planted againſt a North Wall or Pale, will be proportionably later; ſo that by this Method the Fruit may be continued a long Time in Perfection, eſpecially if thoſe againſt the North Pales are matted in the Heat of the Day.

Theſe Plants produce their Fruit upon the former Year's Wood, and alſo upon ſmall Snags which come out of the old Wood, ſo that in pruning them, theſe Snags ſhould be preſerved, and the young Shoots ſhortened in Proportion to their Strength. The only Method, very neceſſary to be obſerved in pruning of them, is not to lay the Shoots too cloſe, and never to prune their Snags to make them ſmooth: this, with a ſmall Care in obſerving the Manner of their Growth, will be ſufficient to inſtruct any Perſon how to manage this Plant, ſo as to produce great Quantities of Fruit.

Theſe Plants will thrive and produce Fruit in almoſt any Soil or Situation, and are often planted under the Shade of Trees; but the Fruit is always beſt when they are planted in the open Air, and upon a dry Soil.

RICINOIDES; Phyſick-nut, *vulgo*.

The *Characters* are;

The Male Flowers conſiſt of ſeveral Leaves, which are placed in a circular Order, and do expand in form of a Roſe; theſe are barren: At remote Diſtances from theſe Flowers, upon the ſame Plant, are produced the Embryo's, which are wrapt up in the Flower cup, and afterwards do become tricapſular Fruits, containing one oblong Seed in each Cell.

The *Species* are;

1. RICINOIDES *Americana, goſſypii folio. Tourn.* American Phyſick-nut, with a Cotton Leaf.

2. RICINOIDES *arbor Americana, folio multifido. Tourn.* Tree American Phyſick-nut, with a multifid Leaf, *commonly called in the* Weſt-Indies, French Phyſick-nut.

3. RICINOIDES *Americana, ſtaphyſagriæ folio. Tourn.* American Phyſick-nut, with a Staves-acre Leaf, *called in the* Weſt-Indies, Bellyach-weed and Wild Caſada.

4. RICINOIDES *Americana, oleaſti folio. Plum.* American Phyſick nut, with a wild Olive Leaf.

5. RICINOIDES *fruteſcens, althϾ folio. Plum. Cat.* Shrubby Phyſick-nut, with a Marſhmallow Leaf.

6. RICINOIDES *foliis populi hirſutis. Plum. Cat.* Phyſick-nut, with hairy Poplar Leaves.

7. RICINOIDES *fruteſcens, linariæ foliis obtuſis. Plum. Cat.* Shrubby Phyſick-nut, with blunt Toad-flax Leaves.

8. RICINOIDES *folio citrii, argenteo polline conſperſo. Plum. Cat.* Phyſick-nut, with a Citron Leaf, powder'd over with Silver.

9. RICINOIDES *elæagni folio. Plum. Cat.* Phyſick-nut, with a Wild-olive Leaf.

10. RICINOIDES *verbaſci folio. Plum. Cat.* Phyſick-nut, with a Mullein Leaf.

11. RICINOIDES *caſtaneæ folio. Plum. Cat.* Phyſick-nut, with a Cheſnut Leaf.

12. RICINOIDES *herbaceum, foliis trifidis vel quinquefidis & ſerratis. Houſt.* Herbaceous Phyſick-nut, with three or five-ſawed Leaves.

13. RICINOIDES *folio ſubrotundo ſerrato, fructu parvo conglomerato. Houſt.* Phyſick-nut, with a roundiſh-ſawed Leaf, and ſmall Fruit, growing in Cluſters.

14. RICINOIDES *paluſtre, fructu hiſpido, foliis ſubrotundis, nervoſis & aſperis. Houſt.* Marſh Phyſick-nut, with a prickly Fruit, and roundiſh ribbed Leaves, which are rough.

15. RICINOIDES *fruteſcens, lauri folio, calice ampliſſimo viridi. Houſt.* Shrubby Phyſick-nut, with a Bay Leaf, and a large green Flower-cup.

16. RICINOIDES, *ex qua paratur* TOURNESOL *Gallorum. Inſt. R. H. App.* Phyſick-nut, from which the *Tourneſol* of the *French* is made.

Theſe Plants are very common in the warm Parts of *America*. The firſt Sort is planted in Hedges, in moſt Parts of *Jamaica* and *Barbados*, and is propagated by Slips or Cuttings, which will take Root very freely, and do make a good Fence in a ſhort Time, being very quick of Growth. This riſes to be twenty Feet high, and produces a great Quantity of Nuts, which are given from three to ſeven for a Vomit; but if the thin Film be taken off, they may be eaten in Quantities without any ill Effect. There is an Oil drawn from theſe Seeds, which is uſed for burning in Lamps.

The ſecond Sort is cultivated in Gardens in *Jamaica* and *Barbados*, for the Beauty of its Flowers, which are of a fine ſcarlet Colour, and produced in large Bunches on divers Parts of the Plant. The Nuts of this Kind are larger than the other, but have much the ſame Quality. This is not a Native in any of the *Engliſh* Settlements in the *Weſt-Indies*, but was brought thither either from the *Spaniſh* or *French* Settlements, from whence it had the Names of *French* and *Spaniſh Phyſick-nut*.

The third Sort is very common in the *Savannas* in *Jamaica* and *Barbados*; the Seed of this Kind is the common Phyſick among the poorer Sort, for the dry Belly-ach.

The fourth Sort grows plentifully upon the Sea Coaſt in divers Parts of the *Weſt-Indies*, and is ſometimes brought into *England* as a Curioſity, where, in ſome very good Gardens it is preſerved with the former Sorts.

Theſe may be all propagated by ſowing their Seeds upon a Hot-bed in the *Spring*, and when the Plants are come up, they ſhould be each tranſplanted into a ſeparate Pot, filled with light, freſh Earth, and plunged into a Hot-bed of Tanners-bark, obſerving to ſhade them until they have taken Root, after which they ſhould have Air and Water in Proportion to the Warmth of the Seaſon, and the Hot-bed in which they are placed.

When their Roots have filled theſe Pots they ſhould be ſhaken out, and put into larger Pots, filled with the ſame freſh Earth, and plunged again into the Hot-bed; and ſo, from Time to Time, as the Plants advance, they ſhould be ſhifted into larger Pots; and when they are too high to be contained under a Frame, they ſhould be removed into the Bark-ſtove, where they may have Room to advance in Height, obſerving to water them duly, as they may require it; which, if conſtantly performed, and the Plants kept in a warm Bed, they will grow three or four Feet high the firſt *Summer*, and divide into ſeveral Branches in *Winter*.

Theſe Plants muſt be placed in a Bark-ſtove, (with other Plants which are the Produce of the ſame Countries) during which Seaſon they ſhould be often refreſh'd with Water, and the Stove ſhould be kept up to *Anana*'s Heat (as marked on Mr. *Fowler's* Thermometers); in this they will continue flouriſhing all the *Winter*, and early the next *Spring* will produce Flowers, which will be ſucceeded by Fruit.

Theſe Plants, if thus managed, will continue ſeveral Years, and annually produce a great Number of Flowers and Fruit, ſo that they are worthy of a Place in every curious collection of exotick Plants.

The fifth, ſixth, ſeventh, eighth, ninth, tenth and eleventh Sorts were diſcovered by Father *Plumier* in *America*: The fifth and ſixth Sorts have been found growing plentifully in the Iſland of *Jamaica*: The ninth, tenth, eleventh, twelfth, thirteenth and fourteenth Sorts were found in Plenty about *La Vera Cruz*, by the late Dr. *William Houſtoun*, from whence he ſent their Seeds to *England*: The fifteenth Sort was alſo diſcovered by the ſame Gentleman at *Jamaica*. All theſe Sorts are very tender Plants, being Natives of very warm Countries, and require to be tenderly treated, otherwiſe they will not grow in this Country. The ſixth, eleventh, twelfth, thirteenth and fourteenth Sorts are annual, ſo their Seeds muſt be ſown on a Hot-bed early in the *Spring*; and when the Plants are come up, they ſhould be tranſplanted each into a ſeparate ſmall Pot, filled with light rich Earth, and then plunged into a moderate Hot-bed of Tanners-bark, obſerving to ſhade them until they have taken Root; and then they ſhould have freſh Air admitted to them by raiſing of the Glaſſes every Day in warm Weather, and they muſt be frequently watered. In about a Month's Time, the Plants will have filled theſe Pots with their Roots, when they ſhould be ſhaken out, and put into larger Pots filled with rich Earth, and plunged again into the Hot-bed, provided there is Room for the Plants to grow in Height, without being preſſed by the Glaſſes; in which Caſe it will be proper to put them into the Bark-bed in the Stove; for they are too tender to thrive in the open Air in this Country, in the warmeſt Seaſon of the Year. In *July* theſe Plants will flower, and their Seeds will ripen in *Auguſt* and *September*, ſoon after which Time the Plants will decay.

The other Sorts which live over the Year, muſt be raiſed in the ſame Manner as the annual Kinds; but in *Winter* they muſt be plunged into the Bark-bed, in the warmeſt Stove, and treated after the ſame Manner as directed above.

The ſixteenth Sort is an annual Plant, and is found wild in the *South* of *France*, *Spain* and *Italy*, from which the *Tourneſol* is made, that is uſed for colouring of Wine and Jellies. This is made of the Juice which is lodged between the outer Cover and the Seeds; and if rubbed on Cloth, at firſt appeareth of a lively green Colour, but ſoon changeth to a bluiſh purple Colour: If theſe Cloths are put into Water, and afterward wrung, they will colour the Water of a Claret Colour. The Rags, thus dry'd, are brought to *England*, and ſold in the Druggiſts Shops, by the Name of *Turnſole*.

This Sort may be propagated by Seeds, which ſhould be ſown in the *Autumn*, ſoon after they are ripe, on a warm Border of freſh, light Earth; and if any of the Plants come up before *Winter* (which ſometimes happens) they ſhould be ſheltered in hard Froſt, otherwiſe they will not live through the *Winter*. But the Seeds generally remain in the Ground until the *Spring*, when the Plants will appear; at which Time they ſhould be cleaned from Weeds, and where the Plants are too cloſe, they ſhould be thinned, ſo as to leave them about ſix Inches aſunder; and in very dry Weather, if they are now and then refreſhed with Water, it will promote their Growth. This is all the Culture they require, except the keeping them conſtantly clear from Weeds; for the Plants do not thrive well, if they are tranſplanted, ſo they ſhould be ſown where they are deſigned to remain. In *July* the Plants will flower, and their Seeds will ripen in *Auguſt*, when the Plants will ſoon after decay.

RICINUS, [ſo called becauſe the Seed reſembles (*Ricinus*) the Animal called by that Name, *i. e.* a *Tick*, which infeſts Dogs and Oxen. It is alſo called *Palma Chriſti*, becauſe its Leaves are ſaid to reſemble the Palm of the Hand] Palma Chriſti, *vulgo*.

The *Characters* are;

The Flowers are apetalous, (i. e. *have no Leaves*) *conſiſting of many Stamina, which ariſe in the Center of the Flower-cup; theſe are barren; for the Embryo's are produced at remote Diſtances, upon the ſame Plant, which afterwards become triangular Fruits, having three Cells, in each of which is contained one oblong Seed, which has a hard Shell.*

The *Species* are;

1. RICINUS *vulgaris. C. B. P.* The common Palma Chriſti, commonly known in the *Weſt-Indies* by the Name of Oil-nut, *or* Agnus Caſtus.

2. RICINUS *vulgaris minor. C. B. P. caule rutilante.* The leſſer Palma Chriſti, with reddiſh Stalks, commonly called in *Barbados*, Red Oil-ſeed.

3. RICINUS *vulgaris minor. C. B. P. caule vireſcente.* Leſſer Palma Chriſti, with green Stalks, *commonly called* White Oil Seeds in *Barbados*.

4. RICINUS *Americanus major, caule vireſcente. H. R. P.* The greater Palma Chriſti, with green Stalks.

5. RICINUS *Africanus maximus, caule geniculato rutilante. H. R. Par.* The greateſt African Palma Chriſti, with reddiſh jointed Stalks.

6. RICINUS *Indicus, fructu rugoſo non echinato. Indian* Oil-ſeed, with a rough Fruit not echinated.

7. RICINUS *Americanus, fructu racemoſo hiſpido. John. Dend. American* Oil-ſeed, with prickly Fruit, growing in a Cluſter.

8. RICINUS *Americanus, fructu racemoſo glabro majore. Millar. American* Oil-ſeed, with larger ſmooth Fruit growing in a Cluſter.

9. RICINUS *Americanus minor, fructu racemoſo glabro. Millar.* Smaller *American* Oil-ſeed, with ſmooth Fruit, growing in Cluſters.

10. RICINUS Z*eylanicus, foliis profundius laciniatis. Inſt. R. H.* Oil-ſeed of *Ceylon*, with Leaves deeply cut in.

11. RICINUS *humilis, foliis ſubrotundis ſerratis, & ſubtus argenteis, flore fructuque conglomeratis. Houſt.* Dwarf Oil-ſeed, with roundiſh ſawed Leaves, which are ſilvery underneath, and the Flowers and Fruit growing in Bunches.

The firſt five of theſe Plants are very common in divers Parts of *Africa* and *America*, and ſome of them are alſo found in the warm Parts of *Europe*; but in *England* they are preſerved with great Care in ſeveral curious Gardens.

The firſt Sort has been a long Time in this Country, but was formerly treated as an annual Plant; whereas, if it be preſerved in a good Green-houſe, it will abide two or three Years, and become a large Plant.

The ſecond and third Sorts do grow promiſcuouſly all over *America*, where their Seeds are gathered to draw an Oil from them, for the Uſe of Lamps; theſe Seeds are frequently ſent into *England*, intermixed with each other.

The fourth Sort is alſo very common in *America*, growing promiſcuouſly with the common Sort; the Seeds of both being gathered indifferently to draw an Oil from them.

The fifth Sort, though mentioned to be a Native of *Africa*, yet is alſo very common in divers Parts of *America*, from whence I have ſeveral times received the Seeds. This produces very large Leaves and Seeds, and will grow to a large Size, if planted in a rich Soil. I have meaſured one of the Leaves of this Plant, (which was growing near *Chelſea*) which was upward of two Feet Diameter, and the Stem was as large as a middle-ſiz'd Broom-ſtaff, tho' but of one *Summer*'s Growth.

Theſe Plants may be propagated by ſowing their Seeds upon a Hot-bed; and when they are come up, they ſhould be each planted into a ſeparate Pot filled with light, freſh Earth, and plunged into a freſh Hot-bed, obſerving to water and ſhade them until they have taken Root; after which they muſt have a great Share of free Air, when the Seaſon is mild, otherwiſe they will draw up tall, and be very weak: And as theſe Plants grow very faſt, ſo their Roots will in a ſhort Time fill the Pots, therefore they ſhould be ſhifted into larger Pots filled with the like freſh Earth; and toward the latter End of *May*, when the Seaſon is warm, they may be hardened to endure the open Air by Degrees; and then, if they are planted out into a very rich Border, and in dry Weather duly watered, they will grow to a very large Size, particularly the firſt Sort, which I have ſeen upwards of ten Feet high in one Seaſon; and theſe Plants have produced a great Quantity of Flowers and Seeds: But if you intend to preſerve them through the *Winter*, they muſt never be placed in the full Ground, becauſe after their Roots have been widely extended, there will be no tranſplanting them with Safety; therefore the beſt Way is to ſhift them into larger Pots, from Time to Time, as their Roots ſhall require, placing them in the open Air during the *Summer* Seaſon, in ſome warm Situation, where they may remain until *October*, when they muſt be removed into the Houſe with other exotick Plants, obſerving duly to water them in *Winter*, and let them have free Air in mild Weather, for they only require to be protected from Froſt and cold Winds, ſo that they will endure the *Winter* in a common Green-houſe, without any Addition of artificial Warmth.

The firſt four Sorts will perfect their Seeds the firſt Seaſon in this Climate, provided they are ſown early in the *Spring*, but the fifth Sort will rarely produce any till the ſecond Year; ſo that there is a Neceſſity of preſerving this through the *Winter*, otherwiſe it cannot be maintained in *England*.

Theſe Plants do deſerve a Place in every curious Garden for the ſingular Beauty of their Leaves (notwithſtanding their Flowers are not very valuable) eſpecially thoſe Sorts which may be propagated every Year from Seeds, becauſe thoſe Perſons who have no Green-houſe to place them into in *Winter*, may cultivate them as other annual Plants; amongſt which theſe, being placed either in Pots or Borders, do afford an agreeable Variety; But it muſt be obſerved, as theſe are large growing Plants, never to place them too near other Plants of leſs Growth, becauſe theſe will overbear and deſtroy them; and thoſe which are planted in Pots ſhould be allowed Room for their Roots to expand, and muſt be frequently watered(otherwiſe they will not grow very large.

The Seeds of the ſixth Sort were brought from the *Eaſt-Indies*, which came up and flouriſhed in the Phyſick-garden at *Chelſea*. This Sort grows about the ſame Height as the common Kind, but the Leaves are not ſo deeply divided. The Coverings of the Seeds are not prickly, as in moſt of the other Sorts (ſomewhat reſembling the outer Cover of the Cheſnut); but are rough, and full of Protuberances.

The Seeds of the ſeventh and eighth Sorts were ſent from *Jamaica* by Mr. *Robert Millar*, who gathered them on the North Side of that Iſland. Theſe Plants grow in their native Country, to be eighteen or twenty Feet high, and continue two or three Years. They are nearly alike in their outward Appearance, but differ in the Covering of their Seeds, the ſeventh having prickly Covers, and the eighth being ſmooth.

The ninth Sort is a low Plant, ſeldom riſing above three Feet high, and differs from the common ſmall Sort, in having ſmooth Covers to the Seeds: This is leſs common, and hath not been remarked by any Botanical Writer.

The tenth Sort is a Native of *Ceylon*, from whence the Seeds were brought to *Holland*, and hath been cultivated in many curious Gardens. The Leaves of this Kind are very deeply jagged, in which it chiefly differs from the common Sort.

The eleventh Sort was diſcovered by the late Dr. *William Houſtoun* at *Campechy*, from whence he ſent the Seeds to *England*. This is a very low Plant, ſeldom riſing above eight or nine Inches high, and periſhes ſoon after the Seeds are perfected.

Theſe Sorts are propagated by Seeds, which muſt be ſown on a Hot-bed early in the *Spring*; and when the Plants are come up, they ſhould be treated in the ſame manner as above directed; with which Management theſe will thrive very well, except the laſt Sort, which is a tender Plant, ſo will not perfect Seeds in the open Air in this Country: Therefore this Sort ſhould remain in the Hot-bed, and in warm Weather the Glaſſes ſhould be raiſed to admit freſh Air to the Plants; and they muſt be frequently watered, otherwiſe their Seeds will not be well nouriſhed.

The ſeventh and eighth Sorts will not perfect their Seeds in this Climate the firſt Year, unleſs they are placed in the Stove, and forwarded early in the *Spring*; ſo that it will be proper to preſerve a Plant or two of each Kind through the *Winter*, in order to obtain good Seeds. But as they are tender Plants, ſo they muſt be kept in a moderate Temperature of Warmth, otherwiſe they will not live; therefore the beſt Way is to plunge the Pots into the Bark-bed in the Stove, which will keep them growing all the *Winter*, and cauſe them to make large handſome Plants by the following *Summer*.

RIPENING of FRUIT.

The Method of producing Early Fruits.

A Wall ſhould be erected ten Feet high, and in Length according to the Number of Trees intended for three Years Forcing.

This being done, a Border may be marked out about four Feet wide on the South Side of it, and ſome Scantlings of Wood, about four Inches thick, muſt be faſtened to the Ground in a ſtrait Line on the Outſide of the Border, to reſt the Glaſs Lights upon; which Lights are to ſlope backwards to the Wall, to ſhelter the Fruit as there ſhall be Occaſion.

Bars about four Inches wide, cut out of whole Deal, muſt be placed between theſe Glaſſes, ſo that the Lights may reſt on them.

If you would not have the Glaſs-lights ſlope ſo much as they will from this Fall from the Upright, then you may have a Line of Whole Deals fixed on the Top of the Wall to project their whole Breadth over the Trees, and made ſo, that the Top of the Glaſs-ſights may fall in an Inch or two under them: There muſt alſo be a Door ſhaped to the Profile of the Frame at each End, that it may be open'd at either of the Ends, according as the Wind blows.

The Frame before-mentioned ſhould be made ſo, that when the firſt Part has been forced, the Frame may be moved the next Year forward, and the ſucceeding Year forward again; ſo that the Trees will be forced but every third Year; and having two Years to recover themſelves, will continue ſtrong for many Years.

Theſe Trees ſhould be well grown before they are forced, otherwiſe they will ſoon be deſtroyed; and the Fruit produced on grown Trees, will be much fairer and better taſted, than on freſh-planted Trees.

The Fruit that may be planted in theſe Frames are,

The *Avant*, the *Albemarle*, the *Anne*, the *Early Newington* and *Brown Nutmeg Peaches*.

Mr. *Fairchild*'s *Early*, the *Elruge* and *Newington Nectarines*; the *Maſculine Apricock*; the *May Duke* and *May Cherry*.

As for *Grapes*, the *White* and *Black Sweet-water*.

Gooſeberries; the *Dutch White*, the *Dutch Early Green*, and the *Walnut Gooſeberries*.

Currants; the *Large Dutch White*, *the Large Dutch Red Currants*.

It has been found by Experience, that the Trees will be injured, if the Heat be apply'd before *November*: And that the Time for applying the Heat for bringing either *Duke* or *May Cherries*, is about the Middle or latter End of that Month, and applying Heat at the ſame Time would do for *Apricocks*; ſo that the *Maſculine Apricock* will in *February* be as large as *Duke Cherries*, and will be ripe by the Beginning of *April*.

Cherries thus forced will not hold ſo well as *Apricocks*, though the former will laſt, perhaps, for ſeven Years in good Plight; but *Apricocks* will thrive and proſper thus many Years.

It is very likely that Mr. *Fairchild*'s *Early Nectarines* would ripen much about the ſame Time as the *Maſculine Apricok*, if they were both forced at the ſame Time; and the *Brugnon Nectarine* would follow that. As to the forward Sorts of *Plums*, they have been try'd, and do ripen about the latter End of *April*.

Gooſeberries would produce green Fruit fit for Tarts in *January* and *February*, and probably would ripen about the End of *March*, or the Beginning of *April* at the fartheſt.

Currants, which tend to ſhoot forward, might, by the ſame Heat that brings *Cherries* in *February*, be forced to produce ripe Fruit in *April*, if not ſooner.

As for the Diſtance of theſe Trees one from another, it need not be ſo great as is directed for thoſe planted in the open Air, becauſe they will never ſhoot ſo vigorouſly, therefore eight or nine Feet will be ſufficient.

The higher Parts of the Wall being furniſhed with *Apricocks*, *Cherries*, *Nectarines*, *Peaches* and *Plums*, the lower ſmall Space between them may be filled up with *Currants*, *Gooſeberries* and *Roſes*.

As to the Pruning of theſe Trees:

The Time of doing it in theſe Frames muſt not be the ſame as in other Trees; becauſe in the common Caſe of *Stone-fruit* againſt Walls, the *Spring* does not begin till the End of *January*; but in the forcing Frames the *Spring* begins in *November*: Therefore they ſhould be pruned three Weeks before the Heat is apply'd; for then the Air will be ſo artificially tempered, as to ſet the Trees a growing, and the Froſts cannot come at them, if the Glaſſes be ſet up as ſoon as they are pruned.

As to the Nailing of theſe Trees:

Every Branch that ſhoots muſt be laid as cloſe to the Wall as can be; for the Fruit which touches the Wall will be ripe a Month ſooner than thoſe that lie but two Inches from it.

Sometimes it happens that the Tops of ſuch Trees have Bloſſoms a Month or ſix Weeks before the Bottom; and ſometimes one Branch has been full of Bloſſoms, when there have been half a Score or more Branches of the ſame Tree, which have not ſtirr'd till the Fruit of the firſt Bloſſoms has been almoſt ripe, notwithſtanding which the Tree has done very well: And it is no uncommon Thing for ſuch Trees to have Fruit ripening upon them for near three Months continually.

As for *Gooſeberries*; ſuch Plants as are planted in theſe Frames, ſhould be ſuch as have ſpread; and when as many Shoots have been nail'd to the Wall as may conveniently be done, others may be left at a Diſtance from it, to ſucceed them in ripening.

If they are taken up in the Summer, and properly manag'd, they will bear Fruit the firſt Year, as well as if they had not been tranſplanted.

The *Currants* may be order'd after the ſame Manner, and alſo the *Roſes:* And the beſt kind of *Roſe* for this Purpoſe, is the *Monthly Roſe*, which ought always to be topp'd about the End of *July*, or the Beginning of *Auguſt*, to make them put out a good Number of Flower-buds.

As to the laying the Dung to the Wall;

The Dung, before it be laid to the Back of the Wall, ſhould be thrown up in an Heap, and lie for ſome Days, that it may yield an equal Heat every where, and be conſtant.

When it has been thus prepar'd, it ſhould be laid about four Feet thick at the Baſe, and ſo ſloping, till it has but two Feet wide at the Top.

It ſhould be laid at firſt within four Inches of the Top of the Wall, for it will ſink to about three Feet in ſix Weeks time; and then ſome freſh Dung muſt be laid, becauſe the firſt Heat will not do much more than ſwell the Buds of the Trees, or begin to bring them to a green Colour, or at the moſt will but barely ſhew the Colour of the Bloſſom Buds.

But, according as the Froſts ſhall have happen'd to have had more or leſs Influence over the Buds, this will happen ſooner or later.

If theſe Trees be covered with the Glaſſes, it will contribute very much to forward their Bloſſoming; for tho' their Bloſſoms will not be deſtroy'd by the Froſts, yet the more the Froſts come at them, they will both be the drier and more hard to open.

If the Weather be tolerably mild, the Trees ought not to be hinder'd from the Benefit of the Showers till the Buds begin to ſtir; but afterwards the Glaſſes ſhould be kept conſtantly over them till the Influence of the Sun is ſomething conſiderable.

But the Doors which are at each End of the Frame, ſhould in the mean time be ſet open, when the Wind does not blow too ſharp, and the Sun ſhines any thing warm: And if this does not happen in the Space of a Fortnight, then the Doors at both Ends may be open'd, and Mats of Baſe or Canvaſs ſhould be hung up over the Door-ways to correct the Winds, and give the Air Leave to circulate in the Frames.

As for *Cherries*; about three Changes of Dung will be ſufficient to bring them to a due Ripeneſs in *February*, ſuppoſing each Parcel remains a Month at the Back of the Wall.

But as for *Apricocks*, *Grapes*, *Nectarines*, *Peaches* and *Plums*, if *April* proves cold, the forcing Heat muſt be continu'd till *May* is ſettled; but ſome of the Glaſſes ſhould be open'd in the Morning in *March* and *April*, when the Wind is ſtill, and the Sun warm; and they ſhould be permitted to receive the Showers that fall, while the Fruit is growing; but while they are in Bloſſom no Rain ſhould come near them, becauſe if there ſhould be any Moiſture lodg'd in the Boſom of the Flowers, and the Sun ſhould ſhine hot thro' the Glaſſes, it would be apt to deſtroy them.

The Dung that comes from theſe Frames having loſt its Heat, may be laid in Heaps to rot for the meliorating of ſtubborn Grounds.

Another Thing which ought to obſerv'd in planting Fruit in theſe Frames, is to plant thoſe Fruits which come forward together, and thoſe which come late by themſelves, becauſe it will be prejudicial to the forward Fruit, to give them any more Heat when they have done bearing, when at the ſame time the later Fruits ſet amongſt them may require more Heat, and to be continu'd longer, ſome of them, perhaps, requiring an artificial Heat till *May*.

There may alſo a Row or two of *Scarlet Strawberries* be planted near to the Back of this Frame; and theſe you may expect will be ripe by the End of *February*, or Beginning of *March*.

As for the *Vines*, they may probably be brought to bloſſom in *April*, and have ripe *Grapes* in *June*.

There may alſo be here and there planted a *Monthly Roſe-tree* and *Hyacinths*, *Jonquils*, *Narciſſus's*, *Polyanthus's*; and alſo early *Tulips* might be planted in the Borders.

A ROOT is that Part of a Plant by which it naturally draws in its Nouriſhment. The *Roots* of Plants being of various Forms, and each diſtinguiſh'd by a different Name, it will not be improper, in this Place, to inſert the Principal of thoſe which are diſtinguiſh'd. And firſt,

A fibroſe *Root* is that which conſiſts wholly of ſmall Fibres; as moſt Sorts of *Graſs*, *Pinks*, &c.

A tuberoſe *Root* is that which conſiſts of an uniform fleſhly Subſtance, and is of a roundiſh Figure; as *Turnips*, *Potatoes*, &c.

A bulbous *Root* is that which conſiſts either of ſeveral Coats involving one another; as *Onions*, *Tulips*, &c. or of ſeveral Scales lying over one another; as *Lillies Crown Imperials*, &c. The firſt of theſe is called a *tunicated Root*; the laſt a *ſquamoſe Root*.

A teſticulated *Root* is a double tuberoſe *Root*, for it conſiſts of two Knobs, reſembling a Pair of Teſticles; as in the *Orchis*.

A handed *Root* is a tuberoſe *Root*, divided, as it were, into ſeveral Fingers; as in the *handed Satyrions*.

A grumous *Root* is that which is compos'd of ſeveral Knobs, as the *Anemone*, &c.

A granulous *Root* is a kind of grumous *Root* with ſmall Knobs, reſembling ſo many Grains of Corn; as in the *White Saxifrage*.

A tap *Root* is a tuberoſe *Root* extended in Length; as in *Parſnips*, *Carrots*, &c.

RONDELETIA.

The *Characters* are;

It hath a ſalver-ſhaped Flower, conſiſting of one Leaf, which is tubulous, and reſts on the Empalement; which Empalement afterwards becomes roundiſh coronated Fruit, divided into two Cells, containing many ſmall Seeds.

We know but one *Species* of this Plant; which is,

RONDELETIA *arboreſcens, tini facie. Plum. Nov. Gen.* Tree-like Rondeletia, with the Face of *Laurus Tinus*.

This Plant was diſcovered by Father *Plumier*, in *America*, who gave it this Name in Honour to *Gulielmus Rondeletius*, a famous Phyſician of *Montpelier*.

The Seeds of this Plant were ſent to *England* by Mr *Robert Millar*, Surgeon, who collected them on the North-ſide of the Iſland of *Jamaica*, where the Trees grow plentifully, as alſo in ſeveral Parts of the *Spaniſh Weſt-Indies*.

This Plant is very tender, ſo cannot be preſerved in *England*, unleſs it is kept in a warm Stove. It is propagated by Seeds, which ſhould be ſown on a Hot-bed early in the *Spring*; and when the Plants are come up, they muſt be tranſplanted into ſeparate ſmall Pots, and plunged into a moderate Hot-bed of Tanners-bark, where they muſt be treated in the ſame manner as hath been directed for the *Pereskia*; and in Winter muſt be placed in the Tan-bed in the Stove, where theſe Plants will thrive, and in two or three Years will flower; when they will make an agreeable Variety amongſt other tender exotick Plants.

ROSA; The Roſe-tree.

The *Characters* are;

The Flower is compoſed of ſeveral Leaves, which are placed circularly, and do expand in a beautiful Order; whoſe leafy Flower-cup afterwards becomes a roundiſh or oblong fleſhy Fruit, incloſing ſeveral angular hairy Seeds: To which may be added, It is a weak, pithy Shrub, for the moſt part beſet with Prickles, and hath pinnated Leaves.

The *Species* are;

1. ROSA *ſylveſtris inodora, ſeu canina. Park. Theat.* The Wild Briar, Dog Roſe, *or* Hep-Tree.

2. ROSA *ſylveſtris, fructu majore hiſpido. Raii. Syn.* Wild Briar *or* Dog Roſe, with large prickly Heps.

3. ROSA *ſylveſtris pomifera major noſtras. Raii Syn.* The greater *Engliſh* Apple-bearing Roſe.

4. ROSA *pumilla ſpinoſiſſima, foliis pimpinellæ glabris, flore albo. J. B.* The Dwarf Wild Burnet-leav'd Roſe.

5. ROSA *pumilla ſpinoſiſſima, foliis pimpinellæ glabris, ex luteo & viridi eleganter variegatis.* The Dwarf Wild Burnet-leav'd Roſe, with variegated Leaves.

6. ROSA *pimpinella minor Scotica, floribus ex albo & carneo eleganter variegatis. Pluk. Alm.* The ſtrip'd Scotch Roſe.

7. ROSA *ſylveſtris, foliis odoratis. C. B. P.* The ſweet Briar *or* Eglantine.

8. ROSA *ſylveſtris odora ſive Eglanteria, flore duplici. Park. Parad.* Sweet Briar, with a double Flower.

9. ROSA *rubra multiplex. C. B. P.* The double Red Roſe.

10. ROSA *Damaſcena. Park. Parad.* The Damaſk Roſe.

11. ROSA *Provincialis, ſive Hollandica, Damaſcena. Park. Parad.* The Damaſk Provence Roſe.

12. ROSA *Provincialis major, flore pleno ruberrimo. Boerh. Ind. Alt.* The Red Provence Roſe.

13. ROSA *centifolia Batavica. Cluſ. H.* The Dutch-hundred-leav'd Roſe.

14. ROSA *Provincialis ſpinoſiſſima, pedunculo muſcoſo.* The Moſs Provence Roſe.

15. ROSA *Provincialis rubra. Park. Parad.* The Common Provence Roſe.

16. ROSA *holoſericea ſimplex. Park. Parad.* The ſingle Velvet Roſe.

17. ROSA *holoſericea multiplex. Park. Parad.* The double Velvet Roſe.

18. ROSA *odore Cinamomi, flore pleno. C. B. P.* The double Cinnamon Roſe.

19. ROSA *odore Cinamomi, ſimplex. C. B. P.* The ſingle Cinnamon Roſe.

20. ROSA *lutea ſimplex. C. B. P.* The ſingle yellow Roſe.

21. ROSA *lutea multiplex. C. B. P.* The double yellow Roſe.

22. ROSA *ſylveſtris Auſtriaca, flore Phœnicio. Park. Theat.* The Auſtrian Roſe.

23. ROSA *ſylveſtris Auſtriaca, flore totum luteum.* The yellow Auſtrian Roſe.

24. ROSA *uno ramo luteos, cæteris puniceos flores gerens ſimplices. Boerh. Ind. Alt.* The Auſtrian Roſe, with yellow Flowers upon one Branch, and purple Flowers on the other.

25. ROSA *alba vulgaris major. C. B. P.* The Common white Roſe.

26. ROSA *alba minor. C. B. P.* The leſſer white Roſe.

27. ROSA *candida ſemiplena. J. B.* The ſemi-double white Roſe.

28. ROSA *incarnata. Park. Parad.* The Bluſh Roſe.

29. ROSA *Præneſtina variegata plena. Hort. Eyſt.* The York and Lancaſter Roſe.

30. ROSA *rubro & albo variegata, Roſa mundi, vulgo dicta. Raii Hiſt.* The Roſe of the World, or *Roſa mundi*.

31. ROSA *Francofurtenſis. Park. Parad.* The Frankfort Roſe.

32. ROSA *ſemper-virens. Park. Parad.* The Ever-green Roſe.

33. ROSA *omnium calendarum. H. R. Par.* The Monthly Roſe.

34. ROSA *omnium calendarum, flore variegato.* The ſtrip'd Monthly Roſe.

35. ROSA *ſine ſpinis, flore minore. C. B. P.* The Roſe without Thorns.

36. ROSA *ſine ſpinis, flore majore ruberrimo.* The Royal Virgin Roſe.

37. ROSA *ſylveſtris Virginienſis. Raii Hiſt.* The Wild Virginian Roſe.

38. ROSA *moſchata, ſimplici flore. C. B. P.* The ſingle Muſk Roſe.

39. ROSA *moſchata, flore pleno. C. B. P.* The double Muſk Roſe.

40. ROSA *moſchata ſemper-virens. C. B. P.* The Ever-green Muſk Roſe.

41. ROSA *Belgica, ſive vitrea, flore rubro. Rea. Flor.* The red Belgick Roſe.

42. ROSA *Belgica, ſive vitrea, flore rubicante. Rea. Flor.* The bluſh Belgick Roſe.

43. ROSA *marmorea. Rea. Flor.* The marbled Roſe.

44. ROSA *Provincialis, flore ſimplici.* The ſingle Provence Roſe.

45. ROSA *Damaſcena, flore ſimplici.* The ſingle Damaſk Roſe.

46. ROSA *pimpinella minor Scotica, flore livide rubente.* The Dwarf Scotch Roſe, with a bluiſh Red Flower.

47. ROSA *ſylveſtris Virginiana, flore majore pallido.* The wild *Virginian* Roſe, with a larger pale Flower.

48. ROSA *Americana moſchata, flore minore.* The *American* Muſk-roſe, with a ſmaller Flower.

49. ROSA *Americana odoratiſſima ſerotina, flore pallido pleno.* The moſt ſweet-ſcented *American* late-flowering Roſe, with a double Flower.

The firſt Sort of *Roſe* grows wild in the Hedges in moſt Parts of *England:* The Fruit of this Tree is made into a Conſerve for Medicinal Uſe; but this is ſeldom cultivated in Gardens.

The ſecond, third, and fourth Sorts do alſo grow wild in divers Parts of *England*, and are rarely preſerved in Gardens, unleſs for Variety ſake.

The fifth Sort is a Variety of the fourth, and is preſerved by ſome for the Beauty of its ſtrip'd Leaves.

The ſixth Sort is found wild in *Scotland*, and has been by many ſuppos'd to be the ſame as the fourth Sort, but only differing therefrom in having variegated Flowers; which is a great Miſtake, for I have obſerv'd, where the two Sorts were cultivated on the ſame Soil for many Years, and yet retain'd a conſiderable Difference in the Size of the Plants, the *Scotch* Sort being not half ſo large as the other, yet the Flowers were much larger, the Leaves were leſs, and the Branches much weaker than thoſe of the fourth Sort.

The laſt Sort here mention'd, was raiſed from the Seeds of the *Scotch Roſe*; and altho' the Flowers were plain-coloured, yet the whole Appearance of the Plant continues the ſame as the original Kind, which is a plain Proof of its being different from the fourth Sort.

The *Sweet-Briar*, altho' wild in ſome Parts of *England*, yet is preſerv'd in moſt curious Gardens, for the extreme Sweetneſs of its Leaves, which perfumes the circumambiant Air in the Spring of the Year, eſpecially after a Shower of Rain. The Flowers of this Sort being ſingle, are not valued, but the Branches of the Shrubs are cut to intermix with Flowers to place in Baſons to adorn Halls, Parlours, &c. in the Spring of the Year, the Scent of this Plant being agreeable to moſt Perſons.

The Double-flower'd *Sweet-Briar* is preſerved on the Account of its Beautiful Flowers, as well as for the Sweetneſs of its green Leaves.

All the other Sorts of *Roſes* are originally of foreign Growth, but are hardy enough to endure the Cold of our Climate in the open Air, and produce the moſt beautiful and fragrant Flowers of any kind of Shrubs yet known: This, together with their long Continuance in Flower, has juſtly render'd them the moſt valuable of all the Sorts of flowering Shrubs, beſides the great Variety of different Sorts of *Roſes*, do make a Collection of Flowers, either for Baſons or in the Garden, without any other additional Mixture; and their Scent being the moſt inoffenſive Sweet, is generally eſteem'd by moſt Perſons.

But in order to continue theſe Beauties longer than they are naturally diſpoſed to laſt, it is proper to plant ſome of the monthly *Roſes* near a warm Wall, which will occaſion their Budding at leaſt three Weeks or a Month before thoſe in the open Air; and if you give them the Help of a Glaſs before them, it will bring their Flowers much forwarder, eſpecially where Dung is placed to the Backſide of the Wall (as is practiſed in raiſing early Fruits:) By this Method I have ſeen fair *Roſes* of this Kind blown in *February*, and they may be brought much ſooner, where People are curious this way.

You ſhould alſo cut off the Tops of ſuch Shoots which have been produc'd the ſame Spring, early in *May*, from ſome of theſe Sorts of *Roſes* which are planted in the open Air, and upon a ſtrong Soil: This will cauſe them to make new Shoots, which will flower late in *Autumn*; as will alſo the late removing the Plants in *Spring*, provided they do not ſuffer by Drought, as I have ſeveral times experienced; but particularly in the Year 1718, when I had occaſion to remove a large Parcel of theſe Plants in *May*, juſt as they were beginning to flower: In doing of which I cut off all the Flower-buds, and, after having opened a Trench in the Place where they were to be planted, I poured a large Quantity of Water, ſo as to render the Ground like a Pap; then I took up the Plants, and placed them therein as ſoon as poſſible, that their Roots might not dry; and after planting them, I water'd the Ground well again, and cover'd the Surface over with Mulſh, to prevent its drying; after this I repeated watering the Plants all over two or three times a Week in the Evening, until they had taken Root; In about three Weeks time the Plants ſhot out again, and produc'd a great Quantity of Flowers in *Auguſt* and *September*, which were as fair as thoſe produc'd in *June*. This is the only Sort of *Roſe* for this Purpoſe, there being no other Sort which will flower both early and late, except this.

The next Sort of *Roſe* which flowers in the open Air, is the *Cinnamon*, which is immediately follow'd by the *Damask Roſe*; then the *Bluſh*, and *York*, and *Lancaſter* come; after which the *Provence*, *Dutch*, *Hundred leav'd White*, and moſt other Sorts of *Roſes* do follow; and the lateſt Sorts are the two *Muſk Roſes*, which, if planted in a ſhady Situation, do ſeldom flower until *September*; and if the *Autumn* proves mild, will continue often till the middle of *October*.

The Plants of theſe two Sorts ſhould be placed againſt a Wall, Pale, or other Building, that their Branches may be ſupported otherwiſe they are ſo ſlender and weak, as to trail upon the Ground; theſe Plants ſhould not be pruned until *Spring*, becauſe their Branches are ſomewhat tender, ſo that when they are cut in *Winter*, they often die after the Knife. Theſe produce their Flowers at the Extremity of the ſame Year's Shoots, in large Bunches, ſo that their Branches muſt not be ſhorten'd in the *Summer*, leſt hereby the Flowers ſhould be cut off. Theſe Shrubs will grow to be eight or nine Feet high, and muſt not be check'd in their Growth, if you intend they ſhould flower well, ſo that they ſhould be placed where they may be allowed Room.

The loweſt Shrub of all the Sorts here mentioned, is the *Scotch Roſe*, which rarely grows above two Feet high, ſo that this muſt be placed among other Shrubs of the ſame Growth. The *Red Roſe* and the *Roſa mundi* do commonly grow from three to four Feet high, but ſeldom exceed that; but the *Damask*, *Provence*, and *Frankfort Roſes* grow to the Height of ſeven or eight Feet; ſo that in planting of them great Care ſhould be taken to place their ſeveral Kinds, according to their various Growths, amongſt other Shrubs, that they may appear beautiful to the Eye.

The *Frankfort Roſe* is of little Value, except for a Stock to bud the more tender Sorts of *Roſes* upon, for the Flowers do ſeldom open fair, and have no Scent; but it being a vigorous Shooter, renders it proper for Stocks to bud the *Yellow* and *Auſtrian Roſes*, which will render them ſtronger than upon their own Stocks; but the *Yellow Roſes* do ſeldom blow fair within eight or ten Miles of *London*, tho' in the Northern Parts of *Great Britain* they do flower extremely well. This Sort muſt have a Northern Expoſure; for if it is planted too warm, it will not flower.

All the Sorts of *Roſes* may be propagated either from Suckers, Layers, or by budding them upon Stocks of other Sorts of *Roſes*; which latter Method is only practiſed for ſome peculiar Sorts, which do not grow very vigorous upon their own Stocks, and ſend forth Suckers very ſparingly; or where a Perſon is willing to have more Sorts than one upon the ſame Plant; but then it muſt be obſerv'd to bud ſuch Sorts upon the ſame Stock as are nearly equal in their manner of Growth; for if there be a Bud of a vigorous growing Sort, and ſome others of weak Growth, the ſtrong one will draw all the Nouriſhment from the weaker, and entirely ſtarve them.

The beſt Sort for Stocks is the *Frankfort Roſe*, which is a vigorous Grower, and produces ſtrong clean Shoots, which will take the Buds much better than any other Sort of *Roſe*; but you muſt be very careful to keep the Stock after Budding intirely clear from Suckers or Shoots at the Bottom; for if they are permitted to remain on, they will, in a ſhort time, ſtarve the Buds. The beſt Seaſon for budding of *Roſes* is in *June*; the Manner of doing it, being the ſame as for Fruit-trees, need not be repeated here.

If you would propagate them from Suckers, they ſhould be taken off annually in *October*, and tranſplanted out either into a Nurſery in Rows, (as hath been directed for ſeveral other Sorts of flowering Shrubs) or into the Places where they are to remain; for if they are permitted to ſtand upon the Roots of the old Plants more than one Year, they grow woody, and do not form ſo good Roots as if planted out the firſt Year, and ſo there is more Danger of their not ſucceeding.

But the beſt Method to obtain good rooted Plants, is to lay down the young Branches in *Autumn*, which will take good Root by the *Autumn* following, (eſpecially if they are watered in very dry Weather) when they may be taken from the old Plants, and tranſplanted where they are to remain. Theſe Plants may be tranſplanted any Time from *October* to *April*; but when they are deſign'd to flower ſtrong the firſt Year after planting, they ſhould be planted early; tho', as I ſaid before, if they are planted late in the *Spring*, it will cauſe them to flower in *Autumn*, provided they do not ſuffer by Drought.

Moſt of theſe Sorts do delight in a rich, moiſt Soil, and an open Situation, in which they will produce a greater Quantity of Flowers, and thoſe much fairer, than when they are upon a dry Soil, or in a ſhady Situation. The Pruning which they require, is only to have their dead Wood cut out, and the Suckers cleared off, which ſhould be done every *Autumn*; and if there are any very luxuriant Branches, which draw the Nouriſhment from the other Parts of the Plant, they ſhould be taken out, or ſhorten'd, to cauſe it to produce more Branches, if there be Occaſion for them to ſupply a Vacancy; but you muſt avoid crouding them with Branches, which is as injurious to theſe Plants as to Fruit-trees; for if the Branches have not an equal Benefit of the Sun and Air, they will not produce their Flowers ſo ſtrong, nor in ſo great Plenty, as when they are more open and better expos'd to the Sun, ſo that the Air may circulate the more freely between them.

The laſt three Sorts of *Roſes* grow wild in the Woods of *North America*, from whence their Seeds have been ſent to *England*, and great Numbers of the Plants have been raiſed. They are extremely hardy, ſo may be planted in any Situation, but they love a moiſt light Soil. They may be propagated by Layers or Suckers, in the ſame manner as the common Sorts of *Roſes*; and being intermixed with them, they will add to the Variety. There is ſome Variation in the Colour of the Flowers of theſe Sorts, which hath ariſen from the Seeds which were brought over, as there frequently happens with all the other Sorts of *Roſes*; for of late Years, ſince ſome curious Perſons have ſowed the Seeds of *Roſes*, there have been many new Varieties obtained, ſome of which are very double, and of beautiful Colours; which Succeſs ſhould encourage others to practiſe this Method, ſince there is not a more beautiful *Genus* of Plants in Nature, than that of the *Roſe*; and the greater Variety there can be obtained, the more will they be valued, on account of their ſeveral Succeſſions, whereby they are, one or other of the *Species*, in Flower above five Months.

ROSA SINENSIS; *vide* Ketmia Sinenſis.

ROSE THE GUILDER; *vide* Opulus.

ROSE-TREE; *vide* Roſa.

ROSEMARY; *vide* Roſmarinus.

ROSMARINUS: [ſo call'd of *Ros*, *Dew*, and *Marinus*, *Lat.* belonging to the *Sea*, q. d. *Sea-Dew*, as ſome ſay, becauſe formerly growing in great Plenty near the Shore of the *Mediterranean* Sea, the Vapours thence ariſing, us'd to fall on it in the Manner of Dew] Roſemary.

The *Characters* are;

It is a verticillate Plant, with a labiated Flower, conſiſting of one Leaf, whoſe Upper-lip or Creſt is cut into two Parts, and turns up backwards, with crooked Stamina (or Chives); but the Under-lip (or Beard) is divided into three Parts, the middle Segment being hollow like a Spoon; out of the two or three-teethed Flower-cup riſes the Pointal, attended, as it were, by four Embryo's, which afterwards turn to ſo many Seeds, that are roundiſh, and are incloſed in the Flower-cup.

The *Species* are;

1. Rosmarinus *hortenſis, latiore folio. Mor. Hiſt.* Broad-leav'd Garden Roſemary.
2. Rosmarinus *hortenſis, anguſtiore folio. C. B. P.* Narrow-leav'd Garden Roſemary.
3. Rosmarinus *ſtriatus, ſive aureus. Park. Theat.* The Gold-ſtrip'd Roſemary.
4. Rosmarinus *hortenſis, anguſtiore folio, argenteus. H. R. Par.* The Narrow-leav'd Silver-ſtrip'd Roſemary.
5. Rosmarinus *Almerienſis, flore majore ſpicato purpuraſcente. Tourn.* Roſemary of Almeria, with a large ſpiked purpliſh Flower.
6. Rosmarinus *ſpontaneus, folio eleganter variegato. Boerh. Ind.* Broad-leav'd Roſemary, with an elegant ſtrip'd Leaf.

Theſe Plants grow plentifully in the Southern Parts of *France*, in *Spain* and *Italy*, where, upon dry rocky Soils near the Sea, they thrive prodigiouſly; but notwithſtanding they are produc'd in warm Countries, yet they are hardy enough to bear the Cold of our ordinary *Winters* very well in the open Air, provided they are planted upon a poor, dry, gravelly Soil, on which they will endure the Cold much better than upon a richer Soil, where the Plants will grow more vigorouſly in *Summer*, and ſo be more ſubject to Injury from Froſt, and they will not have ſo ſtrong an Aromatick Scent as thoſe upon a dry barren Soil.

Theſe ſorts with ſtrip'd Leaves are ſomewhat tender, and ſhould either be planted near a warm Wall, or in Pots fill'd with light freſh Earth, and ſhelter'd in *Winter* under a Frame, otherwiſe they will be ſubject to die in froſty Weather.

All theſe ſorts may be propagated by planting Slips or Cuttings of them in the *Spring* of the Year, upon a Bed of a light freſh Earth; and when they are rooted, they may be tranſplanted into the Places where they are deſign'd to grow, but it will be proper to do this about the Beginning of *Auguſt*, that they may take new Root before the froſty Weather comes on; for if they are planted too late in *Autumn*, they ſeldom live through the *Winter*, eſpecially if the Weather proves very cold; ſo that if you do not tranſplant them early, it will be the better Method to let them remain unremoved until *March* following, when the Froſt is over, obſerving never to tranſplant them at a Seaſon when the dry Eaſt Winds blow, but rather defer the doing of it until the Seaſon is more favourable; for if they are planted when there are cold drying Winds, they are apt to dry up their Leaves, and kill them: But if there happens to be ſome warm Showers ſoon after they are removed, it will cauſe them to take Root immediately; ſo that they will require no farther Care, but to keep them clear from Weeds.

Altho' theſe Plants are tender when planted in a Garden, yet when they are by Accident rooted in a Wall, (as I have ſeveral times ſeen them) they will endure the greateſt Cold of our Winters, though expos'd much to the cold Winds, which is occaſion'd by the Plants being more ſtunted and ſtrong, and their Roots being drier.

The Flowers of the Narrow-leav'd Garden ſort are uſed in Medicine, as are alſo the Leaves and Seeds.

RUBEOLA, Petty-madder.

The *Characters* are;

It hath a funnel-ſhaped Flower, conſiſting of one Leaf, which is ſlightly cut into four Parts at the Brim; reſting on the Empalement, which is ſometimes double, and ſometimes ſingle. This Empalement afterward becomes a Fruit, compoſed of two naked Seeds.

The *Species* are;

1. Rubeola *latiori folio. Inſt. R. H.* Broad-leaved Petty-madder.
2. Rubeola *anguſtiore folio. Inſt. R. H.* Narrow-leaved Petty-madder.
3. Rubeola *vulgaris quadrifolia lævis, floribus purpuraſcentibus. Inſt. R. H.* Common ſmooth four-leaved Petty-madder, with purpliſh Flowers, commonly called Squinency-wort.
4. Rubeola *Luſitanica aſpera, floribus purpuraſcentibus. Inſt. R. H.* Rough Petty-madder of *Portugal*, with purpliſh Flowers.
5. Rubeola *Cretica ſaxatilis fruticoſa, gallii folio, flore purpureo violaceo. Tourn. Cor.* Shrubby rocky Petty-madder of *Candy*, with a ladies-bedſtraw Leaf, and a violet purple Flower.
6. Rubeola *Cretica ſexatilis fruteſcens, flore flaveſcente. Tourn. Cor.* Shrubby rock Petty-madder of *Candy*, with a yellowiſh Flower.
7. Rubeola *Cretica fœtidiſſima fruteſcens myrtifolia, flore magno ſuave-rubente. Tourn. Cor.* The moſt ſtinking ſhrubby Petty-madder of *Candy*, with a myrtle Leaf, and a large pale red Flower.
8. Rubeola *Orientalis fœtida fruticoſa ſerpyllifolia, flore parvo ſuave-rubente. Tourn. Cor.* Shrubby ſtinking Eaſtern Petty-madder, with a mother-of-thyme Leaf, and a ſmall pale red Flower.
9. Rubeola *Orientalis, foliis gallii, flore multiplici ex viridi flaveſcente. Tourn. Cor.* Eaſtern Petty-madder, with many greeniſh yellow Flowers.

The firſt, ſecond, fourth and ninth Sorts, are annual Plants, which decay ſoon after they have perfected their Seeds. Theſe are preſerved in the Gardens of thoſe Perſons who are curious in Botany, for the ſake of Variety. They are very hardy Plants, which require no other Care than to clear them from Weeds: for if they are permitted to ſcatter their Seeds, the Plants will come up and maintain their Place, if they are not overborne with larger Plants. The Seeds of theſe Plants may be ſown either in *Spring* or *Autumn*, in the Places where they are to remain, which may be in almoſt any Soil, but they love an open Situation.

The third Sort grows wild on chalky Hills in divers Parts of *England*, where the Branches trail on the Ground, and produce Tufts of purpliſh Flowers from the Joints where the Leaves are ſet on, which open in *June*, and the Seeds are ripe in *Auguſt*; but the Roots abide many Years. This Plant is eſteemed efficacious in the Cure of Quinſeys, either taken inwardly, or outwardly applied.

The fifth, ſixth, ſeventh and eighth Sorts, were diſcovered by Dr. *Tournefort* in the *Levant*. Theſe are abiding Plants, which become ſhrubby, and by their different Appearances, make an agreeable Variety in a Garden. They may be propagated by ſowing of their Seeds on a Bed of freſh undunged Soil, in the *Spring*; and when the Plants come up, they muſt be kept clear from Weeds, and in very dry Weather they ſhould be refreſhed with Water; and when the Plants are about three or four Inches high, they ſhould be tranſplanted, ſome of each Sort, into Pots, that they may be ſheltered under a Hot-bed Frame in Winter; and the others into dry warm Borders of poor Earth: for in ſuch Places where the Plants grow ſlowly, they will live thro' the *Winter*, better than when they are planted in a rich Soil.

RUBIA; [takes its Name from its red Colour, becauſe the Root of this Plant is uſed in dying a red Colour] Madder.

The *Characters* are;

The Flower conſiſts of one ſingle Leaf, which is cut into four or five Segments, and expanded at the Top; the Flower-cup afterwards becomes a Fruit compoſed of two juicy Berries, cloſely joined together, containing Seed, for the moſt part hollowed like a Navel; to which may be added, the Leaves being rough, and ſurrounding the Stalks in Whorles.

The *Species* are;

1. Rubia *tinctorum ſativa. C. B. P.* Cultivated Dyers Madder.
2. Rubia *ſylveſtris aſpera, quæ ſylveſtris Dioſcoridis. C. B. P.* Wild Madder.
3. Rubia *ſylveſtris Monſpeſulana major. J. B.* Great Wild Madder of *Montpelier*.

The firſt of theſe Sorts was formerly cultivated in divers Parts of *England*, for the Dyers Uſe; but of late Years it has been wholly neglected, ſo that at preſent I believe there is ſcarce any of it cultivated, except in ſmall Quantities for Medicinal Uſe: How this Plant came to be ſo much neglected in *England* I cannot imagine, ſince it will thrive as well here as in any Country in *Europe*; and the Conſumption of it in *England* is pretty large; for I have been inform'd, that we pay upwards of thirty thouſand Pounds annually for this Commodity, which might be eaſily ſav'd to the Nation, were it cultivated here. At preſent the greateſt Quantity of it is cultivated in *Flanders* and *Holland*, from whence we are annually furniſh'd with it, in three different Manners, and diſtinguiſhed by the Names of *Madder in the Branch*, *Madder in the Bundle*, and *Madder unbundled*: The firſt ſort is brought to us in the Root, as it comes out of the Ground, without any other Preparation than that of being dried. The ſecond Sort is that of *Bunch Madder*, or ſuch as is made into Bundles, which is *Madder in Branch*, firſt freed from the Bark and the Pith, then ground by a Mill into groſs Powder, as we buy it. The third Sort is the *Madder unbundled*, that is the *Branched Madder* ground into Powder; but the *Bunched Madder*, or that in Bundles, is the beſt, which, for its Excellency, when it is freſh, is made into Bales, or put up into Casks; 'tis of a pale Red, but as it grows older, increaſes its Colour to a fine Red; that of *Zealand* is eſteem'd the beſt for the Dyers Uſe.

In the Year 1727. I obſerv'd a great Quantity of this Plant cultivated in *Holland*, between *Helvoetſluice* and the *Brill*; and it being the firſt Time I had ever ſeen any conſiderable Parcel of it, I was tempted to make ſome Enquiries about its Culture, and take ſome Minutes of it down upon the Spot, which I ſhall here inſert, for the Uſe of ſuch as may have Curioſity to attempt the Culture of it.

In *Autumn* they plough the Land, where they intend to plant *Madder* in the *Spring*, and lay it in high Ridges, that the Froſt may mellow it; in *March* they plough it again, and at this Seaſon they work it very deep, laying it up in Ridges eighteen Inches aſunder, and about a Foot deep; then about the Beginning of *April*, when the *Madder* will begin to ſhoot out of the Ground, they open the Earth about their old Roots, and take of all the Side-ſhoots which extend themſelves horizontally, juſt under the Surface of the Ground, preſerving as much Root to them as poſſible: theſe they tranſplant immediately upon the Tops of the new Ridges, at about a Foot apart, obſerving always to do this when there are ſome Showers, becauſe then the Plants will take Root in a few Days, and will require no Water.

When the Plants are growing, they carefully keep the Ground houghed, to prevent the Weeds from coming up between them, for if they are ſmothered by Weeds, eſpecially when young, it will either deſtroy or weaken them ſo much, that they ſeldom do well after. In theſe Ridges they let the Plants remain two Seaſons, during which Time they keep the Ground very clean, and at *Michaelmas*, when the Tops of the Plants are decayed, they take up the Roots and dry them for Sale. This is what I could learn of their Method of cultivating this Plant; to which I will ſubjoin a few Obſervations of my own, which I have ſince made upon the Culture of *Madder* in *England*. And, firſt, I find there is no Neceſſity for laying the Ground up in Ridges in *England*, as is practiſed by the *Dutch*, (eſpecially in dry Land) becauſe the Places where I ſaw it were very wet Land, which is often floated in *Winter*: ſo that if the Plants were not elevated upon Ridges, their Roots would rot in *Winter*. Secondly, They ſhould be planted at a greater Diſtance in *England*, the Rows ſhould be at leaſt three Feet Diſtance, and the Plants eighteen Inches aſunder in the Rows; for as they extend themſelves pretty far under Ground, ſo where they are planted too near, their Roots will not have Room to grow. And, thirdly, I find, that if all the horizontal Roots are deſtroyed from time to time, as they are produced, it will cauſe the large downright Roots to be much bigger, in which the Goodneſs of this Commodity chiefly conſiſts: For if the upper Roots are ſuffered to remain, they will draw off the principal Nouriſhment from the downright Roots, as I have experienced; for I planted a few Roots upon the ſame Soil and Situation, which were of equal Strength, and rooted equally well; half of theſe I houghed round, and cut off the horizontal Roots, and the other half I permitted the horizontal Roots to remain on, and when I took them all up, thoſe which I had houghed about and kept clear from horizontal Roots, were almoſt as large again as the other, and the Roots were double the Weight, which plainly proves it neceſſary to cut off thoſe ſuperficial Roots.

The Manner of drying and preparing theſe Roots for Uſe, I am not acquainted with, having never had an Opportunity of ſeeing that Part, ſo can give no Inſtructions concerning it; but whoever ſhall have Curioſity enough to cultivate this uſeful Plant, might eaſily inform themſelves, by going over to *Holland* at the Seaſon of taking up the Roots.

The two Sorts of *Wild Madder* are of no Uſe; though their Roots ſeem to be of the ſame Quality with the manured Sort; and as they are never cultivated in Gardens, it is needleſs to ſay any Thing more of them in this Place.

Theſe Plants love a looſe Soil, neither too dry nor over wet, but will do better in a dry than on a wet Soil, becauſe in ſuch Places the Roots are apt to rot in *Winter*.

RUBUS; [This Plant is ſo called of the red Colour of the Fruit before it comes to Maturity] The Bramble *or* Raſpberry-buſh.

The *Characters* are;

It hath a Flower conſiſting of five Leaves, which are placed circularly, and do expand in form of a Roſe; *the Flower-cup is divided into five Parts, containing many Stamina, or Chives, in the Boſom of the Flower, in the Centre of which riſes the Pointal, which afterwards becomes the Fruit, conſiſting of many Protuberances, and full of Juice.*

The *Species* are;

1. Rubus *major, fructu nigro. J. B.* The common Bramble *or* Blackberry-buſh.
2. Rubus *minor, fructu cæruleo. J. B.* The Dewberry-buſh, *or* Leſſer Bramble.
3. Rubus *vulgaris major, fructu albo. Raii Syn.* The common Greater Bramble-buſh, with white Fruit.
4. Rubus *vulgaris major, folio eleganter variegato.* The Greater Bramble-buſh, with a beautiful ſtrip'd Leaf.
5. Rubus *Idæus, ſpinoſus, fructu rubro. J. B.* The Raſpberry-buſh, Framboiſe, *or* Hind-berry.
6. Rubus *Idæus, ſpinoſus, fructu albo. J. B.* The Raſpberry-buſh, with white Fruit.
7. Rubus *Idæus, ſpinoſus, fructu rubro ſerotino.* The Raſpberry-buſh, with late red Fruit.
8. Rubus *Idæus, non ſpinoſus. J. B.* The Raſpberry-buſh, without Thorns.
9. Rubus *Idæus, fructu nigro, Virginianus. Baniſter.* The Virginian Raſpberry-buſh, with black Fruit.
10. Rubus *odoratus. Cornut.* Virginian flowering Raſpberry, *vulgo*.
11. Rubus *Americanus, magis erectus, ſpinis rarioribus, ſtipite cæruleo. Pluk. Alm.* The Upright Penſylvania Bramble, *or* Raſpberry-buſh.
12. Rubus *Alpinus humilis. J. B.* Dwarf Bramble of the Alps.
13. Rubus *vulgaris, ſpinis carens. H. R. Par.* Common Bramble, without Spines.
14. Rubus *ſpinoſus, foliis & flore eleganter laciniatis. Inſt. R. H.* Prickly Bramble, with Leaves and Flowers elegantly jagged.
15. Rubus *flore albo pleno. H. R. Par.* The Bramble with double white Flowers.
16. Rubus *non ſpinoſus, fructu nigro majore, Polonicus. Barr. Icon.* Poland Bramble without Thorns, and a larger black Fruit.

The firſt and ſecond Sorts are very common in Hedges, and upon dry Banks in moſt Parts of *England*, and are rarely cultivated in Gardens. The third Sort was found by Mr. *Jacob Bobart*, in a Hedge not far from *Oxford*, and hath ſince been cultivated in ſeveral Gardens as a Curioſity. This does not only differ from the common *Bramble* in the Colour of the Fruit, but alſo in the Colour of the Bark and the Leaves, which, in this Sort, are of a lively green; whereas thoſe of the common Sort are of a dark brown Colour. The fourth Sort is a Variety of the common *Bramble*, differing therefrom only in having ſtriped Leaves, for which it is preſerved by ſome Perſons, who are curious in collecting variegated Plants.

The *Raſpberry-buſh* is alſo very common in divers Woods in the Northern Counties of *England*, but is cultivated in all curious Gardens for the ſake of its Fruit. Of this there are three Kinds, which are cultivated commonly in Gardens near *London*; which are the common red, late red, and the white Sorts; but the Sort without Thorns is leſs common at preſent than the other.

The ninth, tenth, eleventh and twelfth Sorts are preſerved as Curioſities in ſeveral Gardens near *London*; but as their Fruits are of no Value, ſo they are ſcarcely worth cultivating, except in Botanick Gardens for Variety.

All theſe Plants are eaſily propagated by Suckers, which they ſend from the Roots in great Plenty. The beſt Time to take them off and tranſplant them, is in *October*, that they may take good Root before *Winter*; which will cauſe them to be ſtrong, and produce Fruit the ſucceeding *Summer*.

In preparing theſe Plants, their Fibres ſhould be ſhortened; but the Buds which are placed at a ſmall Diſtance from the Stem of the Plant, muſt not be cut off, becauſe thoſe produce the new Shoots the following *Summer*. Theſe Plants ſhould be planted about two Feet aſunder in the Rows, and four or five Feet Diſtance Row from Row; for if they are planted too cloſe, their Fruit is never ſo fair, nor will ripen ſo kindly as when they have Room for the Air to paſs between the Rows. The Soil in which they thrive beſt, is a freſh, ſandy Loam, neither too moiſt nor over dry, the Extreme of either being injurious to theſe Plants.

The Time for dreſſing of them is in *October*, when all the old Wood, which produced Fruit the preceding *Summer*, ſhould be cut out down to the Surface of the Ground, and the young Shoots muſt be ſhortened to about two Feet in Length; then the Spaces between the Rows ſhould be well dug, to encourage their Roots; and if you bury a very little rotten Dung therein, it will make them ſhoot vigorouſly the *Summer* following, and their Fruit will be much fairer. During the *Summer* Seaſon they ſhould be kept clear from Weeds, which, with the before-mentioned Culture, is all the Management they will require: But it is proper to make new Plantations once in three or four Years, becauſe thoſe are better than ſuch Plants as are ſuffered to remain longer.

All the other Sorts are propagated from Suckers in the ſame Manner as the Garden *Raſpberries*, and are equally hardy, ſo that they may be placed in the open Air in any Part of the Garden, provided it be not over moiſt, which is apt to rot the Roots of ſome Sorts in *Winter*, but eſpecially of the *Canada* Sort, which is apt to periſh, if planted in a very wet Soil.

The thirteenth Sort is in all Reſpects like the common Bramble, excepting in this Particular, that there are no Thorns on the Branches or Leaves of this Sort.

The fourteenth Sort differs from the common Bramble, in having the Leaves and Flowers curiouſly jagged.

The fifteenth Sort produces large Spikes of Flowers, which are very large and double, ſo that they make a fine Appearance, being almoſt as large and double as Roſes. This merits a Place in every good Garden, becauſe it may be planted in any abject Part of the Garden, under Trees in Wilderneſs Quarters, where it will thrive and flower as well as when planted in a more open Situation.

The ſixteenth Sort is not very common in *England*, but is a Native of *Poland*. This produces much larger Fruit than the common Bramble; ſo is preſerved in the Gardens of ſome curious Perſons for the ſake of Variety.

All the Sorts of Bramble are eaſily propagated by laying down of their Shoots, which in one Year will be ſufficiently rooted to tranſplant; ſo may then be cut off from the old Plants, and planted where they are deſign'd to remain; which ſhould be in Wilderneſs Quarters, or other abject Parts of the Garden, where they may have Room to ſpread, without incommoding other Plants.

RUELLIA.

The *Characters* are ;

It hath a Funnel-ſhaped Flower, conſiſting of one Leaf, which is cut into ſeveral Parts at the Brim, from whoſe Empalement ariſes the Pointal, which is fixed like a Nail in the Bottom of the Flower, and afterward becomes a membranaceous Pod, which opens into ſeveral Parts, and is filled with ſmall Seeds.

The *Species* are ;

1. RUELLIA *Americana humilis, aſphodeli radice. Plum. Nov. Gen.* Dwarf American Ruellia, with an aſphodel Root.
2. RUELLIA *Carolinana, foliis oblongis anguſtis, flore purpureo. Houſt.* Carolina Ruellia, with narrow oblong Leaves, and a purple Flower.
3. RUELLIA *Americana humilis, parvo flore cœruleo, capſulis teretibus. Houſt.* Dwarf American Ruellia, with a ſmall blue Flower, and a taper Pod.

The firſt Sort was diſcovered by Father *Plumier* in *America*, who gave this Name to the *Genus*, in Honour of Dr. *Ruellius*, who was a very learned Perſon in Natural Hiſtory, and lived about two hundred Years paſt.

The ſecond Sort grows plentifully in *South Carolina*, from whence it was brought into the *Engliſh* Gardens. This Sort grows much taller than the other two.

The third Sort was diſcover'd by the late Dr. *William Houſtoun* in *Jamaica*, who ſent the Seeds into *England*. The Flowers of this Kind are much ſmaller than thoſe of the other Sorts, and are of ſhort Duration, ſeldom continuing above one Day.

Theſe Plants are propagated by Seeds, which muſt be ſown early in the *Spring* in Pots filled with light, rich Earth, and plunged into a moderate Hot-bed ; and when the Plants come up, they muſt be tranſplanted each into a ſeparate ſmall Pot, filled with rich Earth, and plunged into a Hot-bed of Tanners-bark, where they muſt be ſhaded from the Sun, until they have taken new Root ; after which Time they muſt have freſh Air admitted to them every Day in warm Weather, and be conſtantly watered three or four times a Week during the *Summer* Seaſon. If the Plants thrive well, thoſe of the firſt and third Sort will produce Flowers the *July* following, and will perfect their Seeds in *Auguſt* ; but the Roots will continue, provided they are plunged into the Bark-bed in the Stove, and kept in a moderate Temperature of Heat.

The ſecond Sort, which riſes much higher than either of the other, will require to be ſhifted into larger Pots, by the Beginning of *June* ; and then they ſhould be removed into the Stove, or a Glaſs-caſe, where they may have a larger Share of Air ; otherwiſe they will draw up very weak, which will prevent their flowering. This Sort dies to the Root every *Winter* ; but if the Pots are placed in a warm Stove, their Roots will live and put out again the following *Spring*, ſo may be continued ſeveral Years. This Sort will ripen Seeds very well, provided the Plants are ſhelter'd when they are in flower.

The firſt Sort is by much the moſt beautiful Plant, the Flowers being four times as large as thoſe of either of the other Sorts, and are of a fine blue Colour ; ſo that it makes a fine Appearance when it flowers ; and as the Plants are ſmall, ſo they may be kept in a little Compaſs, and are as well worth preſerving, as moſt tender exotick Plants. When this Plant is ſhifted, (which ſhould be the Beginning of *April*, before the new Leaves are put out) great Care ſhould be taken, that the Roots are not broken or bruiſed ; for as they conſiſt of many thick Tubers, ſo if theſe are injured the Plant is frequently deſtroy'd.

RUSCUS : [ſo called of *Ruſticus*, *q. d.* a *ruſtick Plant*, becauſe the Countrymen in old Time uſed to lay it upon their Fleſh to defend it from Mice. It is alſo called *Laurus*, becauſe it is fit for making Laurel Garlands. It is alſo call'd *Alexandrina*, from its growing in *Alexandria*] Knee-holly, Butchers-broom.

The *Characters* are ;

The Flower-cup conſiſts of one Leaf, which is cut into ſeveral Diviſions, out of which is produced a globular Bell-ſhap'd Flower, conſiſting alſo of one Leaf, in the Centre of which riſes the Pointal, which afterwards becomes a ſoft, roundiſh Fruit, in which is incloſed one or two hard Seeds.

The *Species* are ;

1. RUSCUS *myrtifolius aculeatus. Tourn.* The common Knee-holly, *or* Butchers-broom.
2. RUSCUS *anguſtifolius, fructu folio innaſcente. Tourn.* Narrow-leafed Butchers-broom, *or* Alexandrian Laurel, with the Fruit growing on the Leaves.
3. RUSCUS *latifolius, fructu folio innaſcente. Tourn.* Broad-leafed Butchers-broom, *or* Alexandrian Laurel, with the Fruit growing on the Leaves.
4. RUSCUS *anguſtifolius, fructu ſummis ramulis innaſcente. Tourn.* Narrow-leafed Butchers-broom, *or* Alexandrian Laurel, with the Fruit growing upon the Tops of the Branches.
5. RUSCUS *latifolius crenatus, fructu è crenis foliorum prodeuntibus.* Broad-leafed Alexandrian Laurel, with the Fruit growing upon the Edges of the Leaves.

The firſt Sort is very common in the Woods in divers Parts of *England*, and is rarely cultivated in Gardens. The Roots of this Kind are ſometimes uſed in Medicine, and the green Shoots are cut and bound into Bundles, and ſold to the Butchers, who uſe it as Beſoms to ſweep their Blocks ; from whence it had the Name of *Butchers-broom*.

The ſecond, third and fourth Sorts are hardy Plants, and though not Natives of *England*, yet may be preſerved in Gardens, if planted in a ſhady Situation, as in Wilderneſs-Quarters, *&c.* where they ſerve to intermix with other Wood-plants, to make Variety ; and the third Sort is ſometimes uſed in Medicine. Theſe Plants may be propagated by parting their Roots in the *Spring* of the Year, before they begin to make new Shoots, obſerving, if the Seaſon be dry, to water them until they have taken Root ; after which they will require no farther Care but to keep them clear from Weeds, obſerving not to tranſplant or diſturb their Roots oftener than once in three or four Years, for when they are often removed, they ſeldom thrive well, and do rarely produce Fruit.

The fifth Sort is tender, and muſt therefore be placed in Pots filled with freſh Earth, and in *Winter* put into the Green-houſe ; but it ſhould be placed where it may have free Air in mild Weather, and be conſtantly watered : In which Management this Plant will ſend forth Stems ſix or eight Feet high, furniſh'd with Leaves from Bottom to Top, which in *June* will be cloſely ſet with Flowers upon their Edges, which do make a very beautiful and odd Appearance, and renders it worthy of a Place in every good Collection of Plants. This is alſo propagated by parting the Roots, as the former, which ſhould not be done very often, becauſe if the Roots are not permitted to remain ſome Time to get Strength, they will produce but weak Shoots, and very few Flowers ; and in the Strength of their Shoots, and Number of Flowers, the greateſt Beauty of theſe Plants conſiſts.

It is generally ſuppoſed, that it was one of theſe Plants which the ancient Victors were crowned with ; and ſince from the pliableneſs of their Branches, whereby they are very proper to wreathe into any Figure, as alſo from the Reſemblance thoſe Coronets, which we ſee ſurrounding the Heads of ſome ancient Buſts, have to the Leaves of theſe Plants ; ſo that it is a probable Conjecture at leaſt.

RUTA ; [This Plant is called *Ruta*, of ῥύω, to *preſerve*, becauſe it is a Plant very good to preſerve Health] Rue.

The *Characters* are ;

The Flower for the moſt part conſiſts of four hollow Leaves, which are placed orbicularly, and do expand in form of a Roſe ; out of whoſe Flower-cup riſes the Pointal, which afterwards becomes a roundiſh Fruit, which is generally four-corner'd, and compoſed of four Cells fixed to an Axis, and full of ſmall angular Seeds.

The *Species* are ;

1. RUTA *major hortenſis latifolia. Mor. Hiſt.* The common broad-leafed Garden Rue.
2. RUTA *hortenſis minor tenuifolia. Mor. Hiſt.* The leſſer Garden Rue, with narrow Leaves.
3. RUTA *hortenſis minor tenuifolia, foliis variegatis argenteis. Boerh. Ind.* The leſſer Garden Rue, with narrow Leaves, variegated with White.
4. RUTA *Chalepenſis latifolia, florum petalis villis ſcatentibus. H. L.* The broad-leafed Aleppo Rue, whoſe Flower-leaves are beſet with Down.
5. RUTA *Chalepenſis tenuifolia, florum petalis villis ſcatentibus. Mor. Hiſt.* Narrow-leafed Aleppo Rue, whoſe Flower-leaves are beſet with Down.
6. RUTA *ſylveſtris major. C. B. P.* Greater Wild Rue.

There are ſome other Varieties of theſe Plants, which are preſerved in curious Botanick Gardens; but thoſe here mentioned are all the Sorts which I have ſeen cultivated in the *Engliſh* Gardens.

The firſt Sort here mentioned is that which the College of Phyſicians have directed to be uſed in Medicine, and is the moſt commonly cultivated in *England*.

The ſecond Sort is propagated but in few Gardens in *England*; though the third, which is a Variety of the ſecond, and only differing from it in having its Leaves variegated with White, is very common in *England*, being greatly cultivated by thoſe Gardeners who ſupply the *London* Markets with Plants in the *Spring* Seaſon, at which Time this Plant makes a beautiful Appearance; but as the Seaſon advances, and the Plants increaſe in Vigour, ſo the Variegation of the Leaves goes off, and they appear almoſt green; but their Colour returns again in *Winter*.

The two Sorts of *Aleppo Rue* are only preſerved in ſome curious Gardens, being rarely uſed in Medicine; though of late Years the broad-leafed Sort was become ſo plenty, as to be brought to the Markets inſtead of the firſt Sort: But it being much ranker, and of a more offenſive Smell, it was neglected.

The greater *Wild Rue* is leſs common in *England* than either of the former. This I raiſed from Seeds, which were ſent me by my honoured Friend Mr. *Henry Hopkey*, from *Gibraltar*, where this Plant grows upon the Hills in great Plenty.

All theſe Plants may be propagated either by ſowing of their Seeds, or by planting Slips or Cuttings, both of which muſt be done in the *Spring*. The Manner of propagating them from Cuttings being the ſame with *Roſemary*, &c. I ſhall not repeat it here, but refer the Reader to that Article; and if they are propagated by Seeds, there needs no farther Care but to dig a Bed of freſh Earth in the *Spring*, making it level; then to ſow the Seeds thereon, treading them in, and raking the Ground ſmooth: After which you muſt obſerve to keep the Bed clear from Weeds, until the Plants are come up about two Inches high; when they ſhould be tranſplanted out into freſh Beds, where they may remain for Uſe. All theſe Plants muſt have a dry Soil, otherwiſe they are very ſubject to be deſtroyed in *Winter*. The two *Aleppo Rues* and the *Wild Rue* are ſomewhat tenderer than the common Sort; but theſe will endure our ordinary *Winters* very well in the open Air, eſpecially if they are planted on a dry Soil.

Theſe Plants were formerly uſed to plant for Edgings on the Sides of Borders; but they are by no Means proper for this Uſe, for they ſhoot ſo vigorouſly that there is no keeping them within the Bounds of an Edging; beſides, when they are kept cloſely ſheered, they appear very ragged and ſtumpy, and their Roots do ſpread ſo far as to exhauſt the Goodneſs of the Soil, ſo that the other Plants would be deprived of their Nouriſhment; which Reaſons have cauſed them to be wholly neglected for this Purpoſe; ſo that at preſent they are chiefly cultivated for medicinal Uſe, or to furniſh the Balconies for the Citizens in the *Spring*.

RUTA CANINA; *vide* Scrophularia.

RUTA MURARIA; Wall Rue, *or* White Maidenhair.

This Plant is found growing out of the Joints of old Walls in divers Parts of *England*, where it is gathered for medicinal Uſe; but as it cannot be cultivated in Gardens, ſo as to grow to Advantage, I ſhall not ſay any Thing more of it in this Place.

RUYSCHIANA.

The *Characters* are;

It hath a labiated Flower, conſiſting of one Leaf, whoſe Upper-lip (or Creſt) is divided into two Parts; but the Beard is cut into three Segments, the middle Segment being divided into two Parts, and is twiſted like a Screw: Out of the Empalement ariſes the Pointal, fixed like a Nail in the hinder Part of the Flower, attended by four Embryo's, which afterwards become ſo many Seeds incloſed in the Empalement.

We have but one *Species* of this Plant, which is,

RUYSCHIANA *flore cœruleo magno. Boerh. Ind. alt.* Ruyſchiana, with a large blue Flower.

This Name was given to this Plant by the learned Dr. *Boerhaave*, Profeſſor of Botany at *Leyden*, in Honour of Dr. *Ruyſch*, who was Profeſſor of Anatomy and Botany at *Amſterdam*. It was by ſome Writers in Botany ranged amongſt the Hyſſops; by others it was made a Ground-pine, and by ſome a Self-heal, to neither of which it exactly agreed: Which occaſioned Dr. *Boerhaave* to conſtitute a new *Genus* of it by this Name.

This is a perennial Plant, which dies to the Root in *Autumn*, and riſes again the following *Spring*: It commonly grows about two Feet high, and has long narrow Leaves, ſomewhat reſembling thoſe of Roſemary; on the Tops of the Stalk the Flowers are produced in a cloſe thick Spike, growing in Whorles round the Stalks, which are of a fine blue Colour, and make a very pretty Appearance during their Continuance in Beauty; which in a cool Seaſon is ſometimes ſix Weeks, beginning in *May*, and laſting till *July*.

It is propagated by Seed, which ſhould be ſown in the Middle of *March*, in a Bed of freſh, light Earth, in an open Expoſure; and in about five Weeks after, the Plants will appear; when they ſhould be carefully cleared from Weeds; and if the Seaſon ſhould prove dry, they muſt be refreſhed now and then with Water, which will greatly promote their Growth. When the Plants are about two Inches high, they ſhould be carefully tranſplanted into a Bed or Border of freſh, light, undunged Earth, obſerving to ſhade them from the Sun until they have taken Root, as alſo to refreſh them frequently with Water, until they are well eſtabliſhed in this Bed; after which Time they will require no farther Care, but to keep them conſtantly clear from Weeds till *Michaelmas*, when they are to be removed into the Places where they are deſigned to remain for good.

When the Plants are firſt tranſplanted from the Seed-bed into the Nurſery-bed, they ſhould be planted about ſix Inches aſunder every Way, which will be ſufficient Room for them the firſt Seaſon: And this will admit of the Hough to come between the Plants to deſtroy the Weeds, which is by much a better Method than the pulling out of the Weeds by hand, and is much ſooner performed. For as the Hough ſtirs the Ground between the Plants, it not only cuts down the Weeds, which were up and viſible, but alſo deſtroys all thoſe whoſe Seeds were ſprouted, and would have ſoon after appeared; ſo that one houghing, if well performed, and in dry Weather, will more effectually deſtroy the Weeds than two hand Weedings would do, were it performed ever ſo carefully. Beſides, the ſtirring of the Ground is of great Service to the Plants.

At *Michaelmas*, when the Plants are tranſplanted for good, they ſhould be carefully taken up with Balls of Earth to their Roots, and they muſt be planted in the Middle of the Borders, in freſh light Earth, intermixing them with other hardy Plants of the ſame Growth, where they will make a pretty Appearance when they are in flower, and will continue three or four Years; and in ſome poor ſtony Soils I have known the Roots live ſix or ſeven Years; but theſe did not produce ſo large Spikes of Flowers as thoſe which were younger and more vigorous Plants.

It will be proper to have ſome of theſe Plants in Pots, which, in caſe of a ſevere *Winter*, may be ſheltered under a Frame, for fear thoſe Plants which are expoſed ſhould be deſtroyed; and theſe Plants in Pots, if they are duly ſupply'd with Water in dry Weather, will flower very ſtrong; ſo may be placed amongſt other Plants to decorate Courts, &c. where they will have a good Effect.

But as theſe Plants do not continue many Years, ſo it will be proper to raiſe a Supply of young Plants to ſucceed them; for the old Plants will produce Seeds plentifully, which are ripe in *Auguſt*, when they ſhould be gathered in dry Weather, and kept in a warm dry Room, till the Time for ſowing of them.

S A

SABINA; The Savine-Tree.

The *Characters* are:

It hath compact, rigid, and prickly Ever-green Leaves; the Fruit is ſmall, ſpherical, and warted, and the whole Plant has a very rank, ſtrong Smell.

The *Species* are;

1. SABINA *folio tamariſci Dioſcoridis. C. B. P.* The Male *or* common Savin.
2. SABINA *folio cupreſſi. C. B. P.* The Berry-bearing *or* Upright Savin.
3. SABINA *folio variegato.* The ſtrip'd Savin.

Theſe Plants are commonly cultivated for Medicinal Uſe, and are rarely planted in Gardens for Pleaſure, becauſe their ill Scent renders them diſagreeable in frequented Places; but yet they may be admitted for planting in Clumps, or to form Amphitheatres of Ever-green Trees; where, if theſe are intermix'd amongſt other low-growing Plants, they will add to the Variety.

Theſe Plants may be propagated by laying down their young Branches in the *Spring*; which, if duly watered in dry Weather, will take Root in a Year's Time, and may then be tranſplanted out either into a Nurſery, or the Places where they are to remain: They may alſo be propagated by Cuttings, which ſhould be planted on a moiſt Soil about the Beginning of *April*, which, if duly water'd, will take Root, and the *Spring* following may be remov'd, as was directed for the *Layers*.

The Time for tranſplanting theſe Plants is the ſame with moſt other Ever-green Trees, (*viz.*) in *April*, obſerving to do it in cloudy Weather, laying a little Mulſh upon the Surface of the Ground about their Roots to prevent their drying: After they are rooted, they will require no farther Care but to keep them clear from Weeds, and to dig the Ground about their Roots every *Spring*, which will greatly promote their Growth.

SAFFRON; *vide* Crocus.

SAGE; *vide* Salvia.

SALICARIA; [takes its Name from *Salix*, a *Sallow* or *Willow*, becauſe it grows on the Banks of Ditches under Willows. The Ancients call'd it *Lyſimachia*] Willow-wort, *or* ſpiked Loſe-ſtrife.

The *Characters* are;

The Flowers conſiſt of ſeveral Leaves, which are placed circularly, and do expand in form of a Roſe; theſe Leaves are produced from the Inciſures of the Flower-cup; from the Centre of the Flower-cup riſes the Pointal, which afterwards becomes a Fruit or oval Huſk, conſiſting of two Cells, and generally full of ſmall Seeds, which adhere to the Placenta, and are commonly wrapped up in the Flower-cup.

The *Species* are;

1. SALICARIA *vulgaris purpurea, foliis oblongis. Tourn.* Purple-ſpiked Willow-herb, *or* Loſe-ſtrife, with long Leaves.
2. SALICARIA *purpurea, foliis ſubrotundis. Tourn.* Purple-ſpiked Willow-herb, *or* Loſe-ſtrife, with roundiſh Leaves.
3. SALICARIA *hyſſopi folio latiore. Inſt. R. H.* Broad hyſſop-leaved Willow-wort, or Hedge-hyſſop.
4. SALICARIA *hyſſopi folio anguſtiore. Inſt. R. H.* Narrow hyſſop-leaved Willow-wort, or Graſs-poly.
5. SALICARIA *Luſitanica, anguſtiore folio. Inſt. R. H.* *Portugal* Willow-wort, with a narrow Leaf.
6. SALICARIA *Hiſpanica, hyſſopi folio, floribus oblongis, ſaturatè cœruleis. Inſt. R. H.* *Spaniſh* Willow-wort, with a Hyſſop-leaf, and oblong deep blue Flowers.
7. SALICARIA *minima Luſitanica, nummulariæ folio. Inſt. R. H.* The leaſt *Portugal* Willow-wort, with a money-wort Leaf.
8. SALICARIA *Orientalis, ſalicis folio acutiſſimo & glabro. Tourn. Cor.* Eaſtern Willow-wort, with a ſharp-pointed ſmooth willow Leaf.
9. SALICARIA *Cretica, punicæ folio. Tourn. Cor.* Candy Willow-wort, with a pomegranate Leaf.

Theſe Plants are very common by the Sides of Ditches and other moiſt Places in divers Parts of *England*, and are rarely cultivated in Gardens; yet, for the Beauty of their long Spikes of purple Flowers, they deſerve a Place in a good Garden, as alſo for their long Continuance in Flower: However, if there happens to be a moiſt boggy Place in a Garden where few other Plants will thrive, theſe may be placed there to Advantage, and will afford a great deal of Pleaſure. They propagate themſelves very faſt by their creeping Roots, ſo that if they delight in the Soil, they will in a ſhort Time multiply exceedingly. Theſe produce their Flowers in *June* and *July*, and do often continue till *Auguſt* in Beauty.

The third and fourth Sorts are found wild in *England*, on moiſt Soils, where the Water ſtands in *Winter*; but they are pretty rare near *London*. Theſe are ſeldom preſerved in Gardens, but are here mentioned to introduce the next Sort, which is a very beautiful Plant, and deſerves a Place in every curious Garden, for its long Continuance in Flower. This Sort is a Native of *Portugal*, but is a tolerable hardy Plant, and will endure the Cold of our ordinary *Winters* in the open Air; but in very ſevere Froſts, it is ſometimes deſtroyed; ſo that ſome Plants of this Kind may be planted in Pots, which may be ſheltered under a common Frame in *Winter*, where they ſhould have as much free Air as poſſible in mild Weather; for they only require to be protected from very hard Froſts. In *Summer* they may be placed abroad with other flowering Plants; but in dry Weather they muſt be duly watered, otherwiſe they will not flower ſtrong, nor continue ſo long in Beauty. Theſe Flowers are produced from the Wings of the Leaves, beginning at the Bottom of the Stalks near the Root, and are continued all the Way up to the Top of the Stalks, which are about two Feet in Length, for this Sort ſeldom riſes any higher: the Flowers are pretty large, and of a bright purple Colour. This Plant begins to flower the Beginning of *June*, and continues till *Auguſt*.

As this Sort very rarely produces ripe Seeds in *England*, ſo it muſt be propagated by parting of the Roots, or by laying down of the Branches, which will take Root in a few Months (provided they are conſtantly watered in dry Weather); and may then be taken from the old Plants, and planted into Pots, that they may be ſheltered in *Winter*; and the *Spring* following, ſome of them may be ſhaken out of the Pots, and planted into a Border, where they may have the morning Sun; and in dry Weather, if they are watered conſtantly, they will flower very well, and make a fine Appearance.

The ſixth Sort is alſo a very beautiful Plant, and well deſerves a Place in every good Garden. This grows about the ſame Height with the former, ſo may be interſperſed with it in the Borders of the Flower-garden; as may alſo the ſeventh and ninth Sorts, for Variety, tho' they are not near ſo beautiful as either of the former Sorts. Theſe may be treated in the ſame manner as hath been directed for the fifth Sort: with which Management they will thrive very well.

The eighth Sort grows much taller than either of the other, ſo ſhould be placed amongſt larger Plants. This is very hardy, and may be propagated either by Seeds, or by parting of the Roots, which is the ſureſt way, becauſe the Seeds do not ripen every Year in this Climate. The beſt time to part the Roots, is in *Autumn*, that they may be well fixed in the Ground before the *Spring*; becauſe thoſe which are parted in the *Spring*, ſeldom flower very ſtrong, eſpecially if the Seaſon proves dry. This ſort may be intermixed with the firſt and ſecond, and will grow in almoſt any Situation, provided they are watered in dry Weather.

SALICORNIA, Jointed Glaſſwort, or Saltwort.

The *Characters* are;

It hath an apetalous Flower, wanting the Empalement; for the Stamina (or Chives) and the Embryo's grow on the extreme Part of the Leaves. Theſe Embryo's afterwards become Pods or Bladders, which for the moſt part contain one Seed.

The *Species* are;

1. SALICORNIA *geniculata ſempervirens. Tourn. Cor.* Jointed evergreen Glaſſwort.
2. SALICORNIA *geniculata annua. Tourn. Cor.* Annual Jointed Glaſſwort.

Theſe Plants grow on the Sea-coaſt in many Parts of *Europe*, and upon the Shores in ſeveral Places in *England*, which are waſhed every Tide with the Salt-water; but are rarely planted in Gardens, becauſe it is very difficult to make them grow in any other Situation, than in ſalt Marſhes, and on the Shores, where the Salt-water frequently flows. Of theſe Plants there ſeem to be two or three Varieties, which appear remarkably different, but are not ſuppoſed to be diſtinct Species.

The Inhabitants near the Sea-coaſt, where theſe Plants grow, cut them up toward the latter End of *Summer*, when they are fully grown; and after having dried them in the Sun, they burn them for their Aſhes, which are uſed in making of Glaſs and Soap. Theſe Herbs are by the Country People, called *Kelp*; and are promiſcuouſly gathered for Uſe.

From the Aſhes of theſe Plants is extracted the Salt, called *Sal Kali* or *Alkali*, which is much uſed by the Chymiſts.

The manner of gathering and burning of theſe Herbs is already mentioned under the Article of *Kali*; ſo I ſhall not repeat it in this Place.

In ſome Parts of *England*, theſe Herbs are gathered and Pickled for Samphire, tho' it is very different there from.

SALIX; takes it Name of *ſalio*, to *leap* or *dance*, becauſe of its quick Growth] The Sallow *or* Willow-Tree.

The *Characters* are;

It hath amentaceous Flowers, conſiſting of ſeveral Stamina, which are collected into a Spike, but are barren; the Embryo's are produced upon different Trees from the Male Flowers, and do afterwards become a Fruit or Husk, ſhaped like a Cone, opening in two Parts, and containing downy Seeds.

The *Species* are;

1. Salix *vulgaris alba arboreſcens. C. B. P.* The common White Willow.

2. Salix *folio laureo, ſeu lato glabro odorato. Phyt. Brit.* The Bay-leav'd Sweet Willow.

3. Salix *folio longo, utrinque virente odorato.* The Long-leav'd Sweet Willow.

4. Salix *folio longo, latoque ſplendente, fragilis. Raii Syn.* The Crack Willow.

5. Salix *folio Amygdalino, utrinque aurito, corticem abjiciens. Raii Syn.* The Almond-leav'd Willow that caſts its Bark.

6. Salix *folio auriculato ſplendente, flexilis. Cat. Cant.* The round-ear'd ſhining Willow.

7. Salix *folio longo ſubluteo, non auriculato, viminibus luteis. Raii Syn.* The long-leav'd yellowiſh Willow.

8. Salix *latifolia rotunda. C. B. P.* Round-leav'd Sallow.

9. Salix *latifolia rotunda variegata.* The ſtrip'd Sallow.

10. Salix *latifolia, folio ſplendente. Raii. Syn.* Broad ſhining-leav'd Sallow.

11. Salix *Orientalis, flagellis deorſum pulchre pendentibus. T. Cor.* The Weeping Willow.

There are a greater Number of *Species* to be found in *England* than are here mentioned, eſpecially of the *Sallows*, as I have been inform'd by a very judicious Basket-maker: There are at leaſt thirty Sorts, which they diſtinguiſh by Name, commonly in uſe in their Trade; and beſides theſe, there are a great Number of Mountain *Willows*, which grow upon dry Grounds; but as theſe are ſeldom cultivated, ſo it would be to little Purpoſe to enumerate them in this Place.

All the Sorts of *Willows* may be eaſily propagated by planting Cuttings or Sets in the *Spring*, which do readily take Root, and are of quick Growth. Thoſe Sorts which grow to be large Trees, and are cultivated for their Timber, are generally planted from Sets, which are about ſeven Feet long: Theſe are ſharpen'd at their larger End, and thruſt into the Ground by the Sides of Ditches and Banks where the Ground is moiſt; in which Places they make a conſiderable Progreſs, and are a great Improvement to ſuch Eſtates, becauſe their Tops will be fit to lop every third or fourth Year. The larger Wood, if ſound, is commonly ſold for making Wooden Heels, or Soles for Shoes, as alſo to the Turners for many Kinds of light Ware.

The *Sallows* are commonly planted in Cuttings, made from ſtrong Shoots for the former Year, and are about three Feet long: Theſe are commonly thruſt down two Feet deep into Ground, and are one Foot above it. The Soil ſhould always be dug or ploughed before they are planted, and the Cuttings placed about three Feet Row from Row, and eighteen Inches aſunder in the Rows, obſerving always to place the Rows the ſloping way of the Ground, (eſpecially if the Tides overflow the Place) becauſe if the Rows are placed the contrary Ways, all the Weeds and Filth will be detain'd by the Plants, which will choak them up. The beſt Seaſon for planting theſe Cuttings is in *February*, for if they are planted ſooner, they are apt to peel, if it proves hard Froſt, which greatly injures them. Theſe Plants are always cut every Year, and if the Soil be good, they will produce a great Crop; ſo that the yearly Produce of one Acre has been often ſold for fifteen Pounds; but ten Pounds is a common Price, which is much better than Corn Land; ſo that it is great Pity theſe Plants are not more cultivated, eſpecially upon moiſt boggy Soils, upon which few other Things will thrive.

SALT is a foſſil Body, fuſible by Fire, and congealable again, in the Cold, into brittle Glebes or Cryſtals; ſoluble withal in Water, ſo as to diſappear therein, never malleable, and having ſomething in it, which, to the Organ of Taſte, affords a Senſation of Acrimony and Sharpneſs.

Dr. *Grew* ſuppoſes, That the chief governing Principle in the Juices of Plants is, the *Saline* or *Salt*; which *ſaline Principle* is to be underſtood as a general Term. The *vegetable Salts* ſeem to be four, *viz.* the *Nitrous*, the *Acid*, the *Alkaline*, and the *Marine*.

The *nitrous Salts* ſeem by Nature to be aſſign'd chiefly to the Growth of Plants; and the other three *Salts* are exhibited by the ſeveral Ways of reſolving the Principles of a Plant.

Salt is accounted good for cold Lands, becauſe the Nature of it is ſuch, that the drier and hotter it is kept, the more it keeps its own Body, and does not turn to Water; and when it ſtands in a cold moiſt Place, then in a little Time it diſſolves to Water; and when it is turn'd to Water, then it is fit for the Nouriſhment and Feeding of Seeds, eſpecially Annuals.

The Reaſon why *Salt*, viz. *Salt-water*, is accounted a Feeder of Seeds or Plants, is, that it has been often obſerv'd, that *Salt* falling on a Board, *&c.* will be long a drying; and if it has been dry'd by Heat, Dews or Rain will make it moiſt again, and then it ſteams forth, and that is it which nouriſhes all Plants: But if it be upon a hot and dry Ground, late in the *Spring*, and dry Weather comes, then it does not, nor can, yield its Steam or Fume.

Pigeons Dung is by many eſteem'd good for cold Lands, becauſe it is hotter and ſalter than any other Dung, it being natural to Pigeons to eat *Salt*; for they fly to the Sea-ſide early on Mornings to pick up that *Salt* which the Heat of the Sun makes by drying up the Salt-water, and leaves upon the Sand.

The Reverend Dr. *Hales*, in his excellent Treatiſe of *Vegetation*, obſerves, That Plants of a leſs durable Texture, as they abound with a greater Proportion of *Salt* and *Water*, which is not ſo ſtrongly attracting as *Sulphur* and *Air*, ſo they are the leſs able to endure the Cold: And as Plants are obſerved to have a greater Proportion of *Salt* and *Water* in them in the *Spring* than in *Autumn*, ſo they are more eaſily injured by Cold in the *Spring* than in a more advanced Age, when their Quantity of Oil is increaſed, with their greater Maturity.

Whence we find that Nature's chief Buſineſs in bringing the Parts of a Vegetable, eſpecially its Fruit and Seed, to a Maturity, is to combine together, in a due Proportion, the more active and noble Principles of *Sulphur* and *Air*, that chiefly conſtitute Oil, which in its moſt refined State is never found without ſome Degree of *Earth* and *Salt* in it.

SALVIA; [ſo called of *Salvus*, or *Salus Vitæ*, i. e. the *Health of Life*] Sage.

The *Characters* are;

It hath a labiated Flower, conſiſting of one Leaf, whoſe Upper-lip is ſometimes arched, and ſometimes hooked; but the Under-lip (or Beard) is divided into three Parts, bunching out, and not hollowed, as the Clary; *out of the Flower-cup riſes the Pointal, attended, as it were, by four Embryo's, which afterwards become ſo many Seeds, which are roundiſh, ſhut up in a Husk, which was before the Flower-cup: To which may be added, that the Stamina do ſomewhat reſemble the* Os Hyoidis.

The *Species* are;

1. Salvia *major, an ſphacelus Theophraſti. C. B. P.* The greater or common Sage.

2. Salvia *nigra. C. B. P.* Common Red Sage.

3. Salvia *major, foliis ex viridi & albo variegatis. Boerh. Ind.* The greater Sage, with Leaves variegated with White and Green.

4. Salvia *foliis verſicoloribus. C. B. P.* Party-coloured Sage.

5. Salvia *latifolia ſerrata. C. B. P.* Broad-leav'd notch'd Sage.

6. Salvia *latifolia ſerrata, foliis ex albo variegatis.* Broad-leav'd Sage, with variegated Leaves.

7. Salvia *abſinthium redolens. J. B.* Worm-wood Sage.

8. Salvia *minor aurita, & non aurita. C. B. P.* Sage of Virtue.

9. Salvia *minor, foliis variegatis. H. R. Par.* Sage of Virtue, with ſtrip'd Leaves.

10. Salvia *Orientalis latifolia abſinthium redolens, flore carneo magno. Boerh. Ind.* Broad-leav'd Eaſtern Sage ſmelling like Worm-wood, with a large Fleſh-colour'd Flower.

11. Salvia *Orientalis latifolia hirſutiſſima viſcoſa pinnata, flore & calice purpureis, inodora. Boerh. Ind.* Eaſtern Sage, with broad, hairy, clammy-wing'd Leaves, with a purpl Flower and Flower-cup, without Smell.

12. Salvia *Africana fruteſcens, folio ſcorodoniæ, flore violaceo. H. A.* Shrubby African Sage, with a Wood Sag Leaf, and a Violet-colour'd Flower.

13. Salvi

13. SALVIA *Africana fruteſcens, folio ſubrotundo, glauco, flore aureo magno. H. A.* Shrubby African Sage, with roundiſh Sea-green Leaves, and a large golden Flower.

14. SALVIA *Orientalis abſinthium redolens, foliis pinnatis, flore carneo, elatior. Sher.* Eaſtern Upright Wormwood Sage, with winged Leaves, and a Fleſh-colour'd Flower.

15. SALVIA *Hiſpanica, folio lavendulæ. Tourn.* Spaniſh Sage, with a Lavender Leaf.

There are ſeveral other *Species* of this Plant, which are preſerved in ſome curious Botanick Gardens abroad; but thoſe here mentioned are what I have obſered in the *Engliſh* Gardens.

The firſt Sort tho' the moſt common in many Parts of *Europe*, yet is but rarely to be ſeen in the *Engliſh* Gardens; but the red Sort is moſt commonly cultivated in this Country, which many Perſons ſuppoſe to be only a Variety of the common Sort; but it conſtantly preſerves its Difference when rais'd from Seeds, as I have two or three times experimented; ſo that I don't ſcruple to make it a diſtinct *Species*, ſince its Difference from the common is much greater than in ſome of the other Sorts of *Sage*, particularly the *Sage of Virtue* and the *Lavender-leav'd Sage*; both which, when cultivated in a good Soil, are ſo nearly alike, as not to be diſtinguiſhed by the beſt Botaniſts. This *Red Sage*, the *Wormwood Sage*, and *Sage of Virtue* are the principal Sorts which are cultivated for Uſe in *England*; though the *Broad-leav'd Sage* is much preferable to the *Sage of Virtue* for Tea, it giving the Water a much more grateful Flavour, and is eſteem'd to be of a leſs drying Quality; ſo that moſt Perſons, who are Lovers of *Sage-Tea*, do prefer this for that Purpoſe.

All the Sorts of *Sage* (except the eleventh Sort, which is but annual) may be propagated by planting Cuttings or Slips, during any of the *Summer* Months, obſerving to water and ſhade them until they have taken Root; after which they may be taken up, and planted where they are deſigned to remain, which ſhould always be upon a dry Soil, and where they may have the Benefit of the Sun; for if they are planted on a moiſt Soil, or in a ſhady Situation, they are very ſubject to be deſtroy'd in *Winter*; nor will theſe Plants endure the Cold ſo well, when planted upon a rich Soil, as thoſe which have a barren, dry, rock Soil, which is the Caſe of moſt of the Verticillate Plants. The Side-ſhoots and Tops of theſe Plants may be gathered in the *Summer*, and dried, if deſigned for Tea, otherwiſe they are beſt taken green from the Plants for moſt other Uſes.

The twelfth, thirteenth and fourteenth Sorts are ſomewhat tender, therefore theſe muſt be planted into Pots fill'd with freſh, light, ſandy Earth; and in Winter muſt be removed into the Conſervatory, where they ſhould be plac'd as near the Windows as poſſible, that they may have a great Share of freſh Air whenever the Seaſon is mild; for if they are too much drawn, they ſeldom flower well, and make but an indifferent Appearance: In Summer they muſt be expos'd amongſt other Exotick Plants in ſome well ſhelter'd Situation, for they are pretty hardy, and do only require to be ſhelter'd from Froſt and ſtrong Winds. Theſe Plants muſt be often refreſh'd with Water, (eſpecially in warm Weather) otherwiſe they will ſhrivel and decay; and they ſhould be tranſplanted at leaſt twice every *Summer*, becauſe their Roots do greatly increaſe; which, if confin'd in the Pots too long, will turn mouldy, and decay. The other Oriental Sorts are hardy enough to endure the Cold of our ordinary Winters in the open Air, provided they are planted in a dry Soil, and a warm Situation.

Theſe Plants may alſo be propagated by ſowing their Seeds in the *Spring* upon a Bed of freſh Earth, obſerving to keep the Ground clear from Weeds until the Plants are come up; when they ſhould be tranſplanted into Beds of freſh Earth, and treated as thoſe rais'd from Cuttings or Slips.

SALVIA AGRESTIS; *vide* Scordium.

SAMBUCUS; [ſo call'd of *Sambuca*, which was a muſical Inſtrument made of this Wood, uſed by the Ancients. Others derive the Name from one *Sandix*, who found out the Virtues of this Tree] The Elder-Tree.

The *Characters* are;

The Branches are full of Pith, having but little Wood; the Flowers are monopetalous, divided into ſeveral Segments, and expand in form of a Roſe; theſe are for the moſt part collected into an Umbel, and are ſucceeded by ſoft ſucculent Berries, having three Seeds in each.

The *Species* are;

1. SAMBUCUS *fructu in umbella nigro. C. B. P.* Common Elder, with black Berries.

2. SAMBUCUS *fructu in umbella viridi. C. B. P.* Common Elder, with greeniſh Berries.

3. SAMBUCUS *fructu albo. Lob.* The white-berried Elder.

4. SAMBUCUS *racemoſa rubra. C. B. P.* The Mountain red-berried Elder.

5. SAMBUCUS *laciniato folio. C. B. P.* The Cut *or* Parſley-leav'd Elder.

6. SAMBUCUS *vulgaris, foliis ex luteo variegatis.* The blotch'd-leav'd Elder.

7. SAMBUCUS *humilis, ſive Ebulus. C. B. P.* Dwarf-Elder *or* Danewort.

The firſt of theſe Trees is very common in the Hedges in moſt Parts of *England*, but the ſecond and third Sorts are more rare; theſe are propagated for the ſake of their Berries, which are by ſome Perſons uſed for making Wine, and for other Purpoſes. The fourth Sort is leſs common in *England* than either of the former, it being only to be found in ſome curious Gardens at preſent. The fifth and ſixth Sorts are preſerved for the Variety of their Leaves, by ſuch as are curious in collecting the various Kinds of Trees and Shrubs.

All theſe Sorts may be eaſily propagated from Cuttings, or by ſowing their Seeds; but the former being the moſt expeditious Method, is generally practiſed. The Time for planting of their Cuttings is any time from *September* to *March*, in the doing of which there needs no more Care than to thruſt the Cuttings about ſix or eight Inches into the Ground, and they will take Root faſt enough, and may afterwards be tranſplanted where they are to remain, which may be upon almoſt any Soil or Situation; they are extreme hardy, and if their Seeds are permitted to fall upon the Ground, they will produce a Plenty of Plants the ſucceeding *Summer*.

Theſe Trees are often planted for making Fences, becauſe of their quick Growth, but as their Bottoms become naked in a few Years, ſo they are not ſo proper for that Uſe; neither would I recommend them to be planted near Habitations, becauſe at the Seaſon when they are in Flower, they emit ſuch a ſtrong Scent, as will occaſion violent Pains in the Heads of thoſe who abide long near them; beſides, the crude Parts which are continually perſpired through their Leaves, are accounted unwholſome, tho' the Leaves, Bark, and other Parts, are greatly eſteem'd for many Uſes in Medicine.

The *Dwarf-Elder* is found wild in ſome Counties of *England*, but near *London* it is propagated in Gardens for Medicinal Uſe; though very often the Herb-women in the Markets do give the tender Shoots of the *Elder-tree* inſtead of this, to ſuch Perſons as can't diſtinguiſh them aſunder.

This Plant mutiplies exceeding faſt by its creeping Root, which, if permitted to run, will ſoon overſpread a large Spot of Ground; the Off-ſets of theſe Roots may be tranſplanted any time from *September* to *March*, and will grow in any Soil or Situation, but ſhould be allowed Room to ſpread, for if they are planted near other Plants, they will over-run and deſtroy them.

SAMOLOIDES.

The *Characters* are;

It hath a Flower conſiſting of one Leaf, which is cut into four Parts almoſt to the Bottom, and expands in form of a Star. In the Centre of the Flower ariſes the Pointal, which is ſurrounded at Bottom by a Number of ſlender Threads, which are expanded, and accompanied by four Chives. This Pointal afterward becomes an oblong Seed-veſſel, which is bivalve, and contains flat Seeds.

We know but one *Species* of this Plant; which is,

SAMOLOIDES *quæ capraria Curaſavica, Cabritta vulgô dicta. H. A. Boerh. Ind. alt. Weſt-Indian* Thea, *vulgô.*

This Plant is very common in *Jamaica*, and ſeveral other Places in the *Weſt-Indies*, where it hath been by ſome People dried and uſed as Thea, from whence it had the Name. In *Curaſao* the Goats feed on this Plant, from whence the Inhabitants gave it the Name of *Cabritta*. But at preſent it is not uſed by any of the Inhabitants of *America*, ſo far as I can learn.

This Plant is preſerved by the Curious in Botany, for Variety-ſake; but as there is no great Beauty in its Flowers, ſo it is ſeldom preſerved in other Gardens. It is propagated by Seeds, which ſhould be ſown on a Hot-bed early in the *Spring*; and when the Plants are about two Inches high, they ſhould be tranſplanted on another Hot-bed, about four or five Inches aſunder, where they ſhould have a large Share of Air in warm Weather, and muſt be frequently watered. In this Bed the the Plants may remain until they have obtained a large Share of Strength, when they ſhould be tranſplanted into Pots, and plunged into a moderate Hot-bed to promote their taking Root; and after they are well ſettled in the Pots, they may be placed in the Stove, or in an airy Glaſs-caſe, where they may be ſheltered from Cold, but they muſt have a large Share of freſh Air in warm Weather; for if they are expoſed abroad, they will not thrive, nor perfect their Seeds. In *June* theſe Plants will begin to flower, and in *Auguſt* they will perfect their Seeds, and the Plants will live thro' the Winter, provided they are placed in a warm Stove; but as they produce ripe Seeds the firſt Year, ſo it is not worth incumbring the Stove with them in *Winter*.

SAMOLUS, Round-leav'd Water Pimpernel.

The *Characters* are;

It hath a wheel-ſhaped Flower, conſiſting of one Leaf, which is cut into ſeveral Segments; the Pointal ariſes from the Empalement, and is fixed like a Nail in the Centre of the Flower; which uniting with the Empalement, is turned into a Fruit or Pod, opening at the Top, and incloſing many ſmall Seeds.

We have but one *Species* of this Plant; which is,

Samolus *Valerandi. J. B.* Round-leaved Water Pimpernel.

This Plant grows wild in ſwampy Places, where the Water uſually ſtands in *Winter*; and is ſeldom preſerved in Gardens; it is an annual Plant, which flowers in *June*, and the Seeds are ripe in *Auguſt*: at which Time, whoever hath a mind to cultivate this Plant, ſhould ſow the Seeds on a moiſt Soil, where the Plants will come up, and require no farther Care, but to keep them clear from Weeds.

SAND, as Dr. *Boerhave* defines it, is Earth properly ſo called, which is foſſil Body, neither diſſoluble by Fire, Water, nor Air, inſipid and untranſparent, more fuſible than Stone, ſtill friable, and containing uſually a Share of Fatneſs.

Dr. *Liſter* divides the *Engliſh* Sands into two Claſſes; the firſt, *ſharp* or *rag Sand*, conſiſting of ſmall tranſparent Pebbles, naturally found on the Mountains, and not calcinable: Theſe he farther divides into *fine* and *coarſe*, and ſub-divides each according to the Colours, into white, grey, reddiſh, brown, &c.

The ſecond, *ſoft* or *ſmooth*, which he ſub-divides into that with flat Particles broke from Lime-ſtones, that with Silver-like Particles, and that with Gold-like Particles.

As to *Sand*, its Uſe is to make the clayey Earth fertile, and fit to feed Vegetables, &c. for Earth alone, we find, is liable to coaleſce, and gather into a hard coherent Maſs, as is apparent in Clay; and Earth thus imbodied, and, as it were, glued together, is no way diſpoſed to nouriſh Vegatables: But if with ſuch Earth, Sand, &c. *i. e.* hard Cryſtals, (which are not diſſolvable in Water, and ſtill retain their Figure) be intermixed, they will keep the Pores of the Earth open, and the Earth itſelf looſe and incompact, and by that means give room for the Juices to aſcend, and for Plants to be nouriſhed thereby.

Thus a Vegetable, planted either in Sand alone, or in a fat Glebe, or Earth alone, receives no Growth or Increment at all, but is either ſtarved or ſuffocated; but mix the two, and the Maſs becomes fertile. In effect, by means of *Sand* the Earth is render'd, in ſome manner, organical; Pores and Interſtices being hereby maintained, ſomething analogous to Veſſels, by which the Juices may be conveyed, prepared, digeſted, circulated, and at length excerned and thrown off into the Roots of Plants.

Grounds that are ſandy and gravelly, do eaſily admit both of Heat and Moiſture, but then they are liable to theſe Inconveniencies; that they let them paſs too ſoon, and ſo contract no Ligature, or elſe retain it too long, eſpecially where there is a Clay Bottom, and by that means it either parches or chills too much, and produces nothing but Moſs and cancrous Infirmities; but if the *Sand* happens to have a Surface of good Mould, and a Bottom of Gravel or looſe Stone, though it do not hold the Water, it may produce a forward ſweet Graſs, and though it may be ſubject to burn, yet it quickly recovers itſelf with the leaſt Rain.

Sea-ſand is accounted a very good Compoſt for ſtiff Ground, for it effects the two Things following, *viz.* It makes way for the Tree or Seed to root in ſtiff Ground, and makes a fume to feed it.

Sand indeed is apt to puſh the Plants, that grow upon it, early in the *Spring*, and make them germinate near a Month ſooner than thoſe that grow upon Clay, becauſe the Salts in the *Sand* are at full Liberty to be raiſed, and put into Motion upon the leaſt Approach of the Warmth of the Sun; but then, as they are haſty, they are ſoon exhal'd and loſt.

SANGUIS DRACONIS; *vide* Palma,

SANICULA; [ſo called of *ſanando, healing*, becauſe it is good in many Diſtempers] Sanicle.

The *Characters* are;

It is an umbelliferous Plant, whoſe Flower conſiſts of five Leaves placed orbicularly, but are generally bent back to the Centre of the Flower, reſting on the Empalement, which becomes a Fruit compos'd of two Seeds, that are gibbous and prickly on one Side, but plain on the other; ſome of the Flowers are always barren.

There is but one *Species* of this Plant at preſent in *England*; *viz.*

Sanicula *officinarum. C. B. P.* Sanicle *or* Self-heal.

This Plant is found wild in Woods and ſhady Places in moſt Parts of *England*, but being a Medicinal Plant, may be propagated in Gardens for Uſe: It may be increaſed by parting of the Roots, any time from *September* to *March*; but it is beſt to do it in *Autumn*, that the Plants may be well rooted before the dry Weather in *Spring* comes on: They ſhould have a moiſt Soil, and a ſhady Situation, in which they will thrive exceedingly.

SANTOLINA; [ſo called on account of its great Virtue, *q. Sancta Herba*, i. e. the *Holy Herb*] Lavender Cotton.

The *Characters* are;

It hath a globoſe floſculous Flower, conſiſting of many Florets, divided into ſeveral Segments, ſitting on the Embryo, contained in the intermediate little Leaves, hollowed like a Gutter, and a ſquamous hemiſpherical Empalement; the Embryo afterwards becomes a Seed, not at all furniſhed with Down. To theſe Notes muſt be added, larger Flowers than thoſe of Wormwood and Southernwood, and alſo the whole Face of the Plant.

The *Species* are;

1. Santolina *foliis teretibus. Tourn.* Common Lavender Cotton.
2. Santolina *flore majore, foliis villoſis & incanis. Tourn.* Lavender Cotton, with a larger Flower, and hoary Leaves.
3. Santolina *foliis Ericæ vel Sabinæ. Tourn.* Green-leav'd Lavender Cotton, with a Scent like Ointment.
4. Santolina *foliis Cypreſſi. Tourn.* Cypreſs-leav'd Lavender Cotton.
5. Santolina *repens & caneſcens. Tourn.* Creeping and hoary Lavender Cotton.
6. Santolina *foliis minus incanis. Tourn.* Lavende Cotton, with leſs hoary Leaves.
7. Santolina *foliis obſcure virentibus, flore aureo. Tourn* Lavender Cotton, with dark-green Leaves, and a golde Flower.
8. Santolina *foliis Roriſmarini, major. Tourn.* Greater Lavender Cotton, with Roſemary Leaves.
9. Santolina *vermiculata Cretica. Tourn.* Vermiculated Lavender Cotton of Candy.

The firſt of theſe Plants is cultivated in Gardens for Medicinal Uſe; as is the third, for furniſhing Balconies, an other little Places in and near the City, by way of Ornament: but the other Sorts are rarely to be found, but in th Gardens of thoſe who are curious in Botanical Studies.

Moſt of theſe Plants may be cultivated ſo as to becom Ornaments to a Garden, particularly in ſmall Boſquets Ever-green Shrubs; where, if theſe are artfully intermixe with other Plants of the ſame Growth, and placed in th front Line, they will make an agreeable Variety; eſpecially if Care be taken to trim them twice in a *Summer*, keep them within Bounds; otherwiſe their Branches are ap to ſtraggle, and, in wet Weather, to be borne down an diſplaced, which renders them unſightly; but when the are kept in Order, their hoary and different-coloured Leav will have a pretty Effect in ſuch Plantations.

Theſe Plants may be propagated by planting Slips Cuttings of any of the Kinds during the *Spring*, which ſhou be put into a Border of light, freſh Earth, and watered and ſhaded in hot dry Weather, until they have taken Root; after which they will require no farther Care, but to keep them clear from Weeds 'till *Auguſt*, when they ſhould be carefully taken up and tranſplanted where they are deſigned to remain: But if the Ground is not ready by that time to receive them, it will be proper to let them remain in the Border until *Spring*; for if they are tranſplanted late in *Autumn*, they are liable to be deſtroyed by a little Cold in *Winter*.

Theſe Plants are very hardy, and if planted in a lean, gravelly, or ſandy dry Soil, will continue many Years, and reſiſt the Cold very well: But if they are in a wet or rich Soil, they are often deſtroyed in *Winter*.

SAP: The Notion of the *Sap*'s Circulation, was entertained by ſeveral Authors much about the ſame Time, without any Communication from one another; particularly M. *Major* a Phyſician of *Hambourg*, M. *Perrault*, *Mariotte*, and *Malpighi*. It has met, however, with ſome conſiderable Oppoſers, particularly the excellent M. *Dodart*, who could never be reconciled to it.

One of the great Arguments for it is, That the ſame Experiments of Ligature and Inciſion, which evince a Circulation of the Blood in Animals, ſucceed in the like Manner in Plants, particularly in ſuch as abound with *Sap*, as the *Great Tithymale*, *Milk-thiſtle*, &c. if the Ligature be faſtened tight round the Stem, the Part above it is found to ſwell very conſiderably, and that below it a little; whence it appears, that there is a Juice aſcending from the Root, and likewiſe another deſcending from the Branches; and that the latter is thicker than the former, which quadrates exactly with the common Syſtem; the Juice being ſuppoſed to ariſe in capillary Veſſels, in form of a ſubtil Vapour, which condenſed in the Extremes of the Plant by the Neighbourhood of the cold Air, turns back in form of a Liquor, thro' the more patent Pipes of the inner Bark.

M. *Dodart*, inſtead of the ſame Juices going and returning, contends for two ſeveral Juices; the one imbibed from the Soil digeſted in the Root, and from thence tranſmitted to the Extremes of the Branches, for the nouriſhing of the Plant; the other received from the Moiſture of the Air entering in at the Extremities of the Branches: So that the aſcending and deſcending Juices are not the ſame.

One of his chief Arguments is, That if two Trees of the ſame Kind be tranſplanted in one Day, after firſt cutting off their Roots and Branches, and if, after they have taken Root again, ſome of the new Shoots put forth each Year be cut off one of them, it will not thrive half ſo well, notwithſtanding its Root and Trunk being entire as the other.

This he conceives to be a Proof of the Plant's deriving Nouriſhment by the Branches, and concludes it to be of an aerial Nature, becauſe formed of the Moiſture of the Air, Dew, &c. whereas that imbibed from the Soil is terreſtrial, &c. *Hiſt. de l' Acad. Roy. Ann.* 1709.

The Humour or *Sap* of a Plant, then, is a Juice furniſhed by the Earth, and changed into the Plant, conſiſting of ſome foſſil Parts, other Parts derived from the Air and Rain, and others from putrefied Animals, Plants, &c. conſequently in Vegetables are contained all Kinds of Salts, Oil, Water, Earth, &c. and, probably, all Kinds of Metals too, inaſmuch as the Aſhes of Vegetables always yield ſomewhat which the Loadſtone attracts.

This Juice enters the Plant in form of a fine and ſubtile Water; which the nearer it is to the Root, the more it retains of its proper Nature; and the farther from the Root, the more Action it has ſuſtained, and the nearer it approaches to the Nature of the Vegetable.

Conſequently, when the Juice enters the Root, the Bark whereof is furniſhed with excretory Veſſels, fitted to diſcharge the excrementitious Part, it is earthy, watry, poor, acid, and ſcarce oleaginous at all.

In the Trunk and Branches it is further prepared, tho' it ſtill continues acid; as we ſee by tapping or perforating of a Tree in the Month of *February*, when it diſtils a watry Juice apparently acid.

The Juice being here carried to the Germs or Buds, is more concocted; and here having unfolded the Leaves, theſe come to ſerve as Lungs for the Circulation, and further Preparation of the Juice.

For theſe tender Leaves being expoſed to the alternate Action of Heat and Cold, moiſt Nights, and hot ſcorching Days, are alternately expanded and contracted, and the more on account of their reticular Texture.

By ſuch Means is the Juice ſtill further altered and digeſted, as it is further in the *Petala* or Leaves of the Flowers which tranſmit the Juice, now brought to a further Subtilty, to the *Stamina*: Theſe communicate it to the *Farina* or Duſt in the *Apices*, which is, as it were, the Male Seed of the Plant, where having undergone a further Maturation, it is ſhed into the *Piſtil*, which performs the Office of an *Uterus* or Womb; and thus having acquired its laſt Perfection, it gives Riſe to a new Fruit or Plant.

The Root or Part whereby Vegetables are connected to their *Matrix*, and by which they receive their nutritious Juice, conſiſts of an infinite Number of *Vaſa abſorbentia*, which being diſperſed through the Interſtices of the Earth, attract or imbibe the Juices of the ſame: conſequently, every Thing in the Earth that is diſſoluble in Water, is liable to be imbibed; as Air, Salt, Oil, Fumes of Minerals, Metal, &c. and of theſe do Plants really conſiſt.

Theſe Juices are drawn from the Earth very crude; but by the Structure and Fabrick of the Plant, and the various Veſſels they are ſtrained through, become changed, further elaborated, ſecreted, and aſſimilated to the Subſtance of the Plant.

The Motion of the nutritious Juices of Vegetables is produced much like that of the Blood in Animals, by the Action of the Air; in effect, there is ſomething equivalent to Reſpiration throughout the whole Plant.

The Diſcovery of this is owing to the admirable *Malpighi*, who firſt obſerved, that Vegetables conſiſt of two Series or Orders of Veſſels.

1. Such as receive and convey the alimental Juices, anſwering to the Arteries, Lacteals, Veins, &c. of Animals.
2. *Tracheæ* or Air-veſſels, which are long hollow Pipes, wherein Air is continually received and expelled, *i. e.* inſpired and expired; within which *Tracheæ* he ſhews all the former Series of Veſſels are contained.

Hence it follows that the Heat of a Year, nay, of a Day, of a ſingle Hour or Minute, muſt have an Effect on the Air included in theſe *Tracheæ*, *i. e.* muſt rarefy it, and conſequently dilate the *Tracheæ*; whence ariſes a perpetual Spring or Source of Action, to promote the Circulation in Plants.

For by the Expanſion of the *Tracheæ*, the Veſſels containing the Juices are preſſed, and by that Means the Juice contained is continually propelled, and ſo accelerated; by which Propulſion the Juice is continually comminuted, and rendered more and more ſubtile, and ſo enabled to enter Veſſels ſtill finer and finer, the thickeſt Part of it being at the ſame time ſecreted and depoſited into the lateral Cells or *Loculi* of the Bark, to defend the Plant from Cold, and other external Injuries.

The Juice having thus gone its Stage, from the Root to the remote Branches, and even the Flower; and having in every Part of its Progreſs depoſited ſomething both for Aliment and Defence; what is redundant, paſſes out into the Bark, the Veſſels whereof are inoſculated with thoſe wherein the *Sap* mounted; and through theſe it re-deſcends to the Root, and thence to the Earth again; and thus a Circulation is effected.

Thus is every Vegetable acted on by Heat and Cold, during the Day-time eſpecially, while the Sun's Force is conſiderable, the Sap-veſſels ſqueezed and preſſed, and the *Sap* protruded and raiſed, and at length evacuated, and the Veſſels exhauſted; and in the Night again, the ſame *Tracheæ* being contracted by the Cold of the Air, the other Veſſels are eas'd and relax'd, and ſo diſpos'd to receive freſh Food for the next Day's Digeſtion and Excretion.

What Courſe the Juice takes after it is imbibed by the Roots, is not very clear; the Veſſels that take it up, to convey it to the Plant, are too fine to be traced: And hence it has been controverted, whether it is by the Bark, or the Pith, or the Woody Part, that the Plant is fed.

The more common Opinion is for the Bark: The Juice raiſed by the Capillaries of the Wood, is here ſuppoſed to deſcend by the larger Fibres, placed in the inmoſt Part thereof, immediately over the Wood; in which Deſcent the *Sap*, now ſufficiently prepared, adds a Part of its Subſtance to the contiguous Wood, and thus increaſes by *Appoſition*: And hence it may be, that hollow, carious, or rotten Trees, which have neither Pith nor Wood, except juſt enough to ſuſtain the Bark, do grow and bear.

Some contend for the Wood, which they obſerve to conſiſt of ſlender capillary Tubes, running parallel to each other from the Root up the Trunk, being proper to receive in a fine Vapour; in the Aſcent whereof the Fibres become opened, and their Subſtance increaſed: And thus the Trunks of Trees are ſaid to increaſe in their Circumference.

As for the Pith; as the Woody Subſtance of the Trunk becomes more woody, the Pith is compreſſed and ſtreightened to ſuch a Degree, that in ſome Trees it quite diſappears:

Whence it ſeems, that its Office in Vegetation is not very important, ſince its Uſe is not perpetual. By its ſpongeous Subſtance, it ſhould ſeem fitted to receive any ſuperfluous Moiſture tranſuding through the Pores of the Woody Fibres: And if by the Exceſs of ſuch Moiſture, or the like Cauſe, it corrupt and rot, as it frequently happens in *Elms*, the Tree does not grow the worſe for it; which is a convincing Proof it is of no great Uſe.

The learned Dr. *Boerhaave* diſtributes the Juices of Plants into ſix Claſſes.

1. The firſt Claſs comprehends the crude *nutritious Juice*, or the Juices of the Root and Stem of Plants, which are little more than the mere Matter of the Element, as drawn by the Root from the Body it adheres to, whether it be Earth, Water, or the like.

This Juice is found in every Part of the Plant, and therefore may be held an *univerſal Juice*; yet he conſiders it as the Juice of the Root and Stem, becauſe it is chiefly found in them.

This he takes to be a ſubacid watery *Lymph*, without any ſpecifick Taſte or Smell, as not being yet arrived to the Maturity of Oilineſs.

To this Claſs belong thoſe Juices which diſtil in great Abundance from Wounds or Inciſions made in the Woody Parts of Plants; ſuch, *e. g.* is that tart Liquor oozing from the Root of the *Walnut-tree*, when cut off in the Month of *May*.

Such alſo is that limpid, ſubacid Humour, flowing out very plentifully at an Inciſion in the *Birch-tree* in the Month of *March*, to the Quantity of ſeveral Gallons in a few Days.

Such alſo is the Juice iſſuing out of the *Vine* wounded in the *Spring-time*, which always taſtes tartiſh, and ferments like the *Grapes* themſelves.

This Juice may be eſteemed as yet foſſil, being generated of and in the Earth; for the Juice of the Earth being received into the Canals of this Plant, retains its Nature during two or three Circulations; nor does immediately commence a vegetable Juice.

This Claſs of Juices therefore he accounts as the *Chyle of the Plant*, being chiefly found in the firſt Order of Veſſels, *viz.* in the Roots and the Body of the Plant, which anſwer to the Stomach and Inteſtines of Animals.

2. The ſecond Claſs of the *Juices* is that of the Leaves, which are the real Lungs of Plants, and accordingly make a further Change of the Juice, which they receive from the Roots and Stem by Force of the Air. The Juice of Leaves is different therefore from the firſt Juice, as being more ſulphureous, and farther elaborated; not that it derives any Sulphur from the Sun, but that its watery Parts exhaling, it becomes more oily, and leſs volatile.

The Juice of Leaves he diſtinguiſhes into three Kinds:

The firſt is the *Nutritious Juice* of the Leaves; which is that already deſcribed, only further elaborated in the minute *Veſiculæ* of the Leaves, and conſequently leſs and watery, and more oily and ſaccharine.

The ſecond is *Wax*, which exſuding out of the Leaves, adheres to the Surface, and is ſcraped off by Bees with their rough Thighs, to build the Combs withal. This is chiefly afforded by *Lavender* and *Roſemary*; upon the latter of which the *Wax* may be plainly perceived ſticking to the Leaves of it.

The third is *Manna*; not that with which the *Iſraelites* were fed in the Deſart, but a Drug ſold among us: It is an eſſential ſaccharine Salt, exſuding chiefly by Night, and in the *Summar* Seaſon, from the Leaves of a Sort of *Aſh* growing in *Calabria* and *Sicily*, and adhering thereto in the form of a Cruſt, to be gathered the next Morning before the Sun is up.

The like Subſtance is found to exſude from the Leaves of the *Linden-tree* and *Poplar*, in the Heats of *May* and *June*; at which Time they have a Honey Taſte, and are even ſeen with a fatty Juice on them, which, at the Approach of the cold Evening, gathers into Grains.

3. The third Claſs of *Juices* are thoſe of Flowers, or the genital Parts of Plants: In theſe are;

Firſt, a pure, elaborated, volatile *Oil* or *Spirit*, wherein the particular Smell of the Plant or Flower reſides, and which, by reaſon of its extreme Volatility, exhales ſpontaneouſly; inſomuch that if the Flower be laid for ſome time in a warm Place, the odorous Juice or Spirit will be all fled.

The *ſecond*, is the Juice expreſſed from the Flower, which in reality is the ſame with that of the Root and Leaves, only farther prepared; it is thicker than the former, and has ſcarce any Smell at all: Thus, if you bruiſe a *Hyacinth*, or other fragrant Flower, and expreſs the Juice, it will be found altogether inodorous.

The *third*, is the ſweet Juice, called *Honey*, which exſudes from all Flowers; *Aloes*, *Colocynthis*, and other bitter Flowers, not excepted.

In all Male Flowers that have Utricles at the Bottom of the *Petala*, is found a viſcid, ruddy, ſweet Juice in ſome Plenty; and accordingly we ſee the Children gather *Cowſlips*, *Fox-gloves*, *Honeyſuckles*, &c. and ſuck the Honey from them: The Bees too viſit theſe Flowers, and putting in their Proboſcides or Trunks, ſuck out the Honey, and load their Stomachs therewith, to be afterwards diſcharged and laid up in their Combs: So that Honey is a vegetable Juice.

4. The fourth Claſs of *Juices* are thoſe of the *Fruit* and *Seed*; the Preparative whereof is Nature's final Work: Which performed, the Plants ſeem to die for a Time, as all Animals are ſeen to languiſh after the Emiſſion of their *Semen*.

The Juice of the Fruit is like that of the Root, only farther elaborated.

The Juice of the Seed is an *eſſential Oil* or *Balm*, elaborated and exalted to its laſt Perfection. This Juice or Oil is not found in the very Point or Embryo in the Centre of the *Placenta*; all we meet with in that Part is a few fine watery Particles ſecreted from the *Placenta*: But it is in the *Placentula* or *Cotyledones* themſelves, which conſiſt of innumerable little *Folliculi* or Cells, wherein this only Juice is contained, ſerving to defend the *Embryo*, and preſerve it from being corrupted by Water, which, it is well known, will hardly paſs through Oil.

Thus if you take, *e. g. Fennel-ſeed*, cut it through the Middle, and apply it to the Microſcope, you will eaſily perceive a clear ſhining Oil in the Cells of each Lobe, inveſting the tender *Embryo*. Without this Oil it were impoſſible a Seed ſhould live a Month, and much leſs a Year or two, entire and uncorrupted in the Ground.

This Oil is found in the Seeds of all Plants; in ſome, *e. g.* in *Almonds*, *Cocoa-nuts*, &c. in very great Quantities; in others leſs, as *Pepper*, *Arum*, &c. where one would ſcarce imagine any Oil at all.

5. The fifth Claſs of *Juices* is thoſe of the *Bark*; which is an artful Congeries or Bundle of perſpirative Ducts, and abſorbent Veſſels.

Of theſe Juices there are divers Species; for the ſeveral Humours raiſed and diſtributed thro' the Leaves, Flowers, and other Parts of the Plants, have all circulated thro' the Bark, and accordingly are frequently found to diſtil from Wounds made therein. In ſome Caſes, even the whole Plant is no more than Bark, the Pulp having been eat out; as in *Willows*, *Poplars*, &c. which will live a long Time in that State.

The *Bark* ſerves divers Purpoſes; for it not only tranſmits the nutritious Juices of the Plant, but alſo contains divers fat, oily Humours, to defend the fleſhy Parts from the Injuries of the Weather.

6. As Animals are furniſhed with a *Panniculus Adipoſus*, uſually replete with Fat, which inveſts and covers all the fleſhy Parts, and ſcreens them from external Cold; ſo are Plants encompaſſed with a Bark replete with fat Juices, by the Means whereof the Cold is kept out, and in *Winter-time* the *Spiculæ* of Ice prevented from fixing and freezing the Juices in their Veſſels; whence it is that ſome Sorts of Trees remain ever green the Year round, by reaſon their Barks have more Oil than can be ſpent, and exhaled by the Sun, *&c.*

All the Juices of Barks are reducible to eight, *viz.*

1. The crude, acid, watery Juice, called the *Chyle* of the Plant.

2. An oily Juice, which burſting the Bark in the Beginning of the *Summer*, exſudes out of ſeveral Plants; as *Beech*, *Pine*, *Fir*, *Savin*, *Juniper*, and other Ever-greens, and ſuch alone: This Oil diſſolves by the ſmalleſt Degree of Warmth, and is eaſily inflamed, and is that which defends the Plant; which is the Reaſon why theſe Plants will not thrive in very hot Climates.

A *Balm* or fatty Liquor more glutinous than Oil, being nothing but the laſt-mentioned oily Juice, which was more fluid during the *Spring-time*; but which, by the greater Heat of the Sun, has evaporated all its moſt ſubtile Parts, and is converted into a denſer Liquor. Thus the finer Part of Oil of *Olives* being exhaled by the *Summer*'s Warmth, there remains a thick Balſam behind: Thus alſo Oil of *Turpentine*, having loſt its more liquid Parts by Heat, becomes of the thick Conſiſtence of a *Balm*.

4. A *pitchy Juice*, which is the Body of the Oil itſelf, inſpiſſated and turn'd black farther than in the *Balm*: This is the moſt obſerv'd in the *Pine* and *Fir*.

5. *Roſin*, which is an Oil ſo far inſpiſſated, as to become friable in the Cold, and may be procur'd from any Oil, by boiling it much and long. Thus, if *Turpentine* be ſet over a gentle Fire, it firſt diſſolves and becomes an Oil, then a Balſam, then Pitch, and then a Roſin; in which State it is friable in the Cold, fuſible by Fire, and withal inflammable and combuſtible; diſſoluble in Spirit of Wine, but not in Water, which makes the Character of *Roſin.*

Hence the Oil is moſt abundant in the Barks in the *Winter-time*, the *Balſams* in *Summer*, and the *Roſin* in *Autumn.*

6. *Colophony*, which is a Roſin ſtill farther exhauſted of its volatile Part, being pellucid, friable, and approaching to the Nature of Glaſs.

7. *Gum*, which is a Humour exſuding out of the Bark, and, by the Warmth of the Sun, concocted, inſpiſſated, and render'd tenacious, but ſtill diſſoluble in Water, and at the ſame time inflammable, and ſcarce capable of being pulverized.

With this the Gems or Buds of Trees are cover'd in *Winter-time.*

8. A *gummous Roſin*, which is a Humour ſecreted in the Bark, and dry'd by the Heat of the Sun; and thus conſtituting a Body that is partly gummous, and, as ſuch, tenacious and ſoluble in Water; and partly reſinous, and therefore friable, and ſoluble in Oil or Spirit of Wine, but not in Water.

Botaniſts are now generally agreed, that all Plants are furniſh'd with Organs and Parts neceſſary both for Chylification and Sanguification; that they have Veins, Arteries, Heart, Lungs, Adipoſe, Celules, &c. If ſo, it is obvious, that there muſt be ſome Difference between the Juices, which have not undergone the Action of thoſe Parts, and ſuch as have already circulated a number of times.

The ſeveral Juices hitherto recounted, are the firſt or *nutritious Juice*, call'd alſo the *Chyle* of the Plant, under ſuch Alterations and new Modifications as it undergoes in being receiv'd and kept ſome time in Parts of a peculiar Structure; as Leaves, Flowers, Seed, &c. This laſt Juice, call'd the *Blood*, is the ſame nutritious Juice farther altered, by being divers times paſs'd through each of thoſe Parts, and remixed, and at length converted into a new Juice, with Properties different from any of them all.

To prove the Circulation of the *Sap*, Inſtances are brought from Experiments made by Mr. *Fairchild*; as, his *budding* or *inoculating* of a *Paſſion-tree*, whoſe Leaves are ſpotted with yellow, into one of that Sort of *Paſſion-tree* whoſe Leaves are plain; for tho' the Buds did not take, yet after it had been budded a Fortnight, the yellow Spots began to ſhew themſelves about three Feet above the Inoculation; and in a little time after that, the yellow Spots appear'd on a Shoot, which came out of the Ground from another Part of the Plant; which has been accounted a plain Proof of the *Sap*'s Circulation.

Another Inſtance is, another Experiment of the ſame Perſon who grafted the Ever-green *Oak*, or *Ilex*, upon the Common *Oak:* The Leaves of the common *Oak*, which was the Stock, decay'd, and fell off at the uſual Seaſon of the Year; but the Ever-green *Oak*, which was the Cyon grafted upon it, held its Leaves, and continued ſhooting in the *Winter*. From whence it is concluded, that when Trees drop their Leaves, the Sap keeps full in Motion, and is not gone into the Root, as ſome Perſons think.

There are alſo other Experiments of the ſame Perſon, which were ſhewn before the *Royal Society*; as the *New-England Cedar*, or rather *Juniper* grafted on the *Virginian:* And what is taken to prove the Circulation in it, is, the Branch which is grafted was left ſeveral Inches below the Grafting, which continued growing as well as the upper Part above the Grafting.

And alſo another, which is the *Viburnum*, with the Top planted in the Ground, which was become Roots; and the Roots turn'd up which were become Branches: which Plant was in as good a State of growing, as it was in its natural State.

A third Experiment of his was on a *Pear-tree*, which he inarched upon two *Pear* Stocks, in *March* 17$\frac{21}{22}$, having the Roots out of the Ground, and was in a good flouriſhing State, with a Branch in bloſſom, that receives no other Nouriſhment but by the Juices that return down the other two Branches; which tho' it had been done above two Years, yet it continu'd ſhooting Suckers out of the Root; which is eſteem'd as a Proof, that the Branches are as uſual to ſupport the Roots, as the Roots the Branches: And thence he infers, that it is not ſtrange that ſo many Trees miſcarry in planting, when there are no Branches left to the Head to maintain the Circulation to the Roots.

A fourth Experiment he made on the *Cedar* of *Lebanon*, grafted on the *Larix*, which drops its Leaves in the *Winter*, yet maintained the *Cedar* in a flouriſhing Condition, as if it had been on a Tree which held its Leaves all the *Winter*, and the Circulation of Juices ſupported the Graft below the Grafting, and kept it in as good Health as above the Grafting.

In Oppoſition to the Notion of the Circulation of the Sap in Trees like to that in Animal Bodies, the reverend Dr. *Hales*, in his excellent Treatiſe on *Vegetable Staticks*, preſents us with various Experiments, and ſays;

When the Sap has firſt paſs'd through that thick and fine Strainer, the Bark of the Root, we then find it in greateſt Quantities in the moſt lax Part, between the Bark and Wood, and *that* the ſame through the whole Tree.

And if in the early *Spring*, the *Oak*, and ſeveral other Trees, were to be examin'd near the Top and Bottom, when the Sap firſt begins to move, ſo as to make the Bark run, and eaſily peel off, he believes it would be found, that the lower Bark is firſt moiſten'd; whereas the Bark of the top Branches ought firſt to be moiſten'd, if the Sap deſcends by the Bark. As to the *Vine*, he ſays, he is pretty well aſſur'd, that the lower Bark is firſt moiſten'd.

He adds, that it is to be ſeen in many of the Examples of the Experiments he has given in that Book, what Quantities of Moiſture Trees do daily imbibe and perſpire: Now the Celerity of the Sap muſt be very great, if that Quantity of Moiſture muſt moſt of it aſcend to the Top of the Tree, then deſcend and aſcend again, before it is carry'd off by Perſpiration.

The Defect of a Circulation in Vegetables, ſeems, in ſome meaſure, to be ſupply'd by the much greater Quantity of Liquor, which the Vegetable takes in, than the Animal, whereby its Motion is accelerated: For, by the firſt Example he gives, we find the *Sun-flower*, Bulk for Bulk, imbibes and perſpires ſeventeen times more freſh Liquor than a Man every twenty-four Hours.

Beſides, Nature's great Aim in Vegetables being only that the Vegetable Life be carry'd on and maintain'd, there was no occaſion to give its Sap the rapid Motion which was neceſſary for the Blood of Animals.

In Animals, it is the Heart which ſets the Blood in Motion, and makes it continually circulate: but in Vegetables we can diſcover no other Cauſe of the Sap's Motion, but the ſtrong Attraction of the Capillary Sap Veſſels, aſſiſted by the briſk Undulation and Vibrations caus'd by the Sun's warmth, whereby the Sap is carry'd up to the Top of the talleſt Trees, and is there perſpir'd off through the Leaves: But when the Surface of the Tree is greatly diminiſhed by the Loſs of its Leaves, then alſo the Perſpiration and Motion of the Sap is proportionably diminiſhed; as is plain from many of his Experiments.

So that the aſcending Velocity of the Sap is principally accelerated by the plentiful Perſpiration of the Leaves, thereby making Room for the fine Capillary Veſſels to exert their vaſtly attracting Power; which Perſpiration is effected by the briſk rarefying Vibrations of Warmth; a Power that does not ſeem to be any ways well adapted to make the Sap deſcend from the Tops of Vegetables, by different Veſſels, to the Root.

If the Sap circulated, it muſt needs have been ſeen deſcending from the upper Part of large Gaſhes, cut in Branches, ſet in Water, and with Columns of Water preſſing on their Bottoms in long Glaſs Tubes, in his 43d and 44th Experiment.

In both which Caſes it is certain, that great Quantities of Water paſſed through the Stem; ſo that it muſt needs have been deſcending, if the Return of the Sap downwards were by Truſion or Pulſion, whereby the Blood in Animals is return'd through the Veins to the Heart; and that Pulſion, if there were any, muſt neceſſarily be exerted with prodigious Force, to be able to drive the Sap through the finer Capillaries.

So that if there be a Return of the Sap downwards, it muſt be by Attraction, and that a very powerful one, as may be ſeen by many of theſe Experiments, and particularly by Experiment 11th. But it is hard to conceive what and where that Power is, which can be equivalent to that Proviſion Nature has made for the Aſcent of the Sap, in Conſequence of the great Perſpiration of the Leaves.

The Inſtances of the *Jeſſamine-tree*, and of the *Paſſion-tree*, have been look'd upon as Proofs of the Circulation of the Sap; becauſe their Branches, which were far below the inoculated Bud, were gilded. But we have many viſible Proofs in the *Vine*, and other bleeding Trees, of the Sap's receding back, and puſhing forwards alternately, at different times of the Day and Night: And there is great Reaſon to think, that the Sap of all other Trees has ſuch an alternate receding, and progreſſive Motion, occaſion'd by the Alternacies of Day and Night, Warm and Cool, Moiſt and Dry.

For the Sap in all Vegetables does probably recede, in ſome meaſure, from the Tops of the Branches, as the Sun leaves them; becauſe its rarefying Power then ceaſing, the greatly rarefy'd Sap and Air mixed with it, will condenſe, and take up leſs Room than they did, and the Dew and Rain will then be ſtrongly imbib'd by the Leaves, as is probable from Experiment 42, and ſeveral others, whereby the Body and Branches of the Vegetable, which have been much exhauſted by the great Evaporation of the Day, may, at Night, imbibe Sap and Dew from the Leaves.

For by ſeveral Experiments in the 1ſt Chapter of the aforeſaid Book of *Vegetable Staticks*, Plants were found to increaſe conſiderably in Weight in dewy and moiſt Nights.

And by other Experiments on the *Vine*, in the 3d Chapter, it was found, that the Trunk and Branches of *Vines* were always in an imbibing State, caus'd by the great Perſpiration of the Leaves, except in the bleeding Seaſon: but when at Night that perſpiring Power ceaſes, then the contrary imbibing Power will prevail, and draw the Sap and Dew from the Leaves, as well as Moiſture from the Roots.

And we have a further Proof of this in Experiment 12, where, by fixing Mercurial Gages to the Stems of ſeveral Trees which do not bleed, it is found, that they are always in a ſtrongly imbibing State, by drawing up the Mercury ſeveral Inches: Whence it is eaſy to conceive, how ſome of the Particles of the gilded Bud in the inoculated *Jeſſamine* may be abſorb'd by it, and thereby communicate their gilding *Miaſma* to the Sap of other Branches; eſpecially when, ſome Months after the Inoculation, the Stock of the inoculated *Jeſſamine* is cut off a little above the Bud; whereby the Stock, which was the counter-acting Part to the Stem, being taken away, the Stem attracts more vigorouſly from the Bud.

Another Argument for the Circulation of the Sap, is, that ſome ſorts of Graſs will infect and canker the Stocks they are grafted on: But by Experiment 12 and 37, where Mercurial Gages were fixed to freſh-cut Stems of Trees, it is evident, that thoſe Stems were in a ſtrongly imbibing State; and conſequently, the cankered Stocks might very likely draw Sap from the Graft, as well as the Graft alternately from the Stock: juſt in the ſame manner as Leaves and Branches do from each other in the Viciſſitudes of Day and Night.

And this imbibing Power of the Stock is ſo great, where only ſome of the Branches of the Stock will, by their ſtrong Attraction, ſtarve thoſe Grafts; for which Reaſon, it is uſual to cut off the greateſt Part of the Branches of the Stock, leaving only a few ſmall ones to draw up the Sap.

The Inſtance of the *Ilex* grafted upon the *Engliſh Oak*, ſeems to afford a very conſiderable Argument againſt a Circulation: For if there were a free, uniform Circulation of the Sap through the *Oak* and *Ilex*, why ſhould the Leaves of the *Oak* fall in *Winter*, and not thoſe of the *Ilex?*

Another Argument againſt an uniform Circulation of the Sap in Trees, as in Animals, may be drawn from Dr. *Hales*'s 37th Experiment, *viz.* where it was found by the three Mercurial Gages fixed to the ſame *Vine*, that while ſome of its Branches chang'd their State of protruding Sap into a State of imbibing, others continu'd protruding Sap, one nine, and the other thirteen Days longer.

That the Sap does not deſcend between the Bark and the Wood, as the Favourers of a Circulation ſuppoſe, ſeems evident from hence, *viz.* That if the Bark be taken off for three or four Inches breadth quite round, the Bleeding of the Tree above that bared Place will much abate: which ought to have the contrary Effect, by intercepting the Courſe of the refluent Sap, if the Sap deſcended by the Bark.

But the Reaſon of the Abatement of the Bleeding in this Caſe may be well accounted for, from the manifeſt Proof we have in theſe Experiments, that the Sap is ſtrongly attracted upwards by the vigorous Operation of the perſpiring Leaves, and attracting Capillaries: But when the Bark is cut off for ſome Breadth below the bleeding Place, then the Sap which is between the Bark and the Wood below that diſbarked Place is deprived of the ſtrong attracting Power of the Leaves, *&c.* and conſequently the bleeding Wound cannot be ſupply'd ſo faſt with Sap, as it was before the Bark was taken off.

But the moſt conſiderable Objection againſt this progreſſive Motion of the Sap without a Circulation, ariſes from hence, *viz.* That 'tis too precipitate a Courſe for a due Digeſtion of the Sap, in order to Nutrition: whereas in Animals, Nature has provided that many Parts of the Blood ſhall run a long Courſe before they are either apply'd to Nutrition, or diſcharged from the Animal.

But when we conſider, that the great Work of Nutrition in Vegetables, as well as Animals, (I mean, after the Nutriment is got into the Veins and Arteries of Animals) is chiefly carry'd on in the fine Capillary Veſſels, where Nature ſelects and combines, as ſhall beſt ſuit her different Purpoſes, the ſeveral mutually attracting nutritious Particles, which were hitherto kept disjoin'd by the Motion of their fluid Vehicle; we ſhall find, that Nature has made an abundant Proviſion for this Work in the Structure of Vegetables: all whoſe Compoſition is made up of nothing elſe but innumerable fine Capillary Veſſels, and glandulous Portions for Veſicles.

Upon the Whole, he thinks we have, from theſe Experiments and Obſervations, ſufficient Ground to believe that there is no Circulation of the Sap in Vegetables; notwithſtanding many ingenious Perſons have been induc'd to think there was, from ſeveral curious Obſervations and Experiments, which evidently prove, that the Sap does, in ſome meaſure, recede from the top, towards the lower Parts of Plants; whence they were, with good Probability of Reaſon, induced to think that the Sap circulated.

SAPINDUS, The Soap-berry.

The *Characters* are;

It hath a Flower which for the moſt part is compoſed of four Leaves, expanding in form of a Roſe: from whoſe four-leaved Empalement ariſes the Pointal, which afterward becomes a ſpherical Fruit, incloſing a Nut of the ſame Form.

We have but one *Species* of this Plant, which is;

SAPINDUS *foliis coſtæ alatæ innaſcentibus. Inſt. R. H.* The Soap-berry or Soap Appletree.

This Tree is very common in *Jamaica*, *Barbados*, and moſt other Places in the *Weſt-Indies*, where it riſes to the Height of thirty Feet or more; but in *Europe* it is preſerved by thoſe Perſons who are curious in cultivating exotic Plants, for the ſingular Structure of the Leaves, which are very long and narrow, having Borders on each Side, which at about every two Inches have *Pinnæ* or Wings, oppoſite to each other, and terminated by an odd one. The Flowers are produced at the Ends of the Branches, which are ſmall and white, growing in Cluſters. Theſe are ſucceeded by ſpherical brown Berries, about the Size of Cherries, which have very little Pulp, but a brown Skin, covering the Nut, which is round, black and hard. Theſe Nuts were formerly brought into *England* to make Buttons, for which purpoſe they were very proper, becauſe they never crack. The Skin which ſurrounds the Nut, will lather like Soap, and is uſed in *America* to waſh Linen, tho, many People ſay it will burn it, when it is often uſed.

This Plant is propagated by Seeds (which muſt be obtain'd from the Countries, where they naturally grow, for they do not produce Fruit in *Europe*): theſe muſt be put into ſmall Pots, filled with freſh rich Earth, and plunged into a Hot-bed of Tanners-bark. Theſe Pots muſt be frequently watered, otherwiſe the Berries whoſe outer Cover is very hard, will not vegetate. In a Month or five Weeks the Plants will begin to appear, when the Glaſſes of the Hot-bed ſhould be raiſed every Day in warm Weather, to admit freſh Air to the Plants; but if the Nights are cold, the Glaſſes ſhould be covered with Mats every Evening, as ſoon as the Sun is gone off from ſhining on the Bed; and the Plants muſt be frequently refreſhed with Water. In three Weeks or a Month after the Plants appear, they will be fit to tranſplant; when they muſt be ſhaken out of the Pots, and carefully parted, ſo as not to injure their Roots, and each planted into a ſeparate ſmall Pot, filled with light rich Earth, and then plunged into the Hot-bed again, obſerving to ſhade them from the Sun every Day, until they have taken new Root; after which Time they muſt have free Air admitted to them every Day, when the Weather is warm; and the Plants will require to be frequently watered.

After the Plants are well rooted, they will make great Progreſs, ſo as to fill theſe Pots with their Roots in a few Weeks Time: therefore they muſt then be ſhifted into larger Pots; and if the Plants have grown ſo tall as to reach the Glaſſes of the Hot-bed, or be in Danger of having their Leaves ſcorched by the Sun thro' the Glaſſes, they ſhould be removed into the Stove, and plunged into the Bark-bed; where if they are duly watered in warm Weather, they will make great Progreſs, and by the Beginning of *Auguſt*, will have Leaves ſixteen or eighteen Inches long. The firſt Leaves of theſe Plants are very long and narrow, having no *Pinnæ* or Wings to them ; but as the Plants advance, ſo they put out firſt one Wing, then two, and afterwards four ; and in old Plants, they have ſometimes ſix or eight Wings, with an odd Wing at the Top.

Theſe Plants are ſo tender as not to live in the open Air in *England*, even at the warmeſt Seaſon of the Year: therefore they ſhould be kept conſtantly in the Stove plunged into the Bark-bed, where they muſt be kept very warm in *Winter* ; but in *Summer*, they muſt have a large Share of freſh Air in warm Weather, with which theſe Plants will thrive very faſt, and they may be expected to flower, tho' for the ſingular Form of the Leaves, they deſerve a Place in the Stove.

SAPONARIA ; *vide* Lychnis.

SAPOTA, The Mammee Sapota.

The *Characters* are ;

It hath a roſe-ſhaped Flower, conſiſting of ſeveral Leaves, which are placed in a circular Order ; from whoſe Empalement ariſes the Pointal, which afterward becomes a large oval ſoft fleſhy Fruit, incloſing an oblong pointed Stone or Fruit, which is finely poliſhed, having a rough Fiſſure on one of the Edges, of an Aſh-colour.

The *Species* are ;

1. Sapota *fructu turbinato minori. Plum. Nov. Gen.* Sapota with a leſſer Fruit, ſhaped like a Top.
2. Sapota *fructu ovato major. Plum. Nov. Gen.* Sapota with a larger oval Fruit.

The Name of *Sapota* is what theſe Fruit are called by the Natives of *America* ; to which ſome add the Apellation of Mammee. But there is no other Name given to theſe Fruits by the *Engliſh*, ſince they have ſettled in the *Weſt-Indies* ; ſo far as I can learn.

The firſt of theſe Trees is common about *Panama*, and ſome other Places in the *Spaniſh Weſt-Indies* ; but is not to be found in any of the *Engliſh* Settlements in *America*. The ſecond Sort is very common in *Jamaica*, *Barbados*, and moſt of the Iſlands in the *Weſt-Indies*, where the Trees are planted in Gardens for their Fruit, which is by many Perſons greatly eſteemed.

Theſe Trees grow in *America* to the Height of thirty five or forty Feet, having a ſtrait Trunk, covered with an aſh-colour'd Bark. The Branches are produced on every Side, ſo as to form a regular Head: theſe are beſet with Leaves, which are a Foot in Length, and near three Inches broad. The Flowers, which are produced from the Branches, are of a cream Colour ; when theſe fall away, they are ſucceeded by large oval or top-ſhaped Fruit, which are covered with a browniſh Skin, under which is a thick Pulp of a ruſſet Colour, very luſcious, called natural Marmelade, from its likeneſs to Marmelade of Quinces.

As theſe Trees are Natives of very warm Countries, ſo they cannot be preſerved in *England*, unleſs they are placed in the warmeſt Stoves, and managed with great Care. They are propagated by planting of the Stones ; but as theſe will not keep good long out of the Ground, ſo the ſureſt Method to obtain theſe Plants, is to have the Stones planted in Tubs of Earth, as ſoon as they are taken out of the Fruit, and theſe Tubs placed in a Situation where they may have the morning Sun, and kept duly watered. When the Plants come up, they muſt be ſecure from Vermin, and kept clear from Weeds ; but ſhould remain in the Country, till they are about a Foot high, when they may be ſhipped for *England* ; but they ſhould be brought over in the *Summer* Seaſon, and, if poſſible, Time enough for the Plants to make good Roots after they arrive. During their Paſſage they muſt have ſome Water, while they continue in a warm Climate ; but as they come into colder Weather, they ſhould have very little Moiſture ; and they muſt be ſecured from Salt-water, which will ſoon deſtroy the Plants, if it gets at them.

When theſe Plants arrive in *England*, they ſhould be carefully taken out of the Tubs, preſerving ſome Earth to their Roots, and planted into Pots filled with freſh Earth, and then plunged into a moderate Hot-bed of Tanners-bark, obſerving, if the Weather is hot, to ſhade the Glaſſes with Mats every Day, to ſcreen the Plants from the Sun, until they have taken new Root, obſerving not to water them too much at firſt, eſpecially if the Earth in which they come over is moiſt ; becauſe too much Water is very injurious to the Plants, before they are well rooted ; but afterward they muſt have plenty of Water in warm Weather, and they muſt have a large Share of Air admitted to them ; otherwiſe their Leaves will be infeſted with Inſects, and become foul ; in which caſe they muſt be waſhed with a Sponge, to clean them, without which the Plants will not thrive.

In the Winter theſe Plants muſt be placed in the warmeſt Stove, and in cold Weather they ſhould have but little Water given to them, tho' they muſt be frequently refreſhed, when the Earth is dry ; eſpecially, if they retain their Leaves all the Winter, they will require a greater Share of Water, than when they drop their Leaves ; ſo that this muſt be done with Diſcretion, according to the State in which the Plants are. As theſe Plants grow in Magnitude, ſo they ſhould be ſhifted into Pots of a larger Size ; but they muſt not be over-potted, for that will infallibly deſtroy them.

SARRACENA, The Side Saddle-flower.

The *Characters* are ;

It hath a Flower conſiſting of ſeveral Leaves, which are placed circularly, and expand in form of a Roſe, and reſting in a many-leaved Empalement ; from the middle ariſes the Pointal, which is membranaceous, and ſhaped like a Hood, and afterwards becomes a roundiſh Fruit divided into five Cells, which contain oblong Seeds.

We have but one *Species* of this Plant ; which is,

Sarracena *Canadenſis, foliis cavis & auritis. Inſt. R. H.* Canady Sarracena, with hollow eared Leaves.

This ſtrange Plant is a Native of *New England*, *Virginia*, and ſeveral Places in *North America* ; where it grows on Bogs, and ſuch Places where the Waters uſually ſtand in *Winter*. The Leaves of this Plant ariſe from the Root every *Spring*, being eight or nine in Number, which are ſmall at the Bottom, but ſwell larger toward the Top, and are hollow like a Pitcher, having a Sort of an Appendage at the Top, ſomewhat reſembling a Flap, ſo that in theſe Leaves there is commonly a large Quantity of Water contained. Between the Leaves ariſes the Flower-ſtem, which hath ſeveral roſaceous Flowers growing on the Top, which are ſucceeded by roundiſh Fruit.

The Name was given to this Plant by Dr. *Tournefort*, in Honour of Dr. *Sarrazin* a curious Botaniſt, who ſent the Plant from *Canady* to Dr. *Tournefort* at *Paris*.

As this Plant grows on Bogs, ſo it is very difficult to cultivate in *England* ; for altho' the *Winters* are much more ſevere in the Places of their natural Growth, than they generally are in *England*, yet their *Summers* being much warmer, they thrive much better, and produce their Flowers and Fruit annually ; whereas it is with great Difficulty they are kept alive for a Year or two in *England* ; and they have not yet flowered in this Country, that I could ever learn. By the Appearance of ſome Plants, which I received from *New England*, there ſeem to be two Sorts of this Plants, one of which is much larger than the other ; but as I never had an Opportunity of ſeeing theſe Plants in Flower, ſo I cannot determine any thing with Certainty about them.

The only Method to obtain theſe Plants is to procure them from the Places of their Growth, and to have them taken up with large Balls of Earth to their Roots, and planted in Tubs of Earth, which muſt be conſtantly watered during their Paſſage, otherwiſe they will decay before they arrive : and there is little Probability of raiſing theſe Plants from Seeds, ſo that young Plants ſhould be taken up to bring over, which are more likely to ſtand here, than thoſe which have flowered two or three times. When the Plants are brought over, they ſhould be planted into pretty large Pots, which ſhould be filled with ſoft ſpongy Earth, mixed with rotten Wood, Moſs and Turf, which is very like the natural Soil in which they grow. Theſe Pots muſt be conſtantly ſupplied with Water, and placed in a ſhady Situation in *Summer* ; but in the *Winter* they muſt be covered with Moſs, or ſheltered under Frame, otherwiſe they will not live in this Country, tho' they have much more ſevere Froſt in the Countries where they naturally grow ; but there they are covered with Snow, which may be a great Protection to them. With this Management I have kept ſome of theſe Plants alive two Years, but they made very little Progreſs.

SATUREJA, [ſo call'd, becauſe it is ſaid to cauſe a *Satyriaſmus* or *Priapiſmus* ; for it very much excites to venery, and carries a Warmth to the *Membrum Virile*] Savory.

The *Characters* are ;

It is a Plant of the verticillate Kind, with a labiated Flower, whoſe Upper-lip (or Creſt) is divided into two Parts ; but the Lower-lip (or Beard) is divided into three Parts, the middle Part being crenated : Theſe Flowers are produced from the

Wings of the Leaves, in a looſe Order, and not in Whorles or Spikes, as are moſt of this Tribe of Plants.

The *Species* are;

1. SATUREJA *ſativa. J. B.* Garden *or* Summer Savory.
2. SATUREJA *montana. C. B. P.* Winter Savory.
3. SATUREJA *Virginiana. Par. Bat.* Virginian Savory.

The firſt of theſe Plants is annual, and is propagated by ſowing of the Seeds upon a Bed of light freſh Earth in *March*; and when the Plants are come up, they muſt be tranſplanted into other Beds, placing them about four or five Inches aſunder each Way; obſerving to do this in moiſt cloudy Weather, becauſe at ſuch times the Plant will ſoon take Root: but if the Seaſon ſhould prove hot and dry, they muſt be diligently watered until they have taken Root; after which they will require no farther Care, but to keep 'em clear from Weeds; and in *July* they will flower, at which time they will be cut for medicinal Uſe: but thoſe Plants which are left will produce ripe Seeds in *September*, provided the *Autumn* be favourable.

The *Winter Savory* is an abiding Plant, and may be propagated by Slips or Cuttings; which, if planted in a Bed of light freſh Earth in the *Spring*, and carefully watered, will take Root in a ſhort time, and may then be tranſplanted where they are to remain. This Plant ſhould have a dry Soil, in which it will endure the Cold very well, as may be ſeen by its growing in ſome Places upon the Tops of Walls, where it defies the ſevereſt Cold of our Climate.

Theſe Plants were formerly more cultivated in *England* than at preſent, they being very little in Uſe to what they were formerly, when they enter'd moſt Diſhes of Soups, *&c.* but at preſent they are very little uſed in the Kitchen, and are chiefly cultivated for medicinal Uſe.

SATYRION; *vide* Orchis.

SAVIN; *vide* Sabina.

SAVORY; *vide* Satureja.

SAURURUS, Lizards-tail.

The *Characters* are;

It hath an apetalous Flower, conſiſting of two Chives, which open two ways, and are full of very ſmall Powder (or Farina.) The Embryo reſts between the two Chives, which afterward becomes an oval ſoft Fruit, incloſing a ſingle Seed. To theſe Notes muſt be added, The Flowers and Fruit are fixed to one Axis, ſo as to reſemble the Tail of a Lizard.

The *Species* are;

1. SAURURUS *racemoſus, ſeu botryites major. Plum. Nov. Gen.* Greater branching Lizards-tail.
2. SAURURUS *racemoſus, ſeu botryites minor. Plum. Nov. Gen.* Leſſer branching Lizards-tail.
3. SAURURUS *cauda adunca. Plum. Nov. Gen.* Lizards-tail, with a crooked Tail.
4. SAURURUS *foliis plantagineis, cauda breviori. Plum. Nov. Gen.* Lizards-tail, with plantain Leaves, and a ſhorter Tail.
5. SAURURUS *botryites major, foliis plantagineis. Plum. Nov. Gen.* Greater cluſtered Lizards-tail, with plantain Leaves.
6. SAURURUS *foliis amplis rotundis & umbilicatis. Plum. Nov. Gen.* Lizards-tail, with large round umbilicated Leaves.
7. SAURURUS *foliis amplis cordatis, non umbilicatis. Plum. Nov. Gen.* Lizards-tail, with large heart-ſhaped Leaves, not umbilicated.
8. SAURURUS *procumbens minor botryites, folio carnoſo cordato. Plum. Nov. Gen.* Smaller creeping cluſtered Lizards-tail, with a fleſhy heart-ſhaped Leaf.
9. SAURURUS *alius humilis, folio carnoſo ſubrotundo. Plum. Nov. Gen.* Low Lizards-tail, with a roundiſh fleſhy Leaf.
10. SAURURUS *repens, folio orbiculari, nummulariæ facie. Plum. Nov. Gen.* Creeping Lizards-tail, with a round Leaf, having the Appearance of Moneywort.
11. SAURURUS *repens tryphyllus, folio rotundo. Plum. Nov. Gen.* Creeping three-leaved Lizards-tail, with a round Leaf.
12. SAURURUS *cauliculis maculoſis, repens. Plum. Nov. Gen.* Creeping Lizards-tail, with a ſpotted Stalk.
13. SAURURUS *fruteſcens, lauro-ceraſi folio, fructu breviore & craſſiore. Houſt.* Shrubby Lizards-tail, with a laurel Leaf, and a ſhorter and thicker Fruit.
14. SAURURUS *arboreſcens latifclia villoſa fructu gracili. Houſt.* Tree-like Lizard's-tail, with a broad, hairy Leaf, and a ſlender Fruit.

The ſeven Sorts firſt mentioned grow to be ſhrubby, and riſe to the Height of four or five Feet, having Leaves placed alternately on their Branches. The *Iulus* comes out from the Wings of the Leaves, which is ſhaped like a Lizard's Tail, from whence they had their Names. By ſome they are called Long Pepper, from the Reſemblance the *Iuli* bear to the Long Pepper: But the Fruit of theſe are not uſed, nor have they the taſte of Pepper. Theſe Sorts were diſcovered to grow in *Jamaica*, by the late Dr. *Houſtoun*; and ſome of them are deſcribed by Sir *Hans Sloane*, in his Natural Hiſtory of *Jamaica*.

The eighth, ninth and tenth Sorts are Plants of humbler Growth: Theſe trail on the Ground, and emit Roots from their Joints, which faſten themſelves into the Earth, whereever it is looſe, by which Method they ſpread to a great Diſtance. The Leaves and Stalks of the ninth Sort are very thick and ſucculent, and remain always green.

The eleventh and twelfth Sorts are creeping Plants, which faſten themſelves to Trees; by which Means they riſe to the Height of eight or ten Feet, faſten their Roots into the Bark of the Trees, and receive Part of their Nouriſhment from thence.

All theſe twelve Sorts were diſcovered by Father *Plumier* in the *Weſt-Indies*, who has figured and deſcribed them in his Hiſtory of *American* Plants; but ſeven of them were before deſcribed by Sir *Hans Sloane*, in his Natural Hiſtory of *Jamaica*.

The two laſt Sorts were diſcover'd by the late Dr. *Houſtoun* at *La Vera Cruz*, from whence he ſent Samples of them into *England*. Theſe two Sorts grow much larger than either of thoſe before-mentioned.

Some of theſe Plants are called by the Inhabitants of *Jamaica*, *Spaniſh Elder*, from their being jointed, and their Branches having a great deal of Pith in them. Others of them, eſpecially thoſe which have Leaves ſhaped like a Heart, are called *Santa Maria* Leaves.

Theſe Plants moſt of them grow in moiſt ſhady Places, in the warmeſt Parts of *America*, where many of them root into the decayed Trunks of Trees, and rotten Wood, (eſpecially thoſe which trail) and thereby they propagate faſter than by Seeds; for as they emit Roots at almoſt every Joint, ſo each of theſe will make a ſeparate Plant.

But as theſe Plants are too tender to bear the open Air in this Climate, ſo they muſt be preſerved in a Stove, where the Air may be kept to a moderate Temperature for Heat; and if they are placed in the Bark-bed, and their Branches permitted to trail on the Surface of the Bark, the Plants will ſend forth Roots at every Joint, and faſten themſelves ſtrongly into the Bark, ſo will thrive exceeding faſt, and produce their Flowers and Fruit.

The Seeds of theſe Plants, when brought from abroad, ſeldom ſucceed in *England*; ſo that the moſt proper Method to obtain the Plants, is to have ſome of their Cuttings planted into Boxes of Earth, in the Countries where they naturally grow; and when they are well rooted, they may be ſent over to *England*, with Directions given to the Perſons to whoſe Care they are entruſted, not to let them have too much Water, (eſpecially when they come into a cool Climate) becauſe Moiſture then will be very prejudicial to them. They muſt alſo be carefully guarded againſt the Salt-water, which will infallibly deſtroy them, if it be ſuffered to come to them. When the Plants arrive in *England*, they ſhould be carefully taken out of the Boxes, and each planted into a ſeparate ſmall Pot, filled with light freſh Earth, and then plunged into a moderate Hot-bed of Tanners-bark, obſerving to ſhade them from the Sun at firſt, until they have taken Root; after which Time they ſhould have freſh Air admitted to them, in Proportion to the Warmth of the Seaſon: But in *Winter* they muſt be kept pretty warm, otherwiſe they will not live in this Country.

The ſureſt Method to make theſe Plants thrive in *England*, is, to plunge the Pots into the Bark-bed in the Stove, and to ſuffer the Branches of the creeping Kinds to trail on the Surface of the Bed, where they will ſtrike Roots into the Tan, and will thrive exceedingly. Theſe Plants merit a Place in every Collection of Plants, for their remarkable Leaves, and the ſingular Structure of their Branches, as alſo for the Oddneſs of their Flowers and Fruit, which are, for the moſt part, produced from the Wings of the Leaves.

SAXIFRAGA, [ſo called, *q. Saxa, Stones*, and *frangens*, Lat. *breaking*; becauſe, as *Bauhinus* ſays, the Juice of it being drank, breaks the Stone in the Reins and Bladder: But the Truth of it is doubted. Others derive it from its growing on ſtony Mountains; as growing out of the Clefts of the Stones] Saxifrage.

The *Characters* are;

The Flower conſiſts of ſeveral Leaves, placed orbicularly, which expand in form of a Roſe; out of whoſe multifid Flower-cup riſes the Pointal; which commonly ends in two Horns, and afterwards turns, together with the Flower-cup, into a roundiſh Fruit, which has likewiſe two Horns and two Cells, which are full of ſmall Seeds.

The *Species* are;

1. SAXIFRAGA *rotundifolia alba. C. B. P.* White round-leafed Saxifrage.
2. SAXIFRAGA *rotundifolia alba, flore pleno. Boerh. Ind.* White round-leafed Saxifrage, with a double Flower.
3. SAXIFRAGA *Alpina ericoides, flore cœruleo. Tourn.* Mountain Heath-like Sengreen, with a blue Flower.
4. SAXIFRAGA *ſedi folio, flore albo, multiflora. Tourn.* Many-flower'd Saxifrage, with an Houſeleek Leaf, and a white Flower, *commonly called* Pyramidal Sedum.
5. SAXIFRAGA *ſedi folio anguſtiore, ſerrato. Tourn.* Saxifrage with a narrow, ſerrated, Houſeleek Leaf.
6. SAXIFRAGA *ad folia bulbos gerens. C. B. P.* Saxifrage bearing Bulbs at the Wings of the Leaves.
7. SAXIFRAGA *verna annua humilior. Inſt. R. H.* Dwarf ſpring annual Saxifrage, *commonly called* Rue-leafed Whitlow-graſs.
8. SAXIFRAGA *muſcoſa, trifido folio. Inſt. R. H.* Moſſy Saxifrage, with a trifid Leaf, *commonly called* Mountain Sengreen, *or* Ladies Cuſhion.
9. SAXIFRAGA *tridactylites Alpina, pallide lutea. Inſt. R. H.* Mountain Saxifrage, of a pale yellow Colour, with a Leaf cut into three Segments.
10. SAXIFRAGA *tridactylites Alpina minor & villoſa. Inſt. R. H.* Smaller hairy Saxifrage of the Alps, with a Leaf cut into three Segments.
11. SAXIFRAGA *alba petræa Ponæ. Inſt. R. H.* White Rock Saxifrage.
12. SAXIFRAGA *ſedi folio, Pyrenaica ſerrata. Inſt. R. H.* Pyrenean Saxifrage, with a ſawed Houſeleek Leaf.
13. SAXIFRAGA *foliis ſubrotundis ſerratis. Inſt. R. H.* Saxifrage with roundiſh ſawed Leaves.
14. SAXIFRAGA *Alpina ſedi foliis crenatis aſperis. Inſt. R. H.* Saxifrage of the Alps, with rough notched Leaves like Houſleek.
15. SAXIFRAGA *foliis oblongo-rotundis dentatis, floribus compactis. Raii Syn. Ed.* 3. Saxifrage with an oblong, roundiſh, indented Leaf, and the Flowers growing in cloſe Bunches.
16. SAXIFRAGA *montana pyramidata, folio longiore. Inſt. R. H.* Mountain pyramidal Saxifrage, with a long Leaf.
17. SAXIFRAGA *Pyrenaica lutea minima, ſedi foliis denſiſſime congeſtis. Inſt. R. H.* The leaſt yellow Pyrenean Saxifrage, with Houſleek Leaves growing very cloſe together.
18. SAXIFRAGA *Alpina minima, foliis cæſiis, deorſum incurvis. Inſt. R. H.* The leaſt Saxifrage of the Alps, with Sky-coloured Leaves which bend downward.
19. SAXIFRAGA *Alpina lutea, ſedi folio. Inſt. R. H.* Yellow Saxifrage of the Alps, with a Houſleek Leaf.
20. SAXIFRAGA *Pyrenaica tridactylites latifolia. Inſt. R. H.* Pyrenean Saxifrage, with broad Leaves, cut into three Segments.
21. SAXIFRAGA *Cantabrica latifolia tridactylites rigidior. Inſt. R. H.* Broad ſtiff-leafed Saxifrage of *Biſcay*, with Leaves cut into three Segments.
22. SAXIFRAGA *tridactylites Pyrenaica, pallidè lutea, minima. Inſt. R. H.* The leaſt pale yellow Saxifrage of the Pyrenees, with Leaves, cut into three Segments.
23. SAXIFRAGA *Pyrenaica, foliis partim integris, partim trifidis. Inſt. R. H.* Pyrenean Saxifrage, with Leaves partly intire, and partly cut into three Segments.
24. SAXIFRAGA *Pyrenaica minima, lutea, muſco ſimilis. Inſt. R. H.* The leaſt yellow Saxifrage of the Pyrenean Mountains, reſembling Moſs.
25. SAXIFRAGA *annua Cretica minima, hederaceo folio. Tourn. Cor.* The leaſt annual Saxifrage of Candia, with an Ivy Leaf.
26. SAXIFRAGA *Penſylvanica, floribus muſcoſis. Hort. Elth.* Saxifrage of Penſylvania, with greeniſh Flowers, growing branchy.

The firſt of theſe Plants is very common in moiſt Meadows in divers Parts of *England*, and is rarely cultivated in Gardens. This is what the *College of Phyſicians* have directed to be uſed in Medicine under the Title of *White Saxifrage*, to diſtinguiſh it from *Meadow Saxifrage*, which is an umbelliferous Plant, of a very different Nature and Appearance from this.

The ſecond Sort is a Variety of the firſt, which was found wild by Mr. *Joſeph Blind*, Gardener at *Barns*, who tranſplanted it into his Garden, and afterwards diſtributed it to ſeveral curious Perſons; ſince which Time it hath been multiplied ſo much, as to become a very common Plant in moſt Gardens near *London*, where it is commonly planted in Pots to adorn Court-yards, *&c.* in the *Spring*.

This Plant is propagated by Off-ſets, which are ſent forth from the old Roots in great Plenty. The beſt Seaſon for tranſplanting them is in *July*, after their Leaves are decay'd, when they muſt be put into freſh undunged Earth, and placed in the Shade until *Autumn*; but in *Winter* they may be expoſed to the Sun, which will cauſe them to flower ſomewhat earlier in the *Spring*. In *April* theſe Plants will flower; and if they are in large Tufts, will at that Time make a very handſome Appearance; for which Reaſon moſt People ſuffer them to remain three or four Years unremov'd, and when they are tranſplanted do always plant them in Bunches, that they may produce a greater Number of Flowers. If theſe Plants are put into the full Ground, they muſt have a ſhady Situation, otherwiſe they will not thrive.

The third Sort is a low, creeping Plant, which lies upon the Surface of the Ground, ſomewhat like Moſs: This grows wild in the Northern Counties of *England*, and is rarely cultivated in Gardens.

The fourth Sort is propagated for the ſake of its ſpecious Flowers: This is brought from the *Alps* and *Pyrenæan* Mountains, where it grows wild. It is uſually planted in Pots filled with freſh light Earth, and in the *Summer* Seaſon placed in the Shade, but in the *Winter* it ſhould be expoſed to the Sun; and all the Off-ſets ſhould be taken off, leaving the Plant ſingle, which will cauſe it to produce a much ſtronger Stem for flowering: For when there are Off-ſets about the old Plant, they exhauſt the Nouriſhment from it, whereby it is rendered much weaker. Theſe Off-ſets muſt be each planted in a ſeparate Half-penny Pot, filled with freſh Earth, in order to ſucceed the older Plants, which generally periſh after flowering: Theſe Off-ſets will produce Flowers the ſecond Year, ſo that there ſhould be annually ſome of them planted, to ſucceed the others. When theſe Plants are ſtrong and healthy, they will produce a Stem of Flowers full three Feet high, which divides into Branches in a pyramidal Order, and are beſet with Flowers from Bottom to Top, ſo as to make a beautiful Figure: And as it uſually flowers in *June*, ſo it is commonly placed in Chimnies or Halls, where it will continue in flower a long Time, provided it have Water duly given it, and will afford an agreeable Proſpect.

The fifth Sort is alſo a Native of the *Alps*, but will grow very well in Gardens: And though the Flowers are not very beautiful, yet, for the Variety of its ſerrated, ever-green Leaves, it may have a Place in every good Garden. This may be propagated by Off-ſets, and requires the ſame Management as the former.

The ſixth Sort here mentioned is a Variety of the common white *Saxifrage*, from which it differs, in bearing ſmall Bulbs at the Leaves. This is not common in *England*, but is found wild on the *Pyrenean* Mountains, and in other mountainous Places in *Spain* and *Italy*: and propagates very faſt by the Bulbs which grow on the Stalks, in the ſame Manner as the fiery Lilly.

The ſeventh Sort is a low annual Plant, which uſually grows on the Tops of Walls, and on dry rubbiſhy Places, and flowers in *April*. This Plant has been eſteemed a very good Remedy for the King's-evil, and other ſcrophulous Diſorders. Mr. *Boyle*, in his Treatiſe concerning the Uſefulneſs of Natural Philoſophy, has recommended this Herb to be infuſed in Small-beer, and drank for ſome Days, which he ſays will cure the King's-evil, without any ſenſible Evacuation, by conſuming the Humour, mitigating the Pain, diſcuſſing the Tumours, and drying up the Ulcers. The Time for gathering of this Herb to dry is in the Middle of *April*, when it is in Flower; for it ſoon after perfects its Seeds, and dies away.

The eighth Sort grows wild in ſeveral Parts of *Yorkſhire*, and other cold Countries. This ſpreads on the Surface of the Ground, and forms itſelf into a roundiſh Tuft, which is exceeding cloſe and ſoft, and has the Appearance of Moſs at a ſmall Diſtance; from whence ſome of the Country People give it the Name of Ladies Cuſhion. This Sort may be propagated in Plenty by its trailing Shoots, which, if they reſt on the Ground, will put out Roots and multiply exceedingly. It loves a moiſt ſhady Situation.

The ninth, tenth, eleventh, ſeventeenth, eighteenth, twentyſecond, twentythird and twentyfourth Sorts are alſo ſmall Plants, which lie cloſe to the Ground, ſomewhat like the eighth Sort; ſo propagate themſelves plentifully, and are all of them very hardy Plants, being Natives of the *Alps*, *Pyrenees*, and other mountainous Places: They require to be planted in a moiſt Soil, and a ſhady Situation; for if they are too much expoſed to the Sun, they will not thrive; nor will they continue long, if they are planted in a rich Soil.

As theſe Plants do not produce very beautiful Flowers, ſo they are ſeldom regarded, and are rarely planted in Gardens, unleſs by ſome Perſons who are curious in Botany, for the ſake of Variety. But yet theſe Plants may be introduced to plant about Rock-work, or between the Joints of ruſtick Buildings, where, if they are in the Shade, they will thrive very well, and have a very good Effect to the Sight: For theſe will ſucceed where Moſs cannot be planted; and having ſo much the Appearance of Moſs, will be by moſt People taken for it at a ſmall Diſtance; and as theſe continue green throughout the Year, ſo they will much better anſwer the Purpoſe.

The twelfth, thirteenth, fourteenth, fifteenth, ſixteenth and nineteenth Sorts have broader Leaves, and appear very much like ſome Sorts of Houſleeks. Theſe are very hardy Plants, being Natives of Northern Countries; ſo muſt be planted in a ſhady Situation, and a poor Soil: but they will grow on drier Places than the former Sorts. Theſe Plants are eaſily propagated by Off-ſets, which they ſend out in great Plenty, and may be adapted to the ſame Purpoſes as the former, to adorn Rock-work, *&c.* and will make a pretty Diverſity.

The twentyfifth Sort is an annual Plant, which was found by Dr. *Tournefort*, in the Iſland of *Crete*, and is by ſome preſerved for the ſake of Variety; but there is no great Beauty in it.

The twentyſixth Sort was brought from *Penſylvania* to Mr. *Peter Collinſon*, who hath diſtributed it to ſeveral Perſons who are curious in preſerving rare Plants. This Sort hath long Leaves, which ſpread on the Surface of the Ground, from between which ariſe the Flower-ſtems, which grow about two Feet high, and branch toward the Top, bearing Cluſters of ſmall greeniſh Flowers. This is propagated by parting of the Roots, and ſhould be planted in a ſhady Situation, where if it is duly watered in dry Weather, it will thrive and flower every Year plentifully, and may be allowed a Place in ſhady Borders, for the ſake of Variety.

SCABIOSA, [ſo called of *Scabies*, Lat. *a Scab*, becauſe this Plant is ſaid to heal the Scab] Scabious.

The *Characters* are;

It hath a floſculous Flower, conſiſting of many unequal Florets, contained in a common Empalement. Some of theſe which occupy the Middle, are cut into four or five Segments; the reſt, which are placed at the Edge, are bilabiated; each of theſe ſit on the Top of an Embryo, which is crowned; and is contained in a proper Empalement, which afterwards becomes a Capſule, either ſimple or Funnel-ſhaped, pregnant with a Seed crowned, which before was the Embryo.

The *Species* are;

1. SCABIOSA *pratenſis hirſuta, quæ officinarum.* C. B. P. Common Field Scabious.

2. SCABIOSA *integrifolia glabra, radice præmorſa.* H. L. Whole-leafed Scabious, *or* Devil's-bit.

3. SCABIOSA *ſtellata, folio non diſſecto.* C. B. P. Starred Scabious, with an undivided Leaf.

4. SCABIOSA *ſtellata, folio laciniato, major.* C. B. P. Greater ſtarred Scabious, with a cut Leaf.

5. SCABIOSA *peregrina rubra, capitulo oblongo.* C. B. P. Red Indian Scabious, with longiſh Heads, *commonly called* Muſk Scabious.

6. SCABIOSA *peregrina, capitulo oblongo, flore carneo.* H. R. Par. Indian or Muſk Scabious, with longiſh Heads, and a Fleſh-coloured Flower.

7. SCABIOSA *peregrina, capitulo oblongo, flore atro-purpureo.* H. R. Par. Indian or Muſk Scabious, with longiſh Heads, and a dark purple Flower.

8. SCABIOSA *peregrina, capitulo oblongo, flore variegato.* H. R. Par. Indian or Muſk Scabious, with oblong Heads, and a variegated Flower.

9. SCABIOSA *Indica prolifera.* H. Edinb. Indian childing Scabious.

10. SCABIOSA *Africana fruteſcens.* Par. Bat. Ic. African ſhrubby Scabious.

11. SCABIOSA *Africana fruteſcens, folio rigido ſplendentem ſerrato, flore albicante.* H. A. African ſhrubby Scabious, with a ſtiff, ſhining, ſerrated Leaf, and a whitiſh Flower.

12. SCABIOSA *Alpina, folio centaurii majoris.* C. B. P. Alpine Scabious, with a greater Centaury Leaf.

13. SCABIOSA *fruticans latifolia alba.* C. B. P. White broad-leafed Shrubby Scabious.

14. SCABIOSA *fruticans latifolia, floribus ad cœruleum inclinantibus.* C. B. P. Broad-leafed ſhrubby Scabious, with Flowers inclining to Blue.

15. SCABIOSA *fruteſcens anguſtifolia alba.* C. B. P. White narrow-leafed ſhrubby Scabious.

16. SCABIOSA *multifido folio, flore flaveſcente.* C. B. P. Scabious, with a variouſly divided Leaf, and a yellowiſh Flower.

17. SCABIOSA *montana glabra, foliis ſcabioſæ vulgaris.* C. B. P. Mountain ſmooth-leafed Scabious.

18. SCABIOSA *montana latifolia non laciniata, rubra & prima.* C. B. P. The firſt red broad-leafed mountain Scabious, not jagged.

19. SCABIOSA *latifolia rubra non laciniata ſecunda.* C.B.P. The ſecond red broad-leafed Scabious, not jagged.

20. SCABIOSA *argentea anguſtifolia.* C. B. P. Narrow ſilver-leafed Scabious.

21. SCABIOSA *Sicula fruticans, laureolæ folio, ſubtus incano.* Inſt. R. H. Shrubby Sicilian Scabious, with a ſpurge Laurel Leaf, hoary underneath.

22. SCABIOSA *fruteſcens foliis leucoii hortenſis.* Hort. Cath. Shrubby Scabious, with Stock-gilly-flower Leaves.

23. SCABIOSA *Cretica fruteſcens, auriculæ urſi folio.* Tourn. Cor. Shrubby Candy Scabious, with a Bear's-ear Leaf.

24. SCABIOSA *fruteſcens, foliis infra integris, flore cœruleo.* Boerh. Ind. Shrubby Scabious, with the lower Leaves intire, and a blue Flower.

25. SCABIOSA *perennis Sicula, flore ſulphureo.* Boerh. Ind. Perennial Sicilian Scabious, with a Brimſtone-coloured Flower.

26. SCABIOSA *ſtellata fruteſcens, leucoii folio minor, unâ alterâve crenâ inciſo.* Flor. Bat. Shrubby ſtarry-ſeeded Scabious, with a ſmaller Stock-gilly-flower Leaf.

27. SCABIOSA *Africana fruteſcens maxima, foliis rugoſis & crenatis minor.* Par. Cat. Greateſt ſhrubby African Scabious, with rough and leſs notched Leaves.

28. SCABIOSA *Africana fruteſcens maxima, foliis tenuiſſimè inciſis.* Boerh. Ind. Alt. Greateſt ſhrubby African Scabious, with Leaves very finely jagged.

29. SCABIOSA *altiſſima annua, foliis agrimoniæ nonnihil ſimilibus.* H. L. The talleſt annual Scabious, with Leaves, ſomething like thoſe of *Agrimony*.

30. SCABIOSA *fraxinellæ foliis.* Inſt. R. H. Scabious with white Dittany Leaves.

31. SCABIOSA *virgæ paſtoris folio.* C. B. P. Scabious with a leſſer Teaſel Leaf.

32. SCABIOSA *Luſitanica, Indicæ ſimilis.* Inſt. R. H. Portugal Scabious, like the Indian one.

33. SCABIOSA *ſtellata Hiſpanica, ampliſſimo folio.* Inſt.R.H. Spaniſh ſtarred Scabious, with a very large Leaf.

34. SCABIOSA *ſtellata annua prolifera.* R. H. Par. Annual proliferous ſtarred Scabious.

35. SCABIOSA *Orientalis ſtellata, foliis variis, flore carneo, ſemifloſculis florum fimbriatis.* Eaſtern ſtarred Scabious, with variable Leaves, and a Fleſh-colour'd Flower, whoſe half-florets are fringed.

The twelve firſt are the principal Sorts which are propagated for the Beauty of their Flowers. The firſt Sort here mentioned grows wild in divers Parts of *England*, upon arable Land; as doth the ſecond in Woods and ſhady Places almoſt every where. The firſt of theſe is what the *College of Phyſicians* have directed to be uſed, under the Title of *Scabious*; though the People who ſupply the Markets do generally bring the ſecond Sort inſtead thereof; but it may be eaſily known therefrom by its hairy, divided Leaves. The ſecond Sort the *College* have directed to be uſed under the Title of *Devil's-bit*, which Name it received from the lower Part of its Root being commonly eaten off.

Both theſe Plants are very common in the Fields and Woods, but may be propagated in Gardens, by ſowing their Seeds in the *Spring* upon a Bed of freſh Earth, and when the Plants are come up, they muſt be tranſplanted into other Beds of freſh Earth, at about eight or ten Inches Diſtance, obſerving to water them until they have taken Root; after which they will require no further Culture, but to keep them clear from Weeds; and the ſecond *Summer* they will flower, and produce Seeds; but their Roots will abide many Years, and may be parted, to propagate the Species.

The third Sort will grow to the Height of four or five Feet, and has a woody Trunk: This is preſerved in Green-houſes in *Winter*, by ſuch as are curious in foreign Plants. It may be propagated by planting Slips or Cuttings in Pots of freſh Earth, during any of the *Summer* Months; which, if placed in a moderate Hot-bed, watered and ſhaded, will take Root in a ſhort Time; after which they may be inured to the open Air by Degrees, into which they ſhould be removed to continue abroad until *October*, when they muſt be carried into Shelter, but muſt have as much free Air as poſſible in mild Weather; for they only require to be protected from hard Froſt, and to be frequently watered. This Plant produces Flowers moſt part of the Year, for which it is chiefly preſerved, tho' the Flowers have not more Beauty nor Scent than the common Field Sort.

The fourth Sort is an annual Plant, which is preſerved in the Gardens of the Curious; but the Flowers of this are very like thoſe of the former Sort, and have no Scent.

The *Indian* or *Muſk Scabious's* are preſerved for the Beauty and ſweet Scent of their Flowers, which continue a long Time: Theſe are propagated by ſowing of their Seeds, the beſt Time for which is about the Latter-end of *May*, or the Beginning of *June*, that the Plants may get Strength before *Winter*; for if they are ſown too early in the *Spring*, they will flower the *Autumn* following; and the *Winter* coming on ſoon, will prevent their ripening Seeds: beſides, there will be fewer Flowers upon thoſe, than if they had remained ſtrong Plants through the *Winter*, and had ſent forth their Flower-ſtems in *Spring*; for theſe will branch out on every Side, and produce a prodigious Number of Flowers, and continue a Succeſſion of them on the ſame Plants from *June* to *September*, and produce good Seeds in Plenty.

The Seeds of theſe Plants ſhould be ſown upon a ſhady Border of freſh Earth; (for if they are ſown upon a Place too much expoſed to the Sun, and the Seaſon ſhould prove dry, few of them would grow). When the Plants are come up, they may be tranſplanted into other Beds or Borders of freſh Earth, obſerving to water and ſhade them until they have taken Root; after which they will require no further Care, but to keep 'em clear from Weeds 'till *Michaelmas*, when they may be tranſplanted into the Middle of the Borders in the Pleaſure-Garden, where the ſeveral Sorts being intermixed, will make an agreeable Variety. They are extreme hardy, being rarely injured by Cold, unleſs they have ſhot up to the flower before *Winter*, but do ſeldom continue after ripening their Seeds.

The two *African* Tree *Scabious's* are abiding Plants, which are preſerved in Pots, and houſed in *Winter*, as the third Sort: Theſe may be propagated by Slips or Cuttings, as the third, and require the ſame Management.

The twelfth Sort is preſerved by ſuch as are curious in collecting Varieties of Plants, but the Flowers have no Scent: however, as it is a hardy Plant, requiring no other Culture than the Common Field Sorts; ſo it may be admitted, for Diverſity, into the Pleaſure-Garden, becauſe it will thrive in ſhady Places, where few other Plants will grow.

The thirteenth, fourteenth, fifteenth, ſixteenth, ſeventeenth, eighteenth, nineteenth, twentieth, twentyfourth, twentyfifth, thirtieth, and thirtyfirſt Sorts, are all of them abiding Plants, which are hardy enough to live in the open Air in *England:* ſo may be managed as hath been above directed for the common Sorts of *Scabious*.

The twentyfirſt, twentyſecond, twentythird, and twentyſixth Sorts, are alſo abiding Plants; but are ſomewhat tenderer than thoſe before mentioned: ſo ſome Plants of each Kind ſhould be kept in Pots, that they may be ſheltered in *Winter* under a common Hot-bed Frame; and the others muſt be planted in warm Borders, otherwiſe they will not live thro' the *Winters* in this Country: and if the Soil in which theſe are planted, is poor and dry, they will grow ſtunted, and bear the Cold much better, than thoſe which are planted in a rich Soil, and grow freely. Thoſe Plants which are in Pots, and are placed in Shelter in *Winter*, muſt have as much free Air as poſſible in mild Weather; otherwiſe they will draw up weak, and appear very unſightly; ſo they ſhould only be covered in very hard Froſts, and continually expoſed in mild Weather.

The twentyſeventh, and twentyeighth Sorts were brought from the *Cape of Good Hope*, ſo are more tender than the former: therefore theſe muſt always be kept in Pots, and in *Winter* ſhould be placed in an airy Glaſs-caſe, where in mild Weather they may have as much free Air as poſſible; they ſhould be frequently watered, for they are very thirſty Plants. In ſevere Froſt they muſt be carefully guarded, but they will bear a little Cold pretty well.

All the ſhrubby Sorts of *Scabious* may be propagated by Cuttings, which may be taken off during any of the *Summer* Months, and ſhould be planted in a ſhady Border, and duly watered in dry Weather, which will promote their taking Root; and then they may be potted, and placed in a ſhady Situation, till they have taken new Root, after which Time they may be placed amongſt other hardy exotic Plants, in a ſheltered Situation, where they may remain until the End of *October*, when they muſt be removed into Shelter. In ſome favourable Seaſons theſe Plants will produce good Seeds in *England*, ſo that the Plants may be raiſed from theſe, by ſowing them in an open Border of light Earth about the middle of *March*; and if the *Spring* ſhould prove very dry, it will be neceſſary to water the Ground now and then, which will forward the Vegetation of the Seed; ſo that the Plants will appear in about three Weeks after the Seeds are ſown. When they come up, they muſt be kept clear from Weeds, and in dry Weather duly watered; and when they are ſtrong enough to tranſplant, they ſhould be planted in Pots, and managed in the ſame Manner as thoſe Plants which are propagated by Cuttings.

The twentyninth, thirtyſecond, thirtythird, thirtyfourth and thirtyfifth Sorts, are annual Plants, which are only propagated by Seeds. Theſe may be managed in the ſame manner as hath been directed for the *Indian Scabious's*.

All the Sorts of *Scabious* continue a long time in Flower, for which they are regarded; for there is no very great Beauty in their Flowers: but as moſt of the hardy Sorts produce Flowers near three Months ſucceſſively, ſo they may be allowed a Place in the Borders of large Gardens, becauſe they require very little Care to cultivate them. And as the ſhrubby Kinds continue in Flower moſt Part of the Year, ſo they make an agreeable Variety amongſt hardy exotic Plants in *Winter*.

SCANDIX, Shepherds Needle or Venus-comb.

The *Characters* are;

It hath a roſe-ſhaped umbellated Flower, conſiſting of ſeveral Petals, which are ranged orbicularly, and reſt on the Empalement; which becomes a Fruit conſiſting of two Parts, having two Seeds, which reſemble a needle, when joined.

The *Species* are;

1. SCANDIX *ſemine roſtrato vulgaris. C. B. P.* Common Shepherds Needle, with beaked Seeds.
2. SCANDIX *Cretica major. C. B. P.* Great Shepherds Needle of *Crete*.
3. SCANDIX *Cretica minor. C. B. P.* Smaller Shepherds Needle of *Crete*.
4. SCANDIX *Orientalis, flore maximo. Tourn. Cor.* Eaſtern Shepherds Needle, with a very large Flower.

The firſt of theſe Plants grows wild amongſt Corn, in moſt Parts of *England*. The ſecond and third Sorts grow wild in the Iſland of *Candia*, and the fourth Sort was diſcovered by Dr. *Tournefort* in the *Levant*.

Theſe Plants are preſerved by the Curious in Botany, for the Sake of Variety; but are ſeldom admitted into other Gardens. The Fruit of theſe Plants, having Beaks, greatly reſemble Cranes Bills at a ſmall Diſtance; but being ranged ſomewhat like the Teeth of a Comb, occaſioned the Name given to it.

They may be propagated by Seeds, which ſhould be ſown in *Autumn*, ſoon after they are ripe, in the Place where they are deſigned to remain, which ſhould be in a ſhady Situation, and when the Plants are come up, they will require no farther Care, but to keep them clear from Weeds. In *June* the Plants will flower, and in the Beginning of *Auguſt* they will perfect their Seeds, and ſoon after decay. But if their Seeds are permitted to ſcatter, the Plants will come up without any manner of Care, and become Weeds in the Garden.

SCILLA, [ſo called of *σκίλλω, to make dry*, becauſe this Plant grows in dry Places; or, as others will have it, of *σκύλλω, I am moleſted*, becauſe the Bulb of this Plant, by its Acrimony, irritates the Parts to which it is apply'd] Squils.

The *Characters* are;

It hath a large, acrid, bulbous Root, like an Onion: *The Leaves are broad: The Flowers are like thoſe of* Ornithogalum, *or the* Starry Hyacinth: *They grow in a long Spike, and come out before the Leaves.*

The *Species* are;

1. SCILLA *vulgaris, radice rubra. C. B. P.* Common Red Squil.
2. SCILLA *radice alba. C. B. P.* The White Squil.

Theſe Plants are very common upon the ſandy Shoars of *Spain* and the *Levant*, from whence their Roots are annually brought to *England*, for Medicinal Uſe. But I was lately inform'd, by a Letter from Dr. *William Stevens*, Profeſſor of Botany at *Dublin*, that the *White Squill* grows in great Plenty upon the Sea-coaſt in the County of *Kerry* in *Ireland*; which is the only Place in which it has been found growing wild in theſe Parts of *Europe*. But altho' theſe Roots are brought over chiefly for Medicinal Uſe, yet are they worthy of being cultivated in every good Garden, for the Beauty of their Flowers, which make a very handſome Appearance when they are ſtrong Roots.

The beſt Time to tranſplant theſe Roots is in *May*, when their Leaves are decay'd: Or if the Roots are brought from Abroad, if they can be procured firm at that Seaſon, or a little after, they ſhould be planted in Pots of light, ſandy Earth, and placed in the Windows of the Green-houſe, where, if they are blowing Roots, they will flower the *July* following.

Theſe Plants muſt be preſerved in Shelter during the *Winter* Seaſon; becauſe, if their Leaves are deſtroy'd by Froſt in *Winter*, the Roots are ſubject to periſh: but in *Summer* they ſhould be expoſed to the open Air, and in dry Weather they muſt be frequently watered, eſpecially during the Seaſon their Leaves are on, or that they are in flower: but when the Roots are in a State of Reſt, they ſhould have but little Moiſture; for Wet at that time will rot them. They are pretty hardy, and do only require to be ſhelter'd from hard Froſt; but muſt have as much free Air as poſſible in open Weather.

SCLAREA, [this Plant is ſo called of σκληρὸς, *hard*, becauſe it has a hard and dry Stalk] Clary.

The *Characters* are;

It is a verticillate Plant with a labiated Flower, conſiſting of one Leaf, whoſe Under-lip (or ~~Creſt) is hooked~~; but the Under-lip (or Beard) is divided into three Parts, the middle Segment being hollow and bifid: Out of the Flower-cup riſes the Pointal, attended by four Embryo's, which afterwards turn to ſo many roundiſh Seeds, incloſed in a Husk, which was before the Flower-cup.

The *Species* are;

1. Sclarea *Tabern. Ic.* Common Garden *Clary*.
2. Sclarea *vulgaris lanuginoſa, ampliſſimo folio. Tourn.* Common Downy *Clary*, with a large Leaf.
3. Sclarea *laciniatis foliis. Tourn. Clary*, with a jagged Leaf.
4. Sclarea *Luſitanica glutinoſa, ampliſſimo folio. Tourn. Portugal Clary*, with a large glutinous Leaf.
5. Sclarea *Indica, flore variegato. Tourn.* Indian *Clary*, with a variegated Flower.
6. Sclarea *rugoſo verrucoſo & laciniato folio. Tourn. Clary* with a rough, warted, and jagged Leaf.
7. Sclarea *glutinoſa, floris lutei variegati barba ampla cava. Boerh. Ind.* Glutinous *Clary*, with a yellow, variegated Flower, having a large hollow Beard, *commonly called* Jupiter's Diſtaff.
8. Sclarea *folio ſalviæ, minor, ſive glabra. Tourn.* Leſſer or Smooth *Clary*, with a Sage Leaf.
9. Sclarea *orientalis, folio Betonicæ acutiſſimo, coma purpuraſcente. T. Cor.* Eaſtern *Clary*, with a ſharp-pointed Betony Leaf, and a purpliſh Top.
10. Sclarea *pratenſis, foliis ſerratis, flore ſuave rubente. Tourn.* Meadow *Clary*, with ſerrated Leaves, and a ſoft red Flower.

The Common *Garden Clary* is chiefly cultivated in *England* for medicinal Uſe; but the other Sorts are preſerved in Botanick Gardens for the ſake of Variety, with many other Sorts of leſs Note: however, thoſe here mentioned are worthy of a Place in large Gardens, where, if they are intermixed among other large-growing Plants, they will afford a pretty Variety, eſpecially the fifth, eighth, ninth, and tenth Sorts, which produce long Spikes of beautiful Flowers, and continue a long time in flower.

All theſe Sorts may be propagated by ſowing of their Seeds upon a Bed of freſh Earth in *March*; and when the Plants are come up, they ſhould be tranſplanted into Beds of freſh Earth, about eight Inches aſunder, obſerving to water 'em until they have taken Root; after which they will require no farther Care, but to keep them clear from Weeds until *Michaelmas*, when they ſhould be tranſplanted into the Places where they are to remain, placing them at a large Diſtance; for they ſpread pretty far, provided the Soil be good. If theſe Plants are planted for a Crop, intended for Medicinal Uſe, they ſhould be planted in Rows two Feet and a half aſunder, and the Plants eighteen Inches diſtant in the Rows: But the other Sorts to be placed in Borders ſhould be planted eight or ten Feet diſtant, being intermixed with other Plants. Some of theſe Sorts will endure many Years, provided they are planted on a freſh Soil, not over moiſt or rich; but others do rarely continue longer than the ſecond Year, periſhing ſoon after they have perfected their Seeds: Theſe ſhould therefore be often renewed from Seeds, to have a Continuance of 'em; but the other Sorts may be increaſed by parting their Roots, the beſt time for which is at *Michaelmas*, when their Stems begin to decay.

SCOLYMUS, The Golden Thiſtle.

The *Characters* are;

The whole Plant hath the Appearance of a Thiſtle: the Flower conſiſts of many Half-florets, which reſt on the Embryo's; each of theſe are ſeparated by a thin Leaf, and on the Top of each Embryo is faſtened a little Leaf. Theſe are contained in a ſcaly Empalement, which incloſes the Seed.

The *Species* are;

1. Scolymus *chryſanthemus. C. B. P.* The golden Thiſtle.
2. Scolymus *Chryſanthemus annuus. A. R. Par.* Annual Golden Thiſtle.
3. Scolymus *Chryſanthemus Africanus procerior. H. R. Par.* Taller *African* golden Thiſtle.

The firſt and ſecond Sorts grow wild in the South of *France* and in *Spain*; but the third Sort is a Native of *Africa*. The firſt and third Sorts are biennial Plants; but the ſecond is an annual, ſo they periſh ſoon after they have perfected their Seeds.

They are propagated by Seeds, which ſhould be ſown in *March*, on a Bed of freſh undunged Earth, in an open Situation; and when the Plants are come up, they ſhould be kept clear from Weeds; and where they grow too cloſe, ſome of them ſhould be pulled out, ſo as to leave thoſe which are deſigned to remain, about two Feet aſunder. This is all the Culture which theſe Plants require; for as they ſend forth tap Roots, ſo they do not bear tranſplanting well: therefore they muſt be ſown where they are to remain, and if they are kept clear from great Weeds, they will thrive very well; and when the Seaſons prove dry, will perfect their Seeds in *Autumn*; but in wet Seaſons they rarely ever produce good Seeds in *England*, which renders it difficult to continue the *Species*, without procuring freſh Seeds from abroad.

Theſe Plants are preſerved by thoſe Perſons who are curious in Botany, for Variety ſake, but are rarely planted in other Gardens.

SCORDIUM, [this Plant takes this Name of Σκόροδον, *Garlick*, becauſe it has the Smell of Garlick] Water-Germander.

The *Characters* are;

The Flowers are like thoſe of Germander, *which are produced from the Wings of the Leaves: The Flower-cup is tubulous; and the whole Plant ſmells like* Garlick.

The *Species* are;

1. Scordium. *C. B. P.* Common Water-Germander.
2. Scordium *alterum, ſive ſalvia agreſtis. C. B. P.* Wild Sage, *vulgo*.
3. Scordium *fruteſcens, folio anguſto ſalviæ flore luteolo. Boerh. Ind.* Shrubby Wild Sage, with a narrow Sage Leaf, and yellowiſh Flowers.

The firſt of theſe Plants grows wild in moiſt Places in the Iſle of *Ely*, in great Plenty; but near *London* it is propagated in Gardens for Medicinal Uſe. This Plant is increaſed by parting the Roots, or from Cuttings or Slips: The beſt Time for this Work is in the Beginning of *March*. Theſe Slips muſt be planted in Beds of moiſt Earth, about four or five Inches aſunder, obſerving to water them well until they have taken Root; after which they will require no further Care but to keep 'em clear from Weeds, and in *July* the Plants will be fit to cut for Medicinal Uſe, being at that time in flower: But it is not proper to tranſplant them every Year, for then the Crop will be ſmaller, therefore every other Year will be ſufficient to renew theſe Beds: nor ſhould they be planted again upon the ſame Ground, but upon a freſh Spot, otherwiſe they will not thrive.

The *Wild Sage* is very common in Woods and ſhady Places in divers Parts of *England*, and is rarely cultivated in Gardens, except by thoſe who are curious in Botany. This may be propagated by ſowing the Seeds in the *Spring*, upon a Bed of freſh Earth; and when the Plants are come up, they ſhould be tranſplanted out, at about a Foot aſunder, upon a light freſh Soil, obſerving to water them until they have taken Root; after which they will require no farther Care but to keep 'em clear from Weeds; for they are extreme hardy and will abide many Years in almoſt any Soil or Situation.

The third ſort is of a more tender Nature, and requires to be ſhelter'd from ſevere Froſt; to which if it be expoſed, it is often deſtroy'd. This may be propagated by ſowing the Seeds as the former: but when the Plants come up, they ſhould be placed in Pots of freſh Earth, and in *Winter* put in an airy Part of the Green-houſe, where they may enjoy the free Air when the Weather is mild; for if they are too much drawn, they are ſubject to mould and decay. In the *Summer* Seaſon they ſhould be expoſed to the open Air, with *Myrtles*, and other foreign Plants, and muſt be frequently refreſh'd with Water.

SCORPIOIDES, [ſo call'd becauſe the Husk being wreathed, reſembles the Tail of a Dragon: It is by ſome called *Campoides* of Καμπὴ, *a Canker-worm*, and Εἶδος, *Form*] Caterpillars.

The *Characters* are;

It hath a papilionaceous Flower, out of whoſe Empalement riſes the Pointal, which afterwards becomes a jointed Pod, convoluted like a Snail, or Caterpillar, having a Seed in each Joint, which is, for the moſt part, of an Oval Figure.

The *Species* are;

1. SCORPIOIDES *bupleuri folio. C. B. P.* The Great Rough Caterpillar.
2. SCORPIOIDES *bupleuri folio, corniculis aſperis, magis in ſe contortis & convolutis. Mor. Hiſt.* Prickly Caterpillar.
3. SCORPIOIDES *bupleuri folio, ſiliquis levibus. Park. Theat.* Smooth-podded Caterpillar.
4 SCORPIOIDES *ſiliqua craſſa. Boelii. Ger. Emac.* Thick-podded Caterpillar.
5. SCORPIOIDES *ſiliqua cochleata & ſtriata Olyſſiponenſis. H. R. Par.* Caterpillar with a cochleated and furrowed Pod.
6. SCORPIOIDES *foliis viciæ, minima. Mor. Hiſt.* The leaſt Caterpillar, with vetch Leaves.

Theſe Plants are preſerved in ſeveral curious Gardens, for their Oddneſs more than for any great Beauty: They are all of them annual Plants, which are propagated by ſowing their Seeds upon a Bed of light freſh Earth; and when the Plants are come up, they ſhould be thinned, ſo as to leave 'em about ten Inches or a Foot aſunder, becauſe their Branches trail upon the Ground; and if they have not Room, they are apt to over-bear each other, and thereby are very often rotted, eſpecially in moiſt Seaſons. The Weeds ſhould alſo be diligently clear'd from 'em, otherwiſe they will grow over, and deſtroy 'em: In *June* theſe Plants will produce ſmall, yellow, papilionaceous Flowers, which are ſucceeded by Pods, ſo much like Caterpillars, that a Perſon at a ſmall Diſtance would imagine they were real Caterpillars feeding on the Plants; and it is for this Oddneſs of their Pods that theſe Plants are chiefly preſerved.

Theſe Plants do ſeldom thrive well if they are tranſplanted; therefore the beſt Method is, to put in three or four good Seeds in each Place where you would have the Plants remain, (which may be in the Middle of large Borders in the Pleaſure-Garden, where being intermix'd with other Plants, they will afford a pleaſing Variety). When the Plants come up, there ſhould be only one of the moſt promiſing left in each Place, which ſhould be conſtantly kept clear from Weeds; and when their Pods are ripe, they ſhould be gathered and preſerved in a dry Place 'till the following *Spring*, in order to be ſown.

The firſt, third, and fourth Sorts are the beſt worth cultivating, their Pods being large and more viſible than the other, and are more in form of a Caterpillar.

SCORZONERA; [of *Eſcorſo*, a *Catalonian* Word, ſignifying a *Viper*, becauſe it is ſaid to be of great Efficacy againſt the Bite of Vipers. Authors write, that the Herb being apply'd, takes away the Venom of the Bite of Vipers. They ſay, that if a Viper be touch'd with this Juice, it languiſhes: And that a Man may touch Vipers ſafely, if his Hand be firſt dipp'd in the Juice of this Plant] Viper's-Graſs.

The *Characters* are;

It hath a ſemi-floſculous Flower, conſiſting of many half Florets, which reſt upon the Embryo's, which are included in one common Empalement, which is ſcaley: The Embryo's do afterwards become oblong Seeds, which are furniſh'd with Down.

The *Species* are;

1. SCORZONERA *latifolia ſinuata. C. B. P.* Common *or* Broad-leav'd *Viper's-Graſs*, with an indented Leaf.
2. SCORZONERA *latifolia altera. C. B. P.* Another Broad-leav'd *Viper's-Graſs.*
3. SCORZONERA *laciniatis foliis. Turn. Vipers-Graſs*, with jagged Leaves.

The firſt of theſe Sorts is what the *College of Phyſicians* have directed for Medicinal Uſe: And it is alſo cultivated for the Uſe of the Kitchen in divers Gardens near *London*; tho' at preſent it is not ſo much propagated as it hath been ſome Years ſince, when it was more commonly brought to the Markets.

The ſecond Sort is equally as good as the firſt for all the Purpoſes for which that is cultivated: but as it is leſs common, ſo it is rarely found in *England*, except in Botanick Gardens, where the third Sort is alſo cultivated for Variety, but is never apply'd to any Uſes.

Theſe Plants may be propagated by ſowing their Seeds in the Spring upon a Spot of light freſh Soil. The beſt Method of ſowing them, is, to draw ſhallow Furrows by a Line about a Foot aſunder, into which you ſhould ſcatter the Seeds, thinly covering them over about half an Inch thick with the ſame light Earth; and when the Plants are come up, they ſhould be thinned where they are too cloſe in the Rows, leaving them at leaſt ſix Inches aſunder; and, at the ſame time, you ſhould hough down all the Weeds to deſtroy them: And this muſt be repeated as often as is neceſſary; for if the Weeds are permitted to grow among the Plants, they will draw them up weak, and prevent their Growth.

There are many People who ſow theſe Seeds promiſcuouſly in a Bed, and afterwards tranſplant them out at the Diſtance they would have them grow: But this is not ſo well as the former Method, becauſe their Roots do commonly ſhoot downright, which, in being tranſplanted, are often broken, ſo that they never will make ſo fair Roots as thoſe which remain in the ſame Place where they are ſown; for when the extreme Part of the Root is broken, it never extends itſelf in Length afterwards, but only ſhoots out into many forked ſmall Roots, which are not near ſo valuable as thoſe which are large and ſtrait. Theſe Roots may be taken up when the Leaves begin to decay, at which time they have done growing; though they may remain in the Ground until *Spring*, and may be taken up as they are uſed: but thoſe which remain in the Ground after *March* will ſhoot up their Flower-ſtems; after which they are not ſo good, being ſticky and ſtrong.

If you intend to ſave Seeds of theſe Plants, you ſhould let a Parcel of the beſt remain in the Places where they grew; and when their Stems are grown to their Height, they ſhould be ſupported with Stakes, to prevent their falling to the Ground, or breaking. In *June* they will flower; and about the Beginning of *Auguſt* their Seeds will ripen, when they ſhould be gathered, and preſerv'd dry 'till the *Spring* following for Uſe.

SCROPHULARIA; [ſo called, on account of its reſembling *Scrophuli*, by its Inequality; not becauſe it is good to cure the *Scrophula* in the Neck, as is vulgarly thought] Figwort.

The *Characters* are;

It hath an anomalous Flower, conſiſting of one Leaf, gaping at both Sides, and generally globular, cut, as it were, into two Lips; under the upper one of which are two ſmall Leaves: The Pointal riſes out of the Flower-cup, which afterwards turns to a Fruit or Husk, with a roundiſh-pointed End, opening into two Diviſions, parted into two Cells, by an intermediate Partition, and full of ſmall Seeds, which adhere to the Placenta.

The *Species* are;

1. SCROPHULARIA *nodoſa fœtida. C. B. P.* Stinking Knobbed-rooted *Figwort.*

2. Scrophularia *aquatica major. C. B. P.* Greater Water *Figwort.*

3. Scrophularia *Hiſpanica, ſambuci folio glabro. Tourn.* Spaniſh *Figwort*, with a ſmooth Elder Leaf.

4. Scrophularia *maxima Luſitanica, ſambuci folio lanuginoſo. Tourn.* Greateſt *Portugal Figwort*, with a woolly Elder Leaf.

5. Scrophularia, *ruta canina dicta vulgaris. C. B. P.* Figwort, *commonly call'd* Dog's-Rue.

6. Scrophularia *ſaxatilis lucida, laſerpitii Maſſilienſis foliis. Boc. Muſ.* Shining Rock *Figwort*, with Leaves like the *Marſeilles* Laſerwort.

7. Scrophularia *glauco folio, in amplas lacinias diviſo. Tourn.* *Figwort* with a Sea-green Leaf, divided into large Segments.

8. Scrophularia *foliis filicis modo laciniatis, vel ruta canina latifolia. C. B. P.* *Figwort*, with Leaves jagged after the manner of Fern, or Broad-leav'd Dog's-Rue.

9. Scrophularia *flore luteo. C. B. P.* Figwort with a yellow Flower.

10. Scrophularia *folio urticæ. C. B. P.* Figwort with nettle Leaf.

11. Scrophularia *betonicæ folio. Inſt. R. H.* Figwort with a betony Leaf.

12. Scrophularia *ſcorodoniæ folio. Mor. Hiſt.* Figwort with a wood-ſage Leaf.

13. Scrophularia *peregrina fruteſcens, foliis teucrii craſſuſculis. Breyn. Cent.* Foreign ſhrubby Figwort, with thick germander Leaves.

14. Scrophularia *minor, Ruta canina dicta. Moriſſ. Hiſt.* Leſſer Figwort, called Dogs rue.

15. Scrophularia *Luſitanica fruteſcens, verbenacæ foliis. Inſt. R. H.* Shrubby *Portugal* Figwort, with vervain Leaves.

16. Scrophularia *Cretica fruteſcens, folio vario craſſiori. Tourn. Cor.* Shrubby Figwort of *Candia*, with a thicker variable Leaf.

17. Scrophularia *Græca fruteſcens & perennis, urticæ folio. Tourn. Cor.* *Greek* ſhrubby and perennial Figwort, with a nettle Leaf.

18. Scrophularia *Epheſia, lunariæ folio, flore rubro. Tourn. Cor.* *Epheſian* Figwort, with a moonwort Leaf, and a red Flower.

19. Scrophularia *Orientalis, foliis cannabinis. Tourn. Cor.* Eaſtern Figwort, with baſtard hemp Leaves.

20. Scrophularia *Orientalis, ampliſſimo folio, caule alato. Tourn. Cor.* Eaſtern Figwort, with a large Leaf, and a winged Stalk.

21. Scrophularia *Orientalis, tiliæ folio. Tourn. Cor.* Eaſtern Figwort, with a lime-tree Leaf.

22. Scrophularia *Orientalis, chryſanthemi folio, flore minimo variegato. Tourn. Cor.* Eaſtern Figwort, with a corn-marygold Leaf, and the leaſt variegated Flower.

The firſt Sort here mentioned grows wild in great Plenty in Woods and other ſhady Places in divers Parts of *England*, and is rarely cultivated in Gardens: but this being the Sort which the *College of Phyſicians* have directed for Medicinal Uſe, under the Title of *Scrophularia Major*, it is by ſome preſerved in their Phyſick-Gardens.

The ſecond Sort is alſo very common in moiſt Places, and by the Sides of Ditches almoſt every-where: This is alſo an officinal Plant, and ſtands in the Catalogue of Simples, under the Title of *Betonica Aquatica*, i. e. *Water-Betony*, becauſe the Leaves are ſomewhat like thoſe of *Betony*.

Theſe two Plants may be eaſily propagated in Gardens, by ſowing their Seeds early in the *Spring* upon a Bed of freſh Earth, in a ſhady Situation; and when the Plants are come up, they ſhould be tranſplanted out into a ſtrong moiſt Soil, about two Feet aſunder, obſerving to water them until they have taken Root; after which they will require no farther Care but to hough down the Weeds between them, from time to time, as they are produced. The ſecond Year theſe Plants will ſhoot up to flower; and if their Stems are ſuffered to remain, they will produce Seeds: but the Herb is generally cut for Uſe juſt as the Flowers begin to open; for if it ſtands longer, the Leaves change, and the whole Plant contains much leſs Juice. Theſe Roots will abide many Years without renewing: but it will be proper to tranſplant them every other Year, otherwiſe their Roots will ſpread over each other, and thereby deſtroy themſelves.

The third and fourth Sorts are very beautiful Plants, being worthy of a Place in every good Garden: Theſe are ſomewhat tenderer than the former Sorts; tho' they will endure the Cold of our ordinary *Winters*, if planted in a light Soil, and a warm Situation. Theſe may be propagated by ſowing their Seeds in the *Spring* upon a Bed of freſh Earth; and when the Plants are come up, they ſhould be tranſplanted into Beds of freſh Earth, at about ſix Inches Diſtance from each other, obſerving to water and ſhade them until they have taken Root; after which they will require no farther Care but to keep them clear from Weeds, and in very dry Weather to refreſh them with Water.

At *Michaelmas* ſome of them may be tranſplanted into the Middle of warm Borders in the Pleaſure-Garden; and the reſt may be planted into Pots fill'd with light freſh Earth, which in *Winter* ſhould be ſhelter'd under a common Hot-bed Frame, where they may be cover'd in froſty Weather; but in mild Weather they ſhould have as much free Air as poſſible. Theſe Plants thus ſhelter'd, will flower very ſtrong in *April*; and if duly watered in dry Weather, will produce ripe Seeds in *July*, which may be gather'd in the Pods, and preſerved for ſowing. The Roots of theſe Plants will abide three or four Years, unleſs deſtroy'd by great Cold, and may be parted, to increaſe them: But theſe Plants which are propagated from Slips do ſeldom flower ſo ſtrong as thoſe produced from Seeds; ſo that it is the beſt way to raiſe every Year ſome from Seeds to ſucceed the old Roots.

The fifth, ſixth, ſeventh, and eighth Sorts are alſo tender, and will rarely endure the Cold of our *Winters* without Shelter, unleſs in ſome very warm Situations; therefore theſe ſhould be planted in Pots fill'd with freſh light Earth, and ſhelter'd in *Winter* as the two former Sorts. Theſe may be propagated either from Seeds, as the former, or from Cuttings; but the former being the beſt way, is generally practis'd; becauſe the Plants rais'd from Seeds do always flower much ſtronger than thoſe produced from Cuttings, and likewiſe grow more regular. Theſe Sorts will abide two or three Years, if defended from Froſt in *Winter*: but if they ſhould continue longer, they are ſeldom ſo beautiful as young Plants; ſo that they ſhould be often renew'd from Seeds.

The ninth, tenth, eleventh, fourteenth, eighteenth and twenty-ſecond Sorts, are biennial Plants, which very rarely live longer than two Years. Theſe ſeldom flower the ſame Seaſon their Seeds are ſown; or if they do, it is generally pretty late in *Autumn*, ſo that they do not produce good Seeds: but when the Plants grow ſhort, and do not put out their Flower-ſtems the firſt Year; they flower very ſtrong early in the following *Summer*, and produce good Seeds. Theſe Sorts are hardy enough to endure the Cold of our ordinary *Winters* very well, provided they are planted in a dry undunged Soil.

The twelfth, thirteenth, fifteenth, ſixteenth, ſeventeenth, nineteenth, twentieth and twenty-firſt Sorts, are abiding Plants, their Roots continuing many Years; and the nineteenth Sort creeps at the Root, ſo that it propagates very faſt that way, as alſo by Seeds, this is an extreme hardy Plant, and will live in almoſt any Soil and Situation; but ſhould not be planted too near other Plants; becauſe it creeps ſo far, as to interfere with ſuch Plants as grow near it.

The other Sorts will endure the Cold of our ordinary *Winters* very well, if they are planted in a ſheltered Situation; and when they are planted in a lean rubbiſhy Soil, they will not grow too freely, ſo will be ſtunted, and will endure a much greater Share of Cold, than when they are planted in a rich Soil, where they become very luxuriant.

All theſe Sorts may be propagated by Seeds, which may be ſown, and the Plants managed in the ſame manner as hath been above directed; and being intermixed with other hardy Plants in a large Garden, will make an agreeable Variety.

SCRUPOSE; full of Gravel-ſtones.

SECALE, [ſo call'd of *Secare*, Lat. *to cut*; becauſe theſe Plants are cut when the Seeds are ripe] Rie.

The *Characters* are;

The Flowers have no Leaves, but conſiſt of ſeveral Stamina, which are produced from the Flower-cup: Theſe Flowers are collected into a flat Spike, and are diſpos'd almoſt ſingly: From the Flower-cup riſes the Pointal; which afterwards becomes an oblong ſlender Seed, inclos'd in a Huſk, which was before the Flower-cup. This differs from Wheat, *in having a flatter Spike, the Awn larger, and more naked.*

The *Species* are;

1. Secale *hybernum, vel majus. C. B. P.* Common *or* Winter *Rie.*

2. SECALE *vernum & minus. C. B. P.* Leſſer *or* Spring *Rie.*

Theſe are all the Sorts of *Rie* which are at preſent known in *England*. The Manner of ſowing and huſbanding theſe Plants being ſo well known to every Farmer, it would be neeleſs to ſay any thing of it in this Place, more than that the firſt muſt be ſown in *Autumn*, as *Wheat:* but the other may be ſown in the *Spring*, at the Seaſon for *Barley*, and will ripen almoſt as ſoon as that which was ſown in *Autumn*; which is a great Advantage in ſuch Countries where it is ſubject to be deſtroy'd in *Winter*.

SECURIDACA, [ſo call'd of *Securis*, Lat. *a Hatchet*; becauſe the Antients fanſied the Seeds of it reſembled a Hatchet] Hatchet-Vetch.

The *Characters* are;

It hath a papilionaceous Flower, out of whoſe Empalement riſes the Pointal, which afterwards becomes an upright, plain, annual, articulated Pod, containing in each Joint a rhomboid Seed, having a Notch on the inner Side.

We have but one *Species* of this Plant in *England*; viz.

SECURIDACA *lutea major. C. B. P.* The Greater Yellow Hatchet-Vetch.

This Plant grows among the Corn in *Spain*, *Italy*, and other warm Countries; but in *England* it is preſerv'd in Botanick Gardens for the ſake of Variety: This may be propagated by ſowing the Seeds in Borders of light freſh Earth in the *Spring*, in the Places where they are to abide; for they ſeldom ſucceed well if they are tranſplanted: They ſhould be allow'd at leaſt two Feet Diſtance, becauſe their Branches trail upon the Ground. In *June* theſe Plants will flower; and in *Auguſt* their Seeds will ripen, when they ſhould be gather'd, and preſerv'd for Uſe. A few of theſe Plants may be admitted into every good Garden for Variety, though there is no great Beauty in their Flowers.

SEDUM, [ſo call'd of *ſedendo*, Lat. *ſitting*; becauſe this Plant does, as it were, ſit upon the Walls where it grows; or of *ſedando*, *appeaſing*, becauſe it appeaſes the Pains of Inflammations] Houſeleek.

The *Characters* are;

The Flower conſiſts of ſeveral Leaves, which are placed orbicularly, and expand in form of a Roſe; out of whoſe Flower-cup riſes the Pointal, which afterwards turns to a Fruit, compos'd, as it were, of many Seed-veſſels, reſembling Huſks, which are collected into a ſort of Head, and full of ſmall Heads.

The *Species* are;

1. SEDUM *majus vulgare. C. B. P.* Common Great *Houſeleek.*
2. SEDUM *minus luteum, folio acuto. C. B. P.* The moſt Ordinary Prickmadam, *or* Sharp-pointed Yellow *Houſeleek.*
3. SEDUM *minus luteum, ramulis reflexis. C. B. P.* Yellow Stonecrop, with reflected Flowers.
4. SEDUM *parvum acre, flore luteo. J. B.* Wall-Pepper, or Stonecrop.
5. SEDUM *minus, à rupe Sancti Vincentii. Raii Syn.* Stonecrop of St. *Vincent*'s Rock.
6. SEDUM *minus, teretifolium album. C. B. P.* White-flower'd Stonecrop, with round-pointed Leaves.
7. SEDUM *minus, circinato folio. C. B. P.* Leſſer Stonecrop, with round Leaves.
8. SEDUM *majus vulgari ſimile, globulis decidentibus. Mor. Hiſt. Houſeleek*, like the Common Sort, throwing off the young ones.
9. SEDUM *montanum tomentoſum. C. B. P.* Mountain Woolly *Houſeleek*, *commonly call'd* Cobweb *Houſeleek.*
10. SEDUM *majus arboreſcens. J. B.* Greater Tree *Houſeleek.*
11. SEDUM *majus arboreſcens, foliis elegantiſſimè variegatis tricoloribus. Boerh. Ind.* Greater Tree *Houſeleek*, with beautiful variegated Leaves.
12. SEDUM *Canarinum, foliis omnium maximis. H. A.* The Greateſt *Houſeleek* of the *Canaries*.
13. SEDUM *Afrum ſaxatile, foliolis ſedi vulgaris, in roſam verè compoſitis. Boer. Ind.* African Rock *Houſeleek*, with ſmall Leaves, like the Common ſort, collected like a Roſe.
14. SEDUM *Afrum montanum, foliis ſubrotundis, dentibus albis ſerratis confertim natis. Boerh. Ind.* African Mountain Houſeleek, with roundiſh, indented, ſerrated Leaves, with white Edges.
15. SEDUM *Africanum fruteſcens, folio longo ſerrato confertim nato. Boerh. Ind.* African ſhrubby Houſeleek, with long, ſerrated Leaves.
16. SEDUM *majus montanum, dentatis foliis, alterum. C. B. P.* Another great Mountain Houſeleek, with indented Leaves.
17. SEDUM *majus montanum, foliis non dentatis, floribus rubentibus. C. B. P.* The great Mountain Houſeleek, with indented Leaves and reddiſh Flowers.
18. SEDUM *teretifolium majus, flore albo. Mor. Hort. R. Blæſ.* Greater Houſeleek, with taper Leaves, and a white Flower.
19. SEDUM *minus, lato & craſſo caule, Portlandicum Belgarum. H. R. Par.* Small Portland Houſeleek, with a broad and thick Stalk.
20. SEDUM *Alpinum roſeum, acuto folio, hæmatodes majus. H. R. Par.* Greater bloody roſe Houſeleek of the Alps, with a ſharp-pointed Leaf.
21. SEDUM *Alpinum roſeum medium, aculeo rubente. H. R. Par.* Middle roſe Houſeleek of the Alps, with reddiſh Prickles.
22. SEDUM *Alpinum roſeum minus, viride & ſubhirſutum. H. R. Par.* Small roſe, green and hairy Houſeleek of the Alps.
23. SEDUM *Alpinum ſubhirſutum, folio longiore. H. R. Par.* Hairy Houſeleek of the Alps, with a longer Leaf.
24. SEDUM *Alpinum ſubhirſutum, corona floris purpuraſcente, diſco viridi. H. R. Par.* Hairy Houſeleek of the Alps, with the Borders of a purpliſh Colour, and the Middle green.
25. SEDUM *minus teretifolium luteum. C. B. P.* Small taper-leafed yellow Houſeleek.
26. SEDUM *minus teretifolium alterum. C. B. P.* Another ſmall taper-leafed Houſeleek.
27. SEDUM *longifolium, citrino flore. Mor. H. R, Blæſ.* Long-leafed Houſeleek, with a citron-coloured Flower.
28. SEDUM *minimum luteum, non acre. J. B.* The ſmalloſt yellow Houſeleek, which is not acrid.
29. SEDUM *minimum non acre, flore albo. Raii Hiſt.* The leaſt Houſeleek, which is not acrid, with a white Flower.
30. SEDUM *Alpinum, flore pallido. C. B. P.* Alpine Houſeleek, with a pale Flower.
31. SEDUM *Alpinum, rubro magno flore. C. B. P.* Alpine Houſeleek, with a large red Flower.
32. SEDUM *Hiſpanum, folio glauco acuto, flore albido. Boerh. Ind. alt.* Spaniſh Houſeleek, with a pointed ſea-green Leaf, and a whitiſh Flower.
33. SEDUM *paluſtre ſubhirſutum purpureum. C. B. P.* Hairy purple marſh Houſeleek.
34. SEDUM *echinatum, vel ſtellatum, flore albo. J. B.* Starry Houſeleek, with white Flowers,
35. SEDUM *echinatum, flore luteo. J. B.* Prickly Houſeleek, with a yellow Flower.

The firſt ſort is very common in *England*, being often planted upon the Tops of Houſes, and other Buildings, where being preſerved dry, it will endure the greateſt Cold of our Climate. This is directed by the *College of Phyſicians* to be uſed in Medicine, as a great Cooler. It may be propagated by planting the Off-ſets (which are produced in great Plenty from the old Plants) any time in *Summer*. It requires to be placed very dry; for if its Roots are moiſt, the Plants will rot in cold Weather.

The ſecond, third, fourth, fifth, ſixth and ſeventh Sorts grow in plenty upon Walls in divers Parts of *England*, where they propagate themſelves by their trailing Branches, ſo as in a ſhort Time to cover the whole Place, provided they are not cut off. The ſixth Sort is alſo preſcribed by the *College of Phyſicians* to enter ſome officinal Compoſitions; but the People who ſupply the Markets do commonly ſell the *Wall-pepper* inſtead of this: Which is a very wrong Practice; becauſe the ſixth Sort is a very cold Herb, and is accordingly directed to be put into cooling Ointments: And the *Wall-pepper* is an exceeding ſharp, acrid Plant, (from whence it received the Name of *Wall-pepper*) which renders it contrary to the Intention of the Phyſician; therefore, whoever makes uſe of theſe Plants, ſhould be very careful to have the right; otherwiſe it is better to uſe the common great ſort, in which they are not ſo liable to be impoſed on.

The fifth ſort is a Native of St. *Vincent's Rock* in *Cornwall*, from whence it hath been taken, and diſtributed into the ſeveral Gardens of ſuch Perſons as are curious in preſerving a Variety of Plants.

Theſe Plants are all extreme hardy, and will thrive exceedingly, if planted in a dry Soil, and an open Situation, where they will propagate themſelves by their trailing Branches, which take Root wherever they touch the Ground.

The eighth and ninth ſorts do propagate themſelves by Off-ſets, in the Manner as the common ſort; though the eighth throws off the young ones from the Top of the old Plants, which falling on the Ground take Root, and thereby are increaſed very plentifully. Theſe are both very hardy; and if planted in a dry rubbiſh Soil will thrive, and endure the ſevereſt Cold of our Climate.

The tenth ſort is propagated by planting Cuttings during any of the *Summer* Months, which ſhould be laid in a dry Place a Fortnight after they are cut from the old Plants, that their wounded Plants may heal over before they are planted, otherwiſe they are ſubject to rot. Theſe ſhould be planted in Pots filled with light, freſh, ſandy Earth, and placed in a ſhady Situation, (but not under the Drip of Trees) obſerving to give them now and then a little Water, when the Earth is dry: But you muſt be very careful not to let them have too much Moiſture, which will rot them.

When they have taken Root, they may be removed into a more open Situation, placing them amongſt other exotick Plants, in a Place where they may be defended from ſtrong Winds, in which Situation they may remain until *Autumn*, when they muſt be removed into the Conſervatory, to be preſerved from Cold in *Winter*, which will deſtroy them. Though they do not require any artificial Heat, but only to be protected from Froſt, yet do they require to have as much free Air as poſſible in mild Weather: therefore the beſt Way of preſerving theſe Plants is to have an airy Glaſs-caſe, in which many ſorts of *Ficoides's*, and other ſucculent Plants, may be intermixed with theſe, where they will thrive much better than if placed amongſt *Oranges*, *Myrtles*, and other Trees in a Green-houſe; becauſe the Perſpiration of thoſe Trees renders the Air of the Place damp; and when the Houſe is cloſely ſhut up, this Air is often rancid, which being imbibed by the *Houſeleeks*, will cauſe their Leaves to fall off, and the Plants will decay ſoon after; whereas in an open airy Glaſs-caſe, where there are none but ſucculent Plants, there will never be near ſo much Damp in the Air; and in ſuch Places they will thrive and flower almoſt every *Winter*, when the Plants have gotten ſufficient Strength. Theſe Plants, in moiſt Weather, will ſend forth long Roots from their Branches, four or five Feet from the Ground: And if the Earth is placed near to theſe Roots they will ſtrike into it, and the Branches may be afterwards ſeparated from the old Plants.

The eleventh ſort is a Variety of the tenth, which was accidentally obtained in the Gardens of the late Dutcheſs of *Beaufort* at *Badmington*, from a Branch which broke off from one of the plain ſort of *Houſeleek* Trees by Accident, and being planted in Lime-rubbiſh afterwards, became beautifully variegated; from which Plant there have been vaſt Numbers raiſed, and diſtributed into many curious Gardens, both at home and abroad. This is propagated in the ſame Manner as the former, and requires the ſame Management in *Winter:* But the Soil in which it is planted ſhould be one half freſh ſandy Soil, and the other half Lime-rubbiſh and Sea-ſand, equally mix'd, in which it will thrive much better than in a rich Soil: You muſt alſo be very careful not to give it too much Water in *Winter*, which will cauſe it to caſt its Leaves and decay. With this Management theſe Plants will grow to be eight or ten Feet high, and will produce beautiful Spikes of Flowers every Year, which are commonly in Beauty in *Winter*, and are thereby more valuable for coming at a Seaſon when few other Plants do flower. Sometimes theſe Plants will produce ripe Seeds, which, if permitted to fall upon the Earth of the Pots, will come up the *Summer* following, from whence a great Stock of the Plants may be produced; though as they do eaſily take Root from Cuttings, there will be no occaſion to propagate them any other Way.

The twelfth ſort ſeldom produces any ſide Branches, but grows up to one ſingle large Head, with very large Leaves. This is only propagated from Seeds; for when the Plants produce their Flowers, they always decay ſo ſoon as the Seed is ripe: Therefore the Seed ſhould be either ſown in Pots filled with light, ſandy Earth as ſoon as it is ripe, or permitted to ſhed upon the Pots where they grew; which muſt be ſheltered from the Froſt in *Winter*; and the *Spring* following the young Plants will come up in Plenty, when they ſhould be tranſplanted into Pots filled with freſh, light Earth, and expoſed in *Summer* with other exotick Plants, in ſome well-ſheltered Situation, where they may remain until *October*, when they ſhould be houſed with the foregoing Sorts, and managed in the ſame Manner as hath been directed for them. Theſe Plants will flower in four or five Years from Seed, provided they are well managed; after which (as was before ſaid) they uſually decay; therefore it is neceſſary to have a Succeſſion of young Plants, that there may be annually ſome to flower.

The thirteenth and fourteenth ſorts are of ſmaller Growth: Theſe do rarely riſe above ſix Inches high, but ſend forth a great Quantity of Heads from their Sides; which, if taken off and planted in freſh, light, ſandy Earth, will take Root, and make freſh Plants, which may be preſerved in Pots, and houſed in *Winter* with the other Sorts before-mentioned, and require to be treated in the ſame Way.

The fifteenth ſort grows to be ſhrubby, and may be propagated by planting the Cuttings, in the Manner directed for the Tree *Houſeleek*, and muſt alſo be houſed in *Winter*, and treated in the ſame Manner as hath been already directed for that ſort.

Theſe are all of them very ornamental Plants in the Green-houſe, and add greatly to the Variety, when placed amongſt other curious exotick Plants.

The laſt twenty ſorts of *Houſeleek* are very hardy Plants, which will thrive in the open Air in *England*, and may be eaſily propagated by Off-ſets or Branches, which will readily take Root. Thoſe Kinds which trail on the Ground (as many of theſe do) will puſh out Roots from their Branches, and thereby ſpread themſelves to a great Diſtance. But the thirtyſecond, thirtyfourth and thirtyfifth ſorts are annual Plants, which are only propagated by Seeds; but if their Seeds are permitted to ſcatter on the Ground, the Plants will come up in *Autumn*, and require no other Care, but to clear them from great Weeds, which, if permitted to grow amongſt them, would overthrow and deſtroy the Plants.

Theſe Plants are preſerved in the Gardens of ſome Perſons who are curious in Botany; but are very rarely admitted into other Gardens; tho' they may be very ornamental, when rightly diſpoſed. For there are no Plants ſo proper to plant on the Walls of Ruins, or other ruſtick Buildings, where they will thrive without any Trouble, and endure the greateſt Drought, and are never injured by Froſts. And as there is a great Variety of *Species*, which differ greatly from each other, not only in their Flowers, but alſo in the whole Face of the Plants; ſo they will afford an agreeable Variety, if they are properly diſpoſed. In planting of theſe Plants, there is no other Care required but to lay a little moiſt Earth on the Joints of the Walls or Buildings, where they are deſigned to grow, and therein to plant ſome of the Plants in ſmall Bunches, which will ſoon take Root, and in one Year's Time will ſpread to a conſiderable Diſtance. The beſt Seaſon for this Work is a little before *Michaelmas*, that the Plants may be rooted before the hard Froſt comes on. The annual Kinds will alſo grow in the ſame Manner, and will ſhed their Seeds and maintain themſelves without any Trouble, when they are once fixed in the Place. Theſe ſorts will moſt of them grow from the Joints of Walls, which are perpendicular, where ſcarce any other Plants will live; which renders them more valuable, eſpecially as they are ſo eaſily propagated.

The eighteenth, twentyfifth and twentyſixth ſorts produce long Branches, which hang down from the Walls where they grow; therefore ſhould be diſpoſed near the Edges of Buildings, or on the Tops of ruſtic Houſes, and near the Sides, where they will trail, and make a pretty Appearance.

The twentyeighth, twentyninth and thirtyſecond ſorts have the Appearance of the Stone-crop; theſe have ſhort Branches, and ſmall Leaves, producing their Flowers on the Tops of the Shoots, which are ſeldom above three or four Inches high, but ſpread and form into cloſe large Bunches; and where they ſcatter their Seeds, if there is but a ſmall Share of Earth, the Plants will come up, and multiply ſo faſt as to cover the Top of a Houſe in a few Years.

The ſixteenth, ſeventeenth, nineteenth, twentieth, twentyfirſt, twentyſecond, twentythird, twentyfourth, twentyſeventh, thirtieth, thirtyfirſt and thirtythird ſorts, grow in cloſe Heads, ſomewhat like the common *Houſeleek*, and are propagated by Off-ſets in the ſame Manner: Theſe may be diſpoſed on the Tops of Walls and Buildings, intermixed with the common ſorts of *Houſeleek*, where they will make a pretty Diverſity, being very different in their Appearance, and producing a great Variety in their Flowers.

SEED. The *Seed* of a Plant conſiſts of an Embryo, with its Coat or Cover. The Embryo, which contains the whole Plant in Miniature, and which is called the *Germ* or *Bud*, is rooted in the *Placenta* or *Cotyledon*, which makes the

Coat, or *Involucrum*, and ſerves the ſame Purpoſes as the *Secundines*, *i. e.* the *Chorion* and *Amnis* in Animals.

The *Placenta* or *Cotyledon* of a Plant is always double; and in the Middle and common Centre of the two is a Point or Speck, which is the Embryo or *Plantule*. This *Plantule* being acted on, and moved by the Warmth of the Sun and the Earth, begins to expand, and protrudes or ſhoots out its *Radicle* or Root both upward and downward. By this it abſorbs the nutritious Juice from the Earth, and ſo grows and increaſes; and the requiſite Heat continuing, the Growth continues.

Thus, *e. g.* a *Pea* or *Bean* being committed to the Ground, is firſt found to cleave into two Parts, which are, as it were, two Leaves or Lobes of the *Placenta*; and in the Fiſſure appears a Point, which ſhoots out a Root downwards, and a Bud upwards; the firſt ſpreading itſelf in the Soil to catch the Moiſture thereof; and the latter mounting into the Air, and becoming the Stem or Body of the new Plant.

It is very remarkable how the *Plumule* or future Stem ſhould always get uppermoſt, and the *Radicle* or Root be turned downwards, and this too perpendicularly to the Horizon: And not only this, but if, by any external Means, the Stem be diverted from this Perpendicular, and bent, for Inſtance, towards the Earth, inſtead of perſevering in that Direction, it makes an Angle or Elbow, and redreſſes itſelf.

The ſame is obſerved in Trees, &c. blown down, with their Roots, by the Wind; or in thoſe planted in Pots, upon turning the Pot on one Side.

Now the *Seed* from which a Plant ariſes, being the Plant itſelf in Miniature, 'tis eaſy to ſuppoſe, that if it be depoſited in the Ground with the *Plumule* perpendicularly upward, and the *Radicle* downward, the Diſpoſition ſhould be maintain'd in its future Growth.

But it is known, that *Seeds* ſown either of themſelves, or by the Help of Man, fall at Random, or among an infinite Number of Situations of the *Plumule*, &c. the perpendicular one upwards is but one; ſo that in all the reſt, 'tis neceſſary the Stem and Root do each make a Bend, to be able the one to emerge directly upwards, the other downwards. Now what Force is it that effects this Change, which is certainly an Action of Violence?

M. *Dodart*, who firſt took Notice of the *Phænomenon*, accounts for it by ſuppoſing the Fibres of the Stem of ſuch a Nature, as to contract and ſhorten by the Heat of the Sun, and lengthen by the Moiſture of the Earth; and, on the contrary, the Fibres of the Root to contract by the Moiſture of the Earth, and lengthen by the Heat of the Sun.

On this Principle, when the *Plantule* is inverted, and the Root a-top, the Fibres of the Root being unequally expos'd to the Moiſture, *viz.* the lower Parts more than the upper, the lower will contract; and this Contraction be promoted by the lengthening of the upper from the Action of the Sun. The Conſequence whereof will be, the Roots recoiling, inſinuating farther into the Earth, and getting beneath the Body of the Seed.

In a Word: The Earth draws the Root toward itſelf, and the Sun promotes its Deſcent: On the contrary, the Sun draws up the Plume, and the Earth, in ſome meaſure, ſends it towards the ſame.

M. *De la Hire* accounts for the ſame Perpendicularity, by only conceiving the Root to draw a coarſer and heavier Juice; and the Stem a finer and more volatile one. In the *Plantule* therefore we may conceive a Point of Separation, ſuch as, that all on one Side, *e. g.* the radial Part, is unfolded by the groſſer; and all on the other, by more ſubtile Juices.

If the *Plantule* then be inverted, and the Root a-top, as it ſtill imbibes the groſſer and heavier Juices, and the Stem the lighter; the Point of Separation being conceived as the fixed Point of a Lever, the Root muſt deſcend, and at the ſame Time that the volatile Juices imbibed by the Stem, tend to make it mount. Thus is the little Plant turned on its fixed Point of Separation, until it be perfectly erect.

The Plant thus erected, M. *Parent* accounts for the Stem's continuing to riſe in the virtual Direction, thus: The nutritious Juice being arrived at the Extremity of a riſing Stalk, and there fixing into a vegetable Subſtance, the Weight of the Atmoſphere muſt determine it to fix in a virtual Poſition; ſo that the Stalk will have acquired a new Part of Perpendicularity over the reſt; juſt as in a Candle, which held any how obliquely to the Horizon, the Flame will ſtill continue vertical by the Preſſure of the Air.

The new Drops of Juice that ſucceed, will follow the ſame Direction; and as all together form the Stem, that muſt of courſe be vertical, unleſs ſome particular Circumſtance intervene.

And, that whereas the Branches are likewiſe obſerved, as much as poſſible, to affect Perpendicularity; inſomuch, that tho' they be forced to ſhoot out of the Stem horizontally, yet in their Progreſs they erect themſelves: M. *Parent* ſolves this, from the vertical Tendency of the nutritious Juice up the Stem: For the Juice being received in this Direction into the new tender Bud, finds, at firſt, little Reſiſtance; and afterwards, as the Branch grows firmer, it furniſhes a longer Arm of a Lever to act by.

Mr. *Aſtrue* accounts for the perpendicular Aſcent of the Stems, and their redreſſing themſelves when bent, on theſe two Principles:

1. That the nutritious Juice ariſes from the Root to the Top in longitudinal Tubes, parallel to the Side of the Plant, which communicate either by themſelves, or by means of other horizontal Tubes, proceeding from the Circumference of the Plant, and terminated in the Pith.

2. That Fluids contained in Tubes, either parallel or oblique to the Horizon, gravitate on the lower Part of the Tubes, and not all on the upper.

From hence it eaſily follows, that in a Plant, poſited either obliquely or parallel to the Horizon, the nutritious Juice will act more on the lower Part of the Canals than the upper; and by that Means inſinuate more into the Canals communicating therewith, and be collected more copiouſly therein: Thus the Parts on the lower Side will act more on the lower Part, and will receive more Accretion(and be more nouriſhed than thoſe on the upper: The Conſequence whereof muſt be, that the Extremity of the Plant will be obliged to bend upward.

The ſame Principle brings the *Seed* into its due Situation at firſt. In a *Bean* planted upſide down, the Plume and Radicle are eaſily perceived with the naked Eye, to ſhoot at firſt directly for about an Inch; but thenceforth they begin to bend, the one downward and the other upward.

The two *Placentulæ* or *Cotyledones* of a *Seed*, are, as it were, a Caſe to this little tender *Plantule* or Point, covering it up, ſheltering it from Injuries, and feeding it from their own proper Subſtance; which the *Plantule* receives and draws to itſelf, by an infinite Number of little Filaments or Ramifications, called *Funes Umbilicales*, or Navel-ſtrings, which it ſends into the Body of the *Placenta*.

Now when the *Seed* is committed to the Earth, the *Placenta* ſtill adheres to the *Embryo* for ſome time, guards it from the Acceſs of noxious Colds, &c. and even prepares and purifies the cruder Juice the Plant is to receive from the Earth, by ſtraining it, &c. thro' its own Body.

This it continues to do, till the *Placentula* being a little inured to its new Element, and its Root tolerably fixed in the Ground, and fit to abſorb the Juice thereof; it then periſhes, and the Plant may be ſaid to be delivered; ſo that Nature obſerves the ſame Method in Plants, contained in Fruits, as in Animals in the Mother's Womb.

It is very ſurprizing, how many ſorts of *Seeds* will continue good for ſeveral Years, and retain their growing Faculty: whereas, many other ſorts will not grow when they are more than one Year old; which is, in a great meaſure, owing to their abounding more or leſs with Oil, and the Texture of their outward Covering. As for Example; the *Seeds* of *Cucumbers*, *Melons* and *Gourds*, which have thick, horny Coverings, do continue good eight ot ten Years; and *Radiſh*, *Turnip*, *Rape*, &c. with other oily *Seeds* (whoſe Coats, though they are not ſo hard and cloſe as the others) yet abounding with Oil, the *Seeds* will keep good three or four Years: Whereas the *Seeds* of *Parſley*, *Carrots*, *Parſnips*, and moſt other umbelliferous Plants, whoſe *Seeds* are, for the moſt part, of a warm Nature, do loſe their growing Faculty often in one Year, but do ſeldom remain good longer than two Years. But all Sorts of *Seeds* are preſerved beſt, if kept in the Pods or Huſks wherein they grew, So that whoever would ſend *Seeds* to a diſtant Country, ſhould always take Care they are full ripe before they are gathered, and that they are preſerved in their Pods or Huſks, and not ſhut up too cloſely from the Air, which is abſolutely neceſſary to maintain the Principle of Vegetation in the *Seed*, (tho' in a leſs Degree) as to nouriſh the Plant when germinated; as I found by trying the following Experiment, *viz.* Having ſaved a Parcel of freſh *Seeds* of ſeveral Kinds, as *Lettuce*, *Parſley*, *Onions*, &c. I took a Parcel of each Kind and put into Glaſs Phials; theſe I ſtopped down cloſe, and ſealed hermetically, then put them up in a Trunk: The other Parts of the ſame *Seeds* I put into Bags, and hung them up in a dry Room, where they remained a whole Year: and in the following *Spring* I took out a Part of each Parcel of *Seeds* from the Phials, as alſo from the Bags, and ſowed them at the ſame Time, and upon the ſame Bed, where they had an equal Advantage of Sun, Air, *&c.* The Conſequence of this was, almoſt all the *Seeds* which I took out of the Bags grew extremely well; but thoſe which were kept in the Phials did not one come up: After which I ſow'd the remaining Part of the *Seeds* in the Phials, but had not one ſingle Plant from the whole; whereas thoſe preſerved in the Bags grew very well both the ſecond and third Years. And this Experiment was afterwards try'd by one of my particular Friends, with whom the Effect was the ſame as with me. So that thoſe Perſons who ſend *Seeds* to a diſtant Country, ſhould never put them up in Glaſſes, as hath by ſome unſkilful Perſons been directed.

The Earth, which is the natural Nurſe to all *Seeds*, will preſerve them much longer than any other Body, provided they are buried ſo deep as to be beyond the Influence of *Sun* and *Showers*, whereby they are prevented from vegetating. I have known Seeds of ſeveral Plants remain buried three Feet deep above twenty Years, and when turn'd up to the Air have grown as well as freſh *Seeds*; and a particular Friend of mine, ſhew'd me a Spot of Ground which was cover'd with *Corn-ſallet*, the *Seeds* of which he aſſured me had been buried thirty-two Years in that Place; and when turn'd up again to the Air, were as productive as new *Seeds.*

A Method for raiſing ſuch Seeds *which have hard Coats or Shells ſurrounding them, and that have been judged very difficult, if not impoſſible, to be raiſed in* England.

In the Year 1724. I had a Parcel of freſh *Cocoa-Nuts* given me, which was brought over from *Barbadoes:* Part of theſe *Nuts* I diveſted of their outward Coat or Husk, and the other Part I left intire, as I receiv'd them.

Both theſe Parcels I planted in large Pots, fill'd with good freſh Earth, and plunged the Pots into Hot-beds made of Tanners-bark, giving them gentle and frequent Waterings, as the Earth in the Pots ſeem'd to require; but not one out of the whole Number had made any Attempt to ſhoot, as I could perceive; and upon taking them out of the Pots, I found they were rotten.

About four Months after I receiv'd another freſh Parcel of *Cocoa-Nuts* from *Barbadoes*, which I treated in another Manner: from Part of theſe I cut off the Outer-Coat or Husk, and the other Part I left intire, as before: but ſuppoſing it was owing to my planting the other Parcel in Pots, that they did not ſucceed, I made a freſh Hot-bed (with Horſe-dung) and cover'd it over with freſh Earth about eighteen Inches thick, in which I planted the Nuts; obſerving, as before, to ſupply it with convenient Moiſture, as alſo to keep the Hot-bed in an equal Temper of Heat which I was guided to do by a *Thermometer*, graduated for the Uſe of Hot-beds; but, with all my Care, I had no better Succeſs than before, not one of the Nuts making any Eſſay towards ſhooting.

The Year following, I had another Parcel of Cocoa-Nuts given me, which conſidering of my former ill Succeſs, I planted in a different manner, as follows:

Having a Hot-bed, which had been lately made with Tanners-bark, and which was fill'd with Pots of Exotick Plants, I removed two of the largeſt Pots, which were placed in the Middle of the Bed; and opening the Tanners-Bark under the Place where the two Pots ſtood, I placed the two Cocoa-Nuts therein, laying them Side-ways, to prevent the Moiſture (which might deſcend from the Pots) from entering the Hole at the Baſe of the Fruit, and thereby rot the ſeminal Plant upon its firſt germinating.

I then cover'd the Nuts over with the Bark two or three Inches thick, and placed the two Pots over them in their former Station.

In this Place I let the Nuts remain for ſix Weeks; when removing the two Pots, and uncovering the Nuts, I found them both ſhot from the Hole in the Baſe of the Fruit an Inch in Length, and from the other End of the Fruit were ſeveral Fibres emitted two or three Inches in Length.

Upon finding them in ſuch a Forwardneſs, I took them out of the Bark, and planted them in large Pots, fill'd with good freſh Earth; plunging the Pots down to the Rims in Tanners-bark, and covering the Surface of the Earth in the Pots half an Inch with the ſame; ſoon after which, the young Shoots were above two Inches long, and continued to thrive very well.

I communicated this Method to ſome of my Acquaintance, who have try'd it with the ſame Succeſs, and if the Nuts are freſh, ſcarce any of them miſcarry.

This led me to try, if the ſame Method would ſucceed as well with other hard-ſhell'd Exotick *Seeds*; which I could not, by any Method I had before try'd, get to grow; as the *Bonduc* or *Nickar-tree*, the *Abrus* or *Wild Liquorice*, the *Phaſeolus Braſilianus lobis villoſis pungentibus, maximus Hermanni* or *Horſe-eye Bean*, with ſeveral others; and I have found it both a ſure and expeditious Way to raiſe any Sort of hard-ſhell'd Fruits or Seeds.

For the Heat and Moiſture (which are abſolutely neceſſary to promote Vegetation) they here enjoy in an equal and regular Manner: The Tanners-bark (if rightly managed) keeping near an Equality of Heat for ſix Months, and the Water which deſcends from the Pots, when they are watered, is by the Bark detain'd from being too ſoon diſſipated; which cannot be obtain'd in a common Hot-bed, the Earth in ſuch being work'd away by the Water, and thereby leaving the *Seeds* often deſtitute of Moiſture.

Some of theſe *Seeds* I have had ſhoot in a Fortnight's time; which, I am inform'd, would not have ſo done in a Month, in their natural Soil and Climate.

I have alſo found this to be an excellent Method to reſtore *Orange* (or any other Exotick) Trees, which have ſuffer'd by a tedious Paſſage, in being too long out of the Ground; inſomuch that I recover'd two *Orange-trees*, which had been ten Months without either Earth or Water.

Having thus ſet down the general Definition of a Seed, and an Explanation of the Manner how Seeds vegetate; as alſo a Method how to raiſe ſuch exotick Seeds as have hard Covers, which will not vegetate in the ſame eaſy manner, as moſt other ſorts do; it may not be amiſs to add in this place a Table of the ſeveral Sorts of Seeds which are uſually ſown in the *Engliſh* Gardens, and to diſtinguiſh the Sorts which will keep good but a ſhort Time out of the Ground, from thoſe which, if well ſaved, and carefully preſerved, will grow, if kept ſome Years before they are ſown.

The firſt Claſs of Seeds which I ſhall enumerate, is of thoſe which ſhould be ſown in the *Autumn*, ſoon after they are ripe; otherwiſe many of them will not ſucceed, and others of them will often remain in the Ground a whole Seaſon, if they are kept out of the Ground till *Spring*, ſo that a full Year is thereby loſt:

Adonis *or* Flos Adonis, *ſee* Adonis.
Alexanders *or* Aliſſanders, *ſee* Smyrnium.
Anemony *or* Windflower, *ſee* Anemone.
Angelica.
Arſmart the Eaſtern Sort, *ſee* Perſicaria.
Aſh-keys, *ſee* Fraxinus.
Aſphodel *or* Kingſpear, *ſee* Aſphodelus.
Auricula.
Beech-maſt, *ſee* Fagus.
Biſhopſweed *ſee* Ammi.
Chriſtopher-herb, *ſee* Chriſtophoriana.
Ciceli, *ſee* Myrrhis.
Colchicum *or* Baſtard-ſaffron.
Cornſallet, *ſee* Valerianella.
Cornflag *ſee* Gladiolus.
Crocus.
Crown Imperial, *ſee* Corona Imperialis.
Fennel-grant, *ſee* Ferula.
Flower-de-luce, *ſee* Iris.
Fraxinella.
Fritillaria *or* Chequered Tulip.
Gentian, *ſee* Gentiana.
Ground-pine, *ſee* Champæpytis.
Hares-ear, *ſee* Bupleurum.
Hart-wort, *ſee* Bupleurum *and* Seſeli.
Hogs-fennel, *ſee* Peucedanum.
Hornbeam, *ſee* Carpinus.
Hyacinth, *ſee* Hyacinthus.
Juniper, *ſee* Juniperus.
Laſerwort, *ſee* Laſerpitium.
Lily, *ſee* Lilium.
Lily, Aſphodel, *ſee* Lilio-Aſphodelus.
Lily Hyacinth, *ſee* Lilio-Hyacinthus.
Lily Narciſſus, *ſee* Lilio-Narciſſus.
Lovage, *ſee* Liguſticum.
Mandrake, *ſee* Mandragora.
Maple tree, *ſee* Acer.
Maſterwort, *ſee* Imperatoria and Aſtrantia.
Mercury, *ſee* Mercurialis.
Moly.
Muſcari.
Narciſſus *or* Daffodil.
Oak *ſee* Quercus.
Oak of Jeruſalem, *ſee* Chenopodium.

Paſque-flower, *ſee* Pulſatillea.
Piony, *ſee* Pæonia.
Polyanthus, *ſee* Primula Veris.
Ranunculus *or* Crowfoot.
Samphire, *ſee* Crithmum.
Scurvy-graſs, *ſee* Cochlearia.
Seſeli *or* Sermountain, *ſee* Siler.
Snow-drop, *ſee* Narciſſo-lucoium.
Sowbread, *ſee* Cyclamen.
Spiderwort, *ſee* Phalangium.
Spignel, *ſee* Meum.
Star of Bethlehem, *ſee* Ornithogalum.
Staves-acre, *ſee* Delphinium.
Tulip, *ſee* Tulipa.
Turnſole, *ſee* Heliotropium.
Yew-tree, *ſee* Taxus.

In the next Claſs I ſhall enumerate thoſe Sorts of Seeds, which are beſt the firſt *Spring* after they are ſaved, many of which will not grow, if they are kept longer; ſo that whoever deals in Seeds, ſhould deſtroy the Seeds they have remaining after the Seaſon is over, and not ſell them to impoſe on their Dealers to the great Loſs of their Crops, nor keep them to mix with new Seeds, as is too often practiſed.

African Marygold, *ſee* Tagetes.
Agrimony, *ſee* Agrimonia.
Alkanet, *ſee* Anchuſa.
Amaranthoides *or* Globe-Amaranthus.
Aniſe, *ſee* Aniſum.
Aſparagus *or* Spearage.
Balſamina, *ſee* Balſamina.
Baſil, *ſee* Ocymum.
Baſtard-ſaffron, *ſee* Carthamus.
Bay-tree, *ſee* Laurus.
Bean, *ſee* Faba.
Beet, *ſee* Beta.
Blue-bottle, *ſee* Cyanus.
Borrage, *ſee* Borago.
Buckwheat, *ſee* Fagopyrum.
Bugloſs, *ſee* Bugloſſum.
Canterbury-bell, *ſee* Campanula.
Caraway, *ſee* Carum.
Carnation, *ſee* Caryophyllus.
Carrot, *ſee* Daucus.
Caterpillar, *ſee* Scorpioides.
Celery, *ſee* Apium.
Chervil, *ſee* Chærophyllum.
Cheſnut, *ſee* Caſtanea.
Chickling-pea, *ſee* Cicer.
Clary, *ſee* Horminum.
Columbine, *ſee* Aquilegia.
Coriander, *ſee* Coriandrum.
Cranesbill, *ſee* Geranium.
Creſs, *ſee* Naſturtium.
Cummin, *ſee* Cuminum.
Cypreſs, *ſee* Cupreſſus.
Dames-violet, *ſee* Heſperis.
Everlaſting-pea, *ſee* Lathyrus.
Fennel, *ſee* Fœniculum.
Fennel-flower, *ſee* Nigella.
Fenugreek, *ſee* Fœnum Græcum.
Finochia, *ſee* Fœniculum.
Firr, *ſee* Abies.
French-honeyſcukle, *ſee* Hedyſarum.
French-marygold, *ſee* Tagetes.
Goats-rue, *ſee* Galega.
Globe-thiſtle, *ſee* Echinopus.
Gromwel *or* Gray-mil, *ſee* Lithoſpermum.
Henbane, *ſee* Hyoſcyamus.
Hemp, *ſee* Cannabis.
Hollyhock, *ſee* Malva-roſea.
Hyſſop, *ſee* Hyſſopus.
Indian-pepper, *ſee* Capſicum.
Kidney-bean, *ſee* Phaſeolus.
Larch-tree, *ſee* Larix.
Larkſpur, *ſee* Delphinium.
Lavender, *ſee* Lavendula.
Laurel, *ſee* Lauroceraſus.
Leek, *ſee* Porrum.
Lentil, *ſee* Lens.
Love-apple, *ſee* Lycoperſicon.
Lupine, *ſee* Lupinus.
Lychnis *or* Catchfly.
Mad--apple, *ſee* Melongena.
Mallow the Venetian, *ſee* Ketmia.
Marjoram, *ſee* Majorana.
Marvel of Peru, *ſee* Jalapa.
Marygold, *ſee* Caltha.
Millet, *ſee* Milium.
Mullein, *ſee* Verbaſcum.
Moth-mullein, *ſee* Blattaria.
Navew, *ſee* Napus.
Oil-nut *or* Palma Chriſti, *ſee* Ricinus.
Roman-nettle, *ſee* Urtica.
Onion, *ſee* Cepa.
Orach, *ſee* Atriplex.
Origany, *ſee* Origanum.
Panic, *ſee* Panicum.
Parſley, *ſee* Apium.
Parſnip, *ſee* Paſtinaca.
Peaſe, *ſee* Piſum.
Pine, *ſee* Pinus.
Pink, *ſee* Caryophyllus.
Poppy, *ſee* Papaver.
Purſlain, *ſee* Portulaca.
Radiſh, *ſee* Raphanus.
Rape, *ſee* Napus.
Rue, *ſee* Ruta.
Savory, *ſee* Satureia.
Scabious, *ſee* Scabioſa.
Skirret, *ſee* Siſarum.
Snails, *ſee* Medica.
Snapdragon, *ſee* Antirrhinum.
Spinarch, *ſee* Spinarchia.
Stock Gilly-flower, *ſee* Leucoium.
Succory, *ſee* Cichorium.
Sun-flower, *ſee* Corona-ſolis.
Thyme, *ſee* Thymus.
Tobacco, *ſee* Nicotiana.
Trefoil, *ſee* Trifolium.
Turnep, *ſee* Rapa.
Venus Looking-glaſs, *ſee* Campanula.
Venus Navelwort, *ſee* Omphalodes.
Vetch, *ſee* Vicia.
Woad, *ſee* Iſatis.
Walflower, *ſee* Leucoium.

The next Claſs of Seeds are ſuch as may be kept two Years, and will not be the worſe, provided they are well ſaved. Tho' theſe are equally good for Uſe the firſt Year.

Amaranthus *or* Flower-gentle.
Citrul *or* Water-melon, *ſee* Anguria.
Cabbage, *ſee* Braſſica.
Clover, *ſee* Trifolium.
Colliflower, *ſee* Braſſica.
Convolvulus *or* Bindweed.
Endive, *ſee* Endivia.
Flax, *ſee* Linum.
Indian Flowering-reed, *ſee* Cannacorus.
La-lucern, *ſee* Medica.
Lavender, *ſee* Lavendula.
Lettuce, *ſee* Lactuca.
Melilot, *ſee* Melilotus.
Muſtard, *ſee* Sinapi.
Sorrel, *ſee* Acetoſa.

The third Claſs of Seeds are ſuch as may be kept three Years or more, and will grow very well afterward, provided they are well ſaved; and ſome of the Sorts are generally preferred for being three Years old, particularly the *Cucumber* and *Melon* Seeds; becauſe when the Seeds are new, the Plants grow too vigorous, and produce a ſmall Quantity of Fruit: but it is not proper to keep theſe longer than three Years, notwithſtanding they will grow at eight or nine Years old; becauſe when the Seeds are old, the Plants will be weak, and the Fruit which they produce will be ſmall:

Amaranthus *or* Flower-gentle.
Cabbage, *ſee* Braſſica.
Cedar of Libanus, *ſee* Cedrus, *if kept in the Cones.*
Cucumber, *ſee* Cucumis.
Gourd, *ſee* Cucurbita.
Lettuce, *ſee* Lactuca.
Melon, *ſee* Melo.
Pumpio, *ſee* Pepo.
Savoy, *ſee* Braſſica.
Semnel *or* Squaſh, *ſee* Melopepo.
Water Melon, *ſee* Anguria.

The following is a Liſt of ſuch Seeds, as do frequently remain in the Earth a whole Year, eſpecially if they are ſown in the *Spring* of the Year; ſo that whenever the Plants do not come up the firſt Year, the Ground ſhould remain undiſturbed till the following *Spring*, (but muſt be kept clear from Weeds) when the Plants will come up:

Adonis *or* Flos Adonis.
Alaternus.
Alexanders, *ſee* Smyrnium.
Angelica, *ſee* Valerianella.
Corn-ſallet Fennel, *ſee* Fœniculum.
Fraxinella *or* white Dittany.
Grom-well *or* Gray-mill, *ſee* Lithoſpermum.
Hareſear, *ſee* Bupleurum.
Hartwort, *ſee* Bupleurum.
Hawthorn, *ſee* Meſpilus.
Hogs-fennel, *ſee* Peucedanum.
Holly, *ſee* Aquifolium.
Juniper, *ſee* Juniperus.
Laſerwort, *ſee* Laſerpitium.
Lovage, *ſei* Liguſticum.
Maple *ſee* Acer.
Maſterwort, *ſee* Aſtrantia.
Mercury, *ſee* Mercurialis.
Moly.
Piony, *ſee* Pœonia.
Seſeli *or* Sermountain, *ſee* Siler.
Spignel, *ſee* Meum.
Staves-acre, *ſee* Delphinium.
Turnſole, *ſee* Heliotropium.
Yew, *ſee* Taxus.

If the Seeds mentioned in this Liſt are ſown after they are ripe, many of the Sorts will come up the following *Spring*; but whenever they fail ſo to do, there will be no Danger of their growing the following Year, provided the Seeds were good; therefore People ſhould not deſpair of them the firſt Year. Moſt of the *Umbelliferous* Plants have this Property of remaining in the Ground ſeveral Months, and ſometimes a whole Year, before the Plants appear; therefore they ſhould be managed accordingly, by ſowing their Seeds on a Border, which can be ſuffered to remain undiſturbed till the Plants come up. There are ſome particular ſorts of Seeds, which I have known remain in the Ground eighteen Months, and ſometimes two Years; after which Time the Plants have come up very well; of theſe Sorts are the *Morina*, *Tribulus terreſtris*, *Staveſacre*, *Mercury*, and ſome others; but as they do not conſtantly remain ſo long in the Ground, ſo there can be no Certainty of the Time when the Plants will appear.

The Rules here laid down, concerning the Length of Time which Seeds may be kept out of the Ground, and prove good, will in general be found true, being drawn up from ſeveral Years Experience, having taken Notes every Year from the Times of ſowing great Varieties of Seeds, to the Appearance of the Plants above Ground. And in this, I have obſerved ſuch Oddneſs in the Growth of Seeds, as is not to be accounted for; as that of ſowing Seeds of the ſame Plant for two or three Years ſucceſſively, and not having had one Plant ariſe; and the fourth Year from the remaining Part of the Seeds, I have had ſome Plants come up, notwithſtanding the Age of the Seeds. At other times it has happened, that ſome Seeds have grown the ſame *Spring* they were ſown, and a great Part of them have remained in the Ground till the following *Autumn*, when the Plants have come up; ſo that there have been two different Crops, from the ſame ſowing.

I have alſo tried many Experiments in keeping of Seeds, and find the beſt Method to preſerve them good, is to keep them in moderate Temperature of Warmth, where they may not ſuffer from any Inclemencies in the outward Air, nor have too much Warmth, which will exhale the Moiſture too freely, and cauſe the Seeds to decay ſooner than they otherwiſe would do. This is well known to moſt People who cultivate *Melons*; who, when their Seeds are new, which would occaſion the Plants being too vigorous, and therefore not ſo fruitful, put them into the inner Pocket of their Breeches, which are in conſtant Wear, where they keep them for ſix Weeks or two Months before they ſow them; which will weaken the Seeds, as much as two Years longer keeping in the ordinary Way.

All Sorts of Seeds will keep much longer in their Pods, or outer Coverings, where they can be thus preſerved; becauſe the Covering not only preſerves them from the Injuries of the outward Air, but if the Seeds are not ſeparated from them, they ſupply them with Nouriſhment, and thereby keep them plump and fair. But the Seeds of all ſoft Fruits, ſuch as *Cucumbers*, *Melons*, &c. muſt be cleanſed from the Fruit and Mucilage which ſurrounds them; otherwiſe the rotting of theſe Parts will corrupt and decay the Seeds in a ſhort time.

When Seeds are gathered, it ſhould always be done in dry Weather, when there is no Moiſture upon them; and then they ſhould be hung up in Bags, (eſpecially thoſe which Vermin eat) in a dry Room; in which Situation they will keep good, longer than if they were more cloſely ſhut up, and Air excluded from them.

There are but few People ſo curious as they ſhould be, in ſaving of their Seeds: ſome, for want of Judgment, do not diſtinguiſh the beſt Plants of their Kinds, to let grow for Seeds; and others out of Covetouſneſs, to ſave a great Quantity of Seeds, frequently let a whole Spot of Ground, filled with any particular Sort of Plants, run up to Seed; ſo that the good and bad Plants are ſaved indifferently, which is the Occaſion of the general Complaint of the Badneſs of the Seeds which are commonly vended, and is what the Dealers in Seeds ſhould endeavour to remedy.

In the Tables here ſubjoined, I have given the common *Engliſh* Names of the Seeds, oppoſite to which I have added the *Latin* Names, that the Reader may with Eaſe turn to the ſeveral Articles in the Dictionary; where each Sort is particularly treated of, and Directions are given for their Management.

SEGMENT-LEAVES, are Leaves of Plants divided or cut into many Shreds.

A SEMINARY, is a Seed-plot, which is adapted or ſet apart for the ſowing of Seeds. Theſe are of different Natures and Magnitudes, according to the ſeveral Plants intended to be raiſed therein. If it be intended to raiſe Timber or Fruit-Trees, it muſt be proportionably large to the Quantity of Trees deſigned, and the Soil ſhould be carefully adapted to the various Sorts of Trees. Without ſuch a Place as this, every Gentleman is obliged to buy, at every Turn, whatever Trees he may want to repair the Loſſes he may ſuſtain in his Orchard, Wilderneſs, or larger Plantations; ſo that the Neceſſity of ſuch a Spot of Ground will eaſily be perceiv'd by every one. But as I have already given Directions for the preparing the Soil, and ſowing the Seeds in ſuch a *Seminary*, under the Article of *Nurſery*, I ſhall not repeat it in this Place, but refer the Reader to that Article.

It is alſo as neceſſary for the Support of a curious Flower-Garden, to have a Spot of Ground ſet apart for the ſowing of all Sorts of Seeds of choice Flowers, in order to obtain new Varieties; which is the only Method to have a fine Collection of valuable Flowers; as alſo for the ſowing of all Sorts of biennial Plants, to ſucceed thoſe which decay in the Flower-Garden; ſo that the Borders may be annually repleniſh'd, which without ſuch a *Seminary* could not be ſo well done.

This *Seminary* ſhould be ſituated at ſome Diſtance from the Houſe, and be intirely incloſed either with a Hedge, Wall, or Pale, and kept under Lock and Key, that all Vermin may be kept out, and that it may not be expoſed to all Comers and Goers, who, many times, do Miſchief before they are aware of it. As to the Situation, Soil, and Manner of preparing the Ground, it has been already mention'd under the Article of *Nurſery*, and the particular Account of raiſing each Sort of Plant, being directed under their proper Heads, it would be needleſs to repeat it here.

SEMIFISTULAR FLOWERS, are ſuch whoſe upper Part reſembles a Pipe, cut off obliquely, as in *Ariſtolochy* or *Birth-wort*.

SEMINAL LEAVES, are two plain, ſoft, and undivided *Leaves*, that firſt ſhoot forth from the greateſt Part of all ſown Seeds; which *Leaves* are very different from thoſe of the ſucceeding Plant in Size, Figure, Surface, and Poſition.

SEMINIFEROUS, Bearing or producing Seed.

SENECIO, [ſo call'd of *Seneſcere*, Lat. *to wax old*, becauſe in a hot Climate or Weather it ſoon flouriſhes, and grows old, and the Seed afterwards repreſents the Heads of Old Men. It is alſo call'd *Erigeron*, of ἦρ, *in the Spring*, and γεράω, to *wax old*; q. d. the *Old Man of the Spring*; becauſe it flouriſhes in *Winter*, and ſo becomes old in the *Spring*. It is alſo call'd *Herba Pappa*, becauſe its Seeds are very downy] Groundſel.

The *Characters* are;

It hath a floſculus Flower, conſiſting of many Florets, divided into ſeveral Segments, ſitting on the Embryo, contain'd in an

Empalement, conſiſting of one Leaf, and divided into many Parts, afterwards becoming of a conical Figure: the Embryo afterwards becomes a Seed, furniſh'd with Down; at which time, the Empalement is reflex'd, to make way for the Seeds to eſcape.

The *Species* are;

1. Senecio *minor vulgaris. C. B. P.* Common Groundſel.

2. Senecio *Africanus arboreſcens, folio ſerrato. Boerh. Ind.* African Tree-like Groundſel, with a ſerrated Leaf.

3. Senecio *Virginianus arboreſcens, atriplicis folio. Par. Bat.* Virginian Groundſel-Tree, with an Orach Leaf.

The firſt Sort here mention'd is one of the moſt common Weeds upon Dunghills, old Walls, and Gardens, that we have in *England*; ſo that inſtead of cultivating it, it requires ſome Pains to deſtroy it in Gardens: for if it be ſuffer'd to ſeed in a Garden, (which it ſoon will do, if permitted to ſtand) it will be very difficult to extirpate it. This is ſometimes uſed in Medicine; but its chief Uſe in *England* is to feed Birds.

The ſecond Sort grows to a Shrub of ſeven or eight Feet high, and produces its Flowers, in *Summer* and *Autumn*, at the Extremity of the Branches, in Bunches; which, tho' of no great Beauty, yet ſerves to add to the Variety of Exotick Plants in the Green-houſe. This Plant may be propagated by planting the Cuttings, during any of the *Summer* Months, in a Bed of freſh rich Earth, obſerving to water and ſhade them until they have taken Root; after which they will require no farther Care, but to keep them clear from Weeds until *Auguſt*, when they ſhould be taken up carefully, and planted into Pots fill'd with light rich Earth, and placed in a ſhady Situation until they have taken Root; after which they may be removed to a more open Situation, where they may remain till the latter End of *October*; when they ſhould be removed into the Green-houſe, placing them in the coldeſt Part thereof; for they only require to be ſhelter'd from ſevere Froſt, and muſt have as much free Air as poſſible in mild Weather; and be after refreſh'd with Water: in *Summer* they may be expoſed with *Myrtles*, *Oleanders*, and other hardy Exotick Plants, where they will add to the Variety.

The third Sort doth grow to be a large woody Shrub, about ten or twelve Feet high, but is hardly to be train'd up into a regular Figure; for the Branches are produced ſo irregularly, that it makes but an indifferent Figure in a Garden; but it being a hardy Shrub, it is often preſerved by ſuch as are curious in collecting the various Sorts of hardy Plants.

This may be propagated by planting Cuttings, taken from the tender Wood, in the *Spring* of the Year, obſerving to water and ſhade them until they have taken Root; after which they muſt be carefully kept clear from Weeds, which is all the Management they will require until the ſucceeding *Spring*, when they ſhould be tranſplanted either into the Places where they are deſign'd to grow, or into a Nurſery, where they may be train'd up another Seaſon; tho' it is the beſt Way to plant them where they are to remain, when they are taken from the Bed where they were raiſed, becauſe theſe Plants are with Danger removed, when they are grown very woody.

The beſt Time to remove them is in the Beginning of *April*, juſt before they ſhoot; and they ſhould be placed in a light Soil, and a warm Situation, where they will endure the Cold of our ordinary *Winters* without any Shelter; but in very ſharp *Winters* they are ſometimes deſtroy'd. This Shrub produces its Flowers in *October*, which, although not very beautiful, yet are eſteem'd by ſome, for their coming ſo late in the Seaſon.

SENNA, [ſo call'd of *Sana*, Lat. *Healthy*, becauſe its Leaves reſtore Health.]

The *Characters* are;

The Flower for the moſt part conſiſts of five Leaves, which are placed orbicularly, and do expand in form of a Roſe; the Pointal afterwards becomes a plain, incurved, bivalve Pod, which is full of Seeds, each being ſeparated by a double thin Membrane.

The *Species* are;

1. Senna *Italica, foliis obtuſis. C. B. P.* Italian *Senna*, with blunt-pointed Leaves.

2. Senna *Americana, Liguſtri folio. Plum.* American *Senna*, with a Privet Leaf.

3. Senna *Alexandrina, ſive foliis acutis. C. B. P.* Alexandrian *Senna*, with ſharp-pointed Leaves.

The two firſt *Species* are preſerv'd in ſeveral curious Gardens in *England*; but the third Sort, which is that uſed in Medicine, is at preſent very rare in this Country.

Theſe Plants may be propagated by ſowing their Seeds upon a Hot-bed early in the *Spring*; and when the Plants are come up, they ſhould be tranſplanted into ſmall Pots, fill'd with light freſh Earth, and plunged into a new Hot-bed, obſerving to water them and ſhade them until they have taken Root; after which they ſhould have Air admitted to them, by raiſing the Glaſſes in Proportion to the Warmth of the Seaſon, and the Bed in which they are placed; you muſt alſo obſerve to refreſh them with Water from time to time, as the Earth in the Pots ſhall require; and when the Roots of the Plants have fill'd the Pots, they ſhould be ſhifted into other Pots a Size larger, obſerving to take off the Roots which are matted round the Outſide of the Ball of Earth next the Pot, and then fill up the Pots with the ſame freſh Earth, and plunge them into the Hot-bed again, giving them Air and Water in Proportion to the Warmth of the Seaſon, and the Bed in which they are placed; in this Manner they muſt be treated until *Autumn*, when they muſt be removed into the Stove, and plunged into the Bark-bed, where, during the *Winter* Seaſon, they muſt be carefully preſerved, refreſhing them with Water every three or four Days, according as the Earth in the Pots dries. This Stove ſhould be kept above temperate Heat in *Winter*, otherwiſe the Plants will not live therein. The *Summer* following, the two firſt *Species* will flower, and produce Seed; but the third Sort doth ſeldom flower ſo young; however, in a few Years, if it be rightly managed, it will produce both Flowers and Seeds.

SENNA-SPURIA, Baſtard-Senna.

Doctor *Tournefort*, in his Method, makes the Character of *Senna* to have a flat Pod, for the moſt part incurved; and the Character of *Caſſia* to have ſwelling Pods, and the Seeds ſurrounded with Pulp; ſo that there are many Plants, which agree in the Flower, and outward Appearance, with the *Caſſia* and *Senna*, that by this Method are removed from them; therefore Dr. *Herman* has given the Name of *Senna-Spuria* to theſe Plants.

The *Characters* of which are;

It hath an irregular roſaceous Flower, (which ſomewhat reſembles a Butterfly-Flower) whoſe Pointal afterwards becomes a Pod, having for the moſt part two Rows of Seeds.

The *Species* are;

1. Senna-Spuria *Americana minor herbacea, plerumque hexaphylla, folio obtuſo. Houſt.* Small *American* herbaceous Baſtard-Senna, having for the moſt part ſix obtuſe *Pinnæ*, or Wings, on each Leaf.

2. Senna-Spuria *Americana herbacea, ore gravi, orobi Pannonici foliis mucronatis & hirſutis. Houſt.* Stinking herbaceous *American* Baſtard-Senna, with Leaves like the *Portugal* Bitter-Vetch, which are pointed and hairy.

3. Senna-Spuria *Americana fruteſcens, foliis mucronatis glabris minoribus, ſiliquis teretibus, duplici ſeminum ordine fœtis. Houſt.* Shrubby *American* Baſtard-Senna, with the leaſt ſmooth pointed Leaves, and taper Pods, containing two Rows of Seeds.

4. Senna-Spuria *Americana, plerumque hexaphylla, flore magno, ſiliquâ pentagonâ alatâ. Houſt.* *American* Baſtard-Senna, for the moſt part having ſix Wings to the Leaf, a large Flower, and a five-cornered winged Pod.

5. Senna-Spuria *Americana herbacea, orobi Pannonici foliis rotundioribus, flore parvo, ſiliquis erectis. Houſt.* *American* herbaceous Baſtard-Senna, with rounder *Portugal* bitter-vetch Leaves, a ſmall Flower, and an erect Pod.

6. Senna-Spuria *Americana arborea villoſa, foliis latis mucronatis, ſiliquis articulatis. Houſt.* Hoary *American* tree-like Baſtard-Senna, with broad pointed Leaves, and jointed Pods.

7. Senna-Spuria *Americana arborea, ſiliquis compreſſis anguſtis longiſſimis pendulis. Houſt.* *American* tree-like Baſtard-Senna, with narrow flat Pods, which are very long, and hang downward.

8. Senna-Spuria *Americana tetraphylla herbacea procumbens, ſiliquis hirſutis. Houſt.* *American* four-leav'd herbaceous trailing Baſtard-Senna, with hairy Pods.

9. Senna-Spuria *Americana, ſiliquâ multiplici, foliis herbæ mimoſæ. Houſt.* *American* Baſtard-Senna with many Pods, and Leaves like thoſe of the Senſitive Plant.

10. Senna-Spuria *Americana fruteſcens, mimoſæ foliis, flore parvo, ſiliquis hirſutis, breviſſimis pediculis inſidentibus. Houſt.* Shrubby *American* Baſtard-Senna, with Leaves like

thoſe of the Senſitive Plant, a ſmall Flower, and hairy Pods growing on ſhort Footſtalks.

11. Senna-Spuria *Americana fruteſcens & procumbens, flore maximo, ſiliquis glabris. Houſt.* Shrubby and trailing *American* Baſtard-Senna, with a large Flower, and ſmooth Pods.

12. Senna-Spuria *Americana minima procumbens, foliorum pinnis ſubrotundis, glabra. Houſt.* The leaſt trailing *American* Baſtard-Senna, with roundiſh Wings to the Leaves, which are ſmooth.

13. Senna-Spuria *Americana, foliis herbæ mimoſæ, ſiliquâ ſingulari, floribus pediculis longioribus inſiſtentibus. Sloan. Hiſt.* *American* Baſtard-Senna, with Leaves like thoſe of the Senſitive Plant, and a ſingle Pod ſuſtained by a long Footſtalk.

14. Senna-Spuria *fruteſcens, foliorum pinnis latioribus, caulibus piloſis, ſiliquis longiſſimis pediculis inſidentibus. Houſt.* Shrubby Baſtard-Senna, with broader Wings to the Leaves, a hairy Stalk, and Pods growing on long Footſtalks.

15. Senna-Spuria *minima procumbens, foliorum pinnis ſubrotundis, caule pubeſcente. Houſt.* The leaſt trailing Baſtard-Senna, with roundiſh winged Leaves, and a downy Stalk.

Theſe Plants are all of them Natives of the warm Parts of *America*: ſome of them were diſcovered in *Jamaica*, and the others were found at *Campechy*, and *La Vera Cruz*, by the late Dr. *William Houſton*, who ſent their Seeds to *England*, where many of the Plants are now growing.

They are propagated by Seeds, which ſhould be ſown on a Hot-bed early in the *Spring*; and when the Plants come up, they muſt be frequently watered; and if the Nights ſhould prove cold, the Glaſſes of the Hot-bed ſhould be covered with Mats every Evening, to keep the Bed in a moderate Temperature of Heat: but in the Day-time, when the Sun ſhines warm, the Glaſſes ſhould be raiſed with Stones, to admit freſh Air to the Plants, which will prevent their drawing up weak. When the Plants are about two Inches high, they ſhould be carefully tranſplanted, each into a ſeparate ſmall Pot, filled with light freſh Earth, and plunged into a moderate Hot-bed of Tanners-bark, being careful to ſhade them from the Sun, until they have taken new Root; after which Time they muſt have freſh Air admitted to them every Day, in proportion to the Warmth of the Seaſon; and ſo long as the Nights continue cold, the Glaſſes muſt be every Evening covered with Mats, ſoon after the Sun is gone off from the Bed. Theſe Plants do moſt of them grow in moiſt Places; ſo they ſhould be frequently refreſhed with Water, and in *Summer* they muſt have it given to them plentifully, otherwiſe they will not thrive.

In about five or ſix Weeks after planting, if the Plants have thriven well, they will have filled theſe ſmall Pots with their Roots; therefore they ſhould then be ſhaken out of the ſmall Pots, and their Roots trimmed, and then planted into larger Pots, and plunged again into the Hot-bed. Such of them as may have grown too tall to remain under the Frames, ſhould be plunged into the Tan-bed in the Stove; but the others may be plunged into the former Hot-bed again, after having ſtirr'd up the Tan. As theſe Plants obtain Strength, ſo they ſhould have a larger Share of freſh Air admitted to them; otherwiſe they will draw up very weak, and become very tender, and very ſubject to be infeſted by Inſects, which will render them unſightly, and prevent their Flowering.

The firſt, ſecond, fourth, fifth, eighth, ninth, twelfth, thirteenth and fifteenth Sorts, frequently flower the firſt Seaſon; but if they do not flower pretty early in *Auguſt*, they will not produce ripe Seeds, unleſs they are placed in a warm Stove, and plunged into the Bark-bed; ſo that where this Conveniency is wanting, they muſt be raiſed early in the *Spring*, and brought as forward as poſſible in the *Spring* Seaſon, otherwiſe good Seeds cannot be obtained in this Country.

The third, ſixth, ſeventh, tenth, eleventh and fourteenth Sorts, are abiding Plants, which grow ſhrubby; therefore ſhould be inured to bear a large Share of Air, that they may become hardy in *Autumn*; for theſe may be placed in the dry Stove in *Winter*, where, if they are kept moderately warm, they will thrive and produce their Flowers in plenty. In the *Summer* Seaſon, theſe Plants may be placed abroad in a warm Situation, where they are ſecured from ſtrong Winds; but they muſt be removed into the Stove in *September*, when the Nights begin to grow cold; otherwiſe they will loſe their Leaves, and become very unſightly. Moſt of theſe Plants produce their Flowers in *Winter*, which renders them valuable, becauſe in that Seaſon there are not many Plants which make a better Appearance. The ſeventh Sort will grow to the Height of twelve or fourteen Feet, and will abide many Years. This conſtantly produces Flowers in the middle of *Winter*; which being large, and produced in Cluſters at the Extremity of the Branches, make a fine Appearance at that Seaſon.

SENNA THE BLADDER: *vide* Colutea.

SENNA THE SCORPION: *vide* Emerus.

SENSIBLE PLANT: *vide* Mimoſa.

SEPTEMBER.

Work to be done in the Kitchen Garden.

The Beginning of this Month you muſt prick out your Cauliflower Plants which were ſown the laſt Month, placing them either upon old Cucumber or Melon Beds; for if they are put upon Beds without any Dung under them, the Worms will draw them out of the Ground; but if the Seaſon proves cold, and your Plants are backward, it will be proper to make ſome new Beds with warm Dung, which will bring them forward. The Diſtance which theſe Plants ſhould be allow'd in theſe Beds, is three Inches, Row from Row, and about two Inches aſunder in the Rows, which will be ſufficient Room for them to grow till *October*, when they muſt be tranſplanted again into their *Winter* Beds.

You may now make Muſhroom Beds, in doing of which, you muſt obſerve to make choice of ſuch Dung as hath lain about three Weeks or a Month on a Heap, whereby its great Heat is loſt; and let your Knobs of Spawn be laid to dry in a ſhady Place, three or four Days before you put them into the Bed.

Hough and clean Turnips, and the Spinach, which was ſown the laſt Month, from Weeds, cutting out the Plants where they are too cloſe, obſerving, if poſſible, to do this in dry Weather, otherwiſe the Weeds will take Root again, and be very troubleſome. You ſhould alſo weed the Beds of Onions, Carrots, Cabbage Plants, and Coleworts, which were ſown the laſt Month; for if the Weeds are permitted to grow, they will ſoon over-top the Plants, and ſpoil them.

Earth up your Celery as it advances in Height, obſerving always to do it in dry Weather; and be careful not to earth it above the Hearts of the Plants, becauſe that would prevent its growing tall, and many times occaſion its rotting.

The Beginning of this Month you may ſafely tranſplant moſt Sorts of perennial Aromatick Plants, as Roſemary, Lavender, Stœchas, *&c.* which will take Root again before the Froſt comes on to prevent them.

Continue to ſow ſmall Sallet-herbs, ſuch as Radiſh, Turnip, Creſſes, Muſtard, Chervil, *&c.* but as the Cold increaſes, they ſhould have a warmer Situation, otherwiſe the Morning Froſts will looſen the Ground, and cauſe the Herbs to turn their Roots out, whereby they will be deſtroy'd.

Draw the Earth up about Chardoons, in order to blanch them; but this muſt be done in dry Weather.

Gather all ſorts of Seeds as they ripen, and ſpread them to dry them upon Mats or Cloths; and then beat them out of their Huſks, and put them up in a dry Place until the Seaſons for ſowing of them.

In moiſt Weather you may tranſplant your Colewort Plants, which were ſown in *July*, into the Places where they are to remain till *Spring*: and you ſhould alſo tranſplant your Cabbage Plants which were ſown the Beginning of *Auguſt*, that they may acquire Strength before they are planted out for good.

Tranſplant ſome of your late ſown Endive on Borders under warm Wall, Pales, or Hedges, to ſtand till *February* before it is blanched; and in dry Weather tie up ſuch Endive as is full grown, to blanch it for Uſe.

If the Seaſon ſhould prove dry, you ſhould water your late Crop of Cauliflowers, which are to come the next Month, otherwiſe their Heads will be very ſmall, eſpecially if the Ground be dry.

Continue to keep all your late Crops clear from Weeds; for if they are not well clean'd before the great Rains of *Autumn* fall, it will be difficult to deſtroy the Weeds afterward.

Toward the latter End of this Month you ſhould tranſplant Lettuces of ſeveral ſorts upon warm Borders, where they may remain to cabbage early in the *Spring*; but you may plant them pretty cloſe together at this Seaſon, becauſe if they live thro' the *Winter*, Part of them may be tranſplanted out in the *Spring*, into an open Spot of Ground, where they will grow larger than thoſe left in the Borders, but will not be fit for Uſe ſo ſoon by a Fortnight or three Weeks, which is an Advantage, in having them continue ſo much longer, to ſupply the Table.

You may now cut down the Haulm of Aſparagus, which is beginning to wither, and clear the Weeds off from the Beds into the Alleys, where they ſhould be buried, and the Earth of the Alleys ſhould be laid upon the Beds, to new mould them; and where the Beds want dunging, there ſhould be ſome very rotten Dung taken out of old Cucumber and Melon Beds, and laid upon the Aſparagus Beds, after the Weeds are houghed off, and then covered over with the Earth from the Alleys.

If there ſhould happen much Rain at this Seaſon, your Cauliflower Plants muſt be protected therefrom, otherwiſe it will rot their tender Stems, and decay them in a ſhort Time.

Moſt of your *Summer* Crops being entirely cleared from off the Ground, you ſhould in dry Weather hough and clear the Ground from Weeds, which will preſerve the Ground neat until you ſhall prepare it for freſh Crops.

At the End of this Month you may plant ſome Beans, and ſow ſome early Peas, in warm Borders, where, if they abide the *Winter*, they will produce their Crops early the ſucceeding *Spring*.

Products of the KITCHEN-GARDEN.

Cabbages, Carrots, Artichokes, Parſnips, Potatoes, Shallots, Onions, Leeks, Garlick, Chardoons, Celery, Endive, Cabbage-lettuce of ſeveral Sorts, Scorzonera, Salſafy, Muſhrooms, Cucumbers for pickling, Melons, Kidney-beans, Rouncival Peas, Marrow-fat Peas, Garden Beans planted late, Beets, Turnips, Radiſhes, Sprouts, and all Sorts of young Sallet-herbs.

Work to be done in the FRUIT-GARDEN.

Your Fruits ſhould now be gathered as they ripen; for thoſe which are in Eating this Month ſeldom continue long good; but toward the End of the Month moſt Sorts of *Winter* Fruit will be fit to gather; but you ſhould always ſuffer them to remain as long upon the Trees as the Weather will permit; for when they are gathered too early, their Skins will ſhrivel, and the Fruit will not keep well; and there will be no Danger of their ſuffering upon the Trees until the Mornings begin to be froſty, when you muſt not let the Fruit hang longer, becauſe if the Froſt ſhould pinch their Skins, it would greatly injure them. You muſt always obſerve to gather your Fruit when the Trees are perfectly dry, otherwiſe your Fruit will not keep.

The latter End of this Month you may ſafely tranſplant moſt Sorts of *Summer* Fruit-trees, altho' their Leaves have not yet fallen, ſuch as Cherries, Nectarines, Peaches, Summer Pears and Apples: You may alſo begin to prune Cherries, Peaches, Nectarines, Grapes and Figs, at the End of the Month, eſpecially if their Leaves begin to decay; and by performing this Work early, the Wounds will heal before the cold Weather comes on, and the Garden will be clear from the Litter which is occaſioned by the Leaves falling.

The Grapes of the Vineyard, which are now almoſt ripe, muſt be guarded from Birds, which will make great Havock of them, where they are ſuffered to feed upon them without Moleſtation; and where the Birds have peck'd any of the Grapes, the Flies and Waſps will immediately attack them, and eat them up.

Tranſplant Strawberries, Raſpberries, Gooſberries, and Currants, toward the End of this Month, if the Weather proves moiſt, otherwiſe it will be better to defer it until the next Month.

Your Fruits againſt the Wall of your Forcing-frame muſt now be pruned and trained cloſe to the Wall or Eſpalier, that their Buds may be preparing before the Seaſon for applying the Heat.

Fruits in prime, or yet laſting.

Peaches; The Nivette, Portugal Peach, Purple Alberge, Old Newington, Teton de Venus, Pavy Royal, Admirable, Monſtrous Pavy of Pompone, Catharine, Rumbullion, Malacoton.

Plums; White Pear Plum, Bonum Magnum, Imperatrice, Damſons, and Bullace.

Pears; Poire de Prince, Autumn Bergamot, Swiſs Bergamot, Brute Bonne, Beurre-rouge, Doyenne or St. Michael, Verte-longue, Mouille Bouche d'Automne.

Grapes; The Chaſſelas, White Muſcadine, Red Muſcadine, Black Morillon, Red Morillon, White Morillon, Currant Grape, Parſley-leafed Grape, Black, Red, and White Frontiniacs, Warner's Red Hamburgh, Black Hamburgh, St. Peter or Heſperian Grape, Orleans, Malmſey, Miller Grape, Damaſk Grape, Pearl Grape, Party-colour'd Grape, with ſome others.

Several Sorts of Figs, Walnuts, Filberts, Hazle-nuts; and againſt North Walls, ſome Currants, and Morello Cherries.

Apples; Embroidered Apple, Pearmain, Golden Rennet, Red Calville, White Calville, Courpendu, Aromatick Pippen, Rennet Griſe, with ſome others.

In the Bark-bed, the Anana's or Pine-apple.

Work to be done in the NURSERY.

The Beginning of this Month you may plant Cuttings of Laurel in ſhady Borders, obſerving to water them frequently in dry Weather, which will promote their taking Root; for at this Seaſon there is little Danger of their growing, provided they are duly watered.

You may alſo plant Cuttings of Honeyſuckles, Gooſberries, Currants, and ſeveral other hardy Trees and Shrubs, which will grow from Cuttings; for at this Seaſon they generally ſucceed better than in *Spring*.

The Ground where you intend to plant out your young Stocks, Trees and Shrubs, ſhould now be well dug, (if it was not done the former Month) that the Rain may ſoak into it, and moiſten it before the Trees are planted.

Toward the End of the Month you may tranſplant moſt Sorts of Fruit-trees, Foreſt-trees, hardy Shrubs, *&c.* obſerving to remove thoſe firſt whoſe Leaves are moſt decay'd: But if the Seaſon ſhould prove dry, they muſt be now and then watered, otherwiſe their Bark will ſhrink, and thoſe Trees which are thus early removed, will puſh out new Fibres in a Fortnight or three Weeks time: But theſe Trees ſhould be well ſupported with Stakes, otherwiſe the ſtrong Winds will blow them out of the Ground in *Winter*, and deſtroy their young Roots. You ſhould alſo lay ſome Mulch upon the Surface of the Ground about their Roots, to prevent the Froſt from penetrating the Ground, which would greatly damage the new Fibres; but this need not be done till the froſty Weather begins. The Trees thus managed will be ſo well ſettled before the ſucceeding *Summer*, that dry Weather will not injure them near ſo much as thoſe planted in the *Spring*; for which Reaſon moſt good Nurſery-men chuſe to plant out their Quarters of Stocks for Fruit, Foreſt Trees, and Flowering Shrubs at this Seaſon; becauſe where there are large Quantities, it would be very expenſive to water them. But for very moiſt Land, it will be better to defer this planting till *Spring*, becauſe the Wet in *Winter* will rot the tender Fibres of new-planted Trees.

Work to be done in the FLOWER-GARDEN.

Dig the Borders of your Flower-garden, and, if they require it, add ſome freſh Earth, or very rotten Dung to them, and plant all Sorts of hardy Flowers therein, obſerving to mix them in ſuch a manner, that there may be a regular Succeſſion of Flowers throughout the Seaſon, in the different Parts of the Garden.

Now is the Time for tranſplanting your biennial and perennial Flowers, which were ſown in the Flower-nurſery, into the Borders of the Pleaſure-garden, where they are deſigned to flower.

Your Layers of Pinks, Carnations and Sweet-Williams, which have not been tranſplanted from the old Roots the former Month, ſhould be no longer deferred; becauſe if they are not planted early in *September*, they will not have Time enough to take Root before the froſty Weather comes on, ſo that they will be in Danger of ſuffering thereby.

Plant Early Tulips in a warm Situation, where they may be defended from cold Winds, in which Places they will flower in *March*, or earlier, according as the Seaſon is more or leſs favourable.

You muſt now plant your choice Hyacinth Roots; in doing of which, you ſhould take the Earth out of the Bed about ſix Inches deep: then make the Bottom level, and draw the Lines acroſs at the Diſtance which the Roots are to be placed, that they may ſtand in Rows at equal Diſtances, and then place the Roots exactly in the Middle of each Square, and lay the Earth on them gently, being careful not to diſplace the Roots; the Beds muſt be fill'd up about five Inches thick with Earth, above the Top of the Bulbs.

Your Box-edgings which are grown too thick, ſhould now be taken up and parted, and planted down again; and thoſe Edgings which were planted the laſt Seaſon, and have not ſucceeded well, may now be repaired.

Prepare your Beds for the choice Anemonies, Ranunculus's, and Tulips, the Beginning of this Month, if it was not done the laſt; for the Earth ſhould be allowed ſome Time to ſettle, before the Roots are planted, otherwiſe it will ſettle unequally afterwards, when there will be Danger of loſing the Roots in thoſe Places where the Beds do ſettle in Holes, becauſe the Wet will be detained there, which will rot them.

The Beginning of the Month you ſhould plant ſome of your ordinary double Anemonies in warm Borders, where they may be ſcreened from cold Winds, in which Places they will flower early in the *Spring*, provided the Seaſon proves favourable.

Slip and plant out Polyanthus's, Primroſes, London Pride, Thrift, and all Sorts of hardy fibroſe-rooted Plants, which are propagated by parting their Roots; obſerving to cloſe the Earth faſt to their Roots when you plant them, otherwiſe the Worms will draw them out of the Ground.

Cut down the Stalks of ſuch Flowers as are decay'd, and if you do not tranſplant them, dig the Ground about them, and add ſome rotten Dung or freſh Earth to the Borders, which will greatly ſtrengthen their Roots.

You may yet ſow the Seeds of Iris's, Tulips, Crown Imperials, Hyacinths, Fritillaria's, Colchicums, Cyclamens, Ranunculus's, Anemonies, and moſt other bulboſe or tuberoſe-rooted Flowers, though it were better if done the Middle of the laſt Month, eſpecially if the Seaſon was moiſt, otherwiſe it is as well this Month, provided it be done early. Theſe Seeds ſhould be ſown in Pots or Tubs, filled with light freſh Earth, and the Seeds ſhould be ſown pretty thick, obſerving not to cover them too thick with Earth, eſpecially the Ranunculus's and Anemonies, whoſe Seeds are very thin, and ſubject to rot, if buried too deep. Theſe Pots muſt be placed to have the Morning Sun until the Beginning of the next Month, when they muſt be removed into a warmer Situation. You muſt alſo obſerve, if the Seaſon ſhould prove dry, to refreſh them gently with Water.

Sow the Seeds of Auricula's and Polyanthus's, in Pots or Boxes of light rich Earth, being very careful not to bury the Seeds too deep, which often deſtroys them, or at leaſt will cauſe them to remain in the Ground until the ſecond *Spring*, before the Plants will come up.

Toward the latter End of the Month, you may plant your choice Anemonies, Ranunculus's, and Tulips, obſerving always to do it in ſhowry Weather, when the Earth is not over dry; for if it ſhould continue dry Weather any conſiderable Time after the Roots are planted, they will grow mouldy, and decay. Theſe Roots muſt be planted about four Inches aſunder, and the Anemonies and Ranunculus's ſhould be covered about two Inches with Earth, over the Top of their Roots; but the Tulips ſhould have at leaſt ſix Inches of Earth above their Roots, which will cauſe them to flower very ſtrong.

If the Seaſon ſhould prove very wet, you ſhould ſhelter your Pots of choice Auricula's and Carnations therefrom, or elſe lay the Pots down on one Side, that the Wet may run off; for great Rains at this Seaſon will fill the Mould in the Pots ſo full of Moiſture, that it will not be dry again before *Winter*, and ſo will rot your choice Flowers.

Toward the End of the Month you may tranſplant moſt Sorts of hardy flowering Trees and Shrubs, which will ſucceed better at this Seaſon than in the *Spring* upon dry Grounds, and will not require ſo much Watering the following *Summer*; for they will at this Seaſon take Root in a ſhort Time, and ſo being well rooted before the Drought of the *Spring* comes on, there will be little Danger of their miſcarrying thereby.

This is a proper Seaſon for parting and tranſplanting all the Sorts of flag-leafed Iris's, that they may be well rooted before the *Spring*, otherwiſe they will not flower well the following *Summer*. You may alſo part the Roots of the early flowering After's, and Virga Aurea's, which are beginning to wither, and plant them out into large Borders, allowing them proper Room, otherwiſe their Roots will ſpread over whatever Plants do grow near them.

Plants now in Flower in the PLEASURE-GARDEN.

Annual Stock-gillyflowers, Scabious's, Sweet-ſultan, Marvel of Peru, Female Balſamine, China Pinks, Africans, French Marygolds, Hollyhocks, Chryſanthemums, Capſicums, Lupines of ſeveral Sorts, Sweet-ſcented Peas, Tangier Peas, Double Ptarmica or Sneezingwort, True Saffron, Carthamus or Baſtard Saffron, Autumnal Crocus's, Cyclamens, Colchicums, Autumnal Hyacinth, After's of ſeveral Sorts, five or ſix Sorts of Golden Rod, Double Sopewort, Double Camomile, Larkſpurs, Tree Primroſe, Polyanthus's, Spiderwort, Auricula's, Snap-dragon, Venus Looking-glaſs, Lychnis's, Campanula's, Gentianella Autumnalis, Scarlet Bean, Oriental Perſicaria, Stramoniums, Amaranthoides, Xeranthemums, Jacea's, Oriental Mallow, Lavaterra, Dwarf Annual Stock, Ketmia Veſicaria, ſeveral Sorts of Sun-flower, Elychryſums, Red Garden Valerian, with ſome others.

Hardy Trees and Shrubs now in Flower.

Jaſmine, Monthly Roſe, Muſk Roſe, Paſſion Flower, Arbutus's, Pomegranate with double Flowers, Shrub Cinquefoil, Mallow Tree, Althæa Frutex, Ketmia Syriaca, Lauruſtinus, Honeyſuckles, Scorpion Senna, with ſome others.

Work to be done in the GREEN-HOUSE *and* STOVE.

Your tender Sorts of ſucculent Plants, which were removed out of the Stove in *Summer*, muſt now be carried in again, eſpecially if the Seaſon proves wet, or the Nights cold; for by the Favourableneſs of the Weather theſe Plants are ſometimes permitted to remain abroad until the End of this Month: when at other Times the Weather will oblige you to carry them in at the Beginning of the Month; for much Wet is very prejudicial to them, and a ſmall Morning Froſt would deſtroy them; therefore you muſt be directed by the Seaſon when to remove your Plants into the Houſe.

If the Bark-beds in which your Pine-apples are plunged, have loſt their Heat, they ſhould be refreſhed by ſtirring the Bark up with a Dung-fork, and adding ſome freſh Bark thereto, which will renew the Heat; and if the Nights prove cold, the Glaſſes ſhould be carefully covered, that the Plants may be kept in a growing State; for it is better to keep them in the Bark until the Middle of *October*, if the Seaſon be not too cold, than to place them in the Stove too early, becauſe whenever you remove them into the Stove, there muſt be Fires made every Night, which will dry the Earth in the Pots ſo faſt, that they will require to be frequently watered, which is not ſo proper for theſe Plants at this Seaſon.

Toward the latter End of this Month you ſhould remove your Orange-trees into the Green-houſe, obſerving always to do it in a dry Day, when the Leaves have no Moiſture upon them; and place them thinly in the Houſe, and as near the Windows as poſſible; for there will be no Occaſion for placing them where they are to ſtand during the *Winter*, until the Myrtles, and other hardy Plants are brought into the Houſe, which need not be done until the End of *October*, unleſs the Nights ſhould prove very cold and froſty; for the longer you can keep theſe Plants abroad, the better they will thrive, and be in leſs Danger of ſuffering in *Winter*.

Your other Kinds of exotick Plants, which are to be placed in the Stove, or in Glaſs-caſes without Fires, muſt be removed into Shelter as the Seaſon grows cold, beginning with the tendereſt firſt, and ſo proceed on to the more hardy Kinds, and never place them in exact Order until they are houſed.

The latter End of this Month, or the Beginning of the next, you ſhould prepare your Tan-beds in the Stove, to receive the tendereſt exotick Plants, which ſhould be placed therein when the Bark begins to warm; but you muſt be careful not to ſuffer the Bark to heat violently, for that would injure the Roots of the Plants, and endanger their Health; becauſe when they receive Damage at this Seaſon, it is almoſt impoſſible to recover them in *Winter*; therefore if you find the Bark too hot, you muſt not plunge your Pots therein until the Heat be abated.

When you place your exotick Plants in the Houſe, you ſhould obſerve to pick off all decayed Leaves from them, and clear their Leaves and Branches from Filth or Inſects, which, if permitted to remain upon them, will greatly injure them; and you muſt ſtir the Earth in the Pots with a ſmall Trowel, being careful not to injure the Roots of the Plants.

Plants now in Flower in the GREEN-HOUSE *and* STOVE.

Oleanders with double and ſingle Flowers, Colutea Æthiopica, Amomum Plinii, Myrtles, Tree Candy-tuft, Scabious Tree, Sedum Arboreſcens, ſeveral Sorts of Ficoides's, Cotyledons, Aloes, Indian Fig, Double Naſturtium, Spaniſh Jaſmine, Arabian Jaſmine, Yellow Indian Jaſmine, Azorian Jaſmine, Blue African Hyacinth, Guernſey Lily, Belladonna Lily, Leonurus, Cytiſſus incanus, Capers, Granadilla's, Senſitive and Humble Plants, Heliotropium arboreſcens, Amber Tree, Apocynums, Viburnums, Abutilons, Fritillaria Craſſa, Canna Indica, Bean Caper, Indian Arrowroot, African Alcea, African Groundſel Tree, Indigo, Palma Chriſti, Spurges, Euphorbium, Phyſick-nut, Elychriſums, Guidonia, Papaw, Turnera, Stramoniums, Alaternoides Africana Ericæ folio, Anemonoſpermos's, Solanums, Spartiums, Doria's, Lotus Hæmorrhoidalis, Cardinal's Flower, Caſſia's, Senna Alexandrina, Senna Spuria, Ketmia's, Phytolacca fructu minore, with ſome others.

SEPTIFOLIOUS PLANTS, are ſuch as have juſt ſeven Leaves.

SERJANIA.

This Name was given to this Genus of Plants by Father *Plumier*, who diſcovered them in *America*, in Honour to the Reverend Father *Philip Serjeant*, who was of the Order of the *Minims*, and a Perſon well verſed in the Knowledge of Botany and Phyſic.

The *Characters* are;

It hath a roſe-ſhaped Flower, conſiſting of four or more Leaves, which are placed in circular Order; from whoſe Flower-cup ariſes the Pointal, which afterward becomes a Fruit compoſed of three Cells, having three Wings, and each Cell containing one round Seed.

The *Species* are;

1. SERJANIA *ſcandens, polyphylla & racemoſa. Plum. Nov. Gen.* Climbing and branching Serjania, with many Leaves.
2. SERJANIA *ſcandens enneaphylla & racemoſa. Plum. Nov. Gen.* Climbing and branching Serjania, with nine Leaves.
3. SERJANIA *ſcandens, triphylla & racemoſa. Plum. Nov. Gen.* Climbing and branching Serjania, with three Leaves.

Theſe Plants were found by the late Dr. *William Houſtoun*, at *La Vera Cruz* and *Campechy*; where they grow to a great Height, whenever they grow near large Trees to ſupport them; for they have Tendrils by which they faſten themſelves to whatever Trees grow near them.

They may be propagated either by Seeds, or from Layers; for if their Branches are laid in the Ground in the Spring, they will make good Roots before *Winter*; ſo may be taken off from the old Plants, and planted into ſeparate Pots.

If they are propagated by Seeds, (which muſt be obtained from the Countries of their natural Growth, for they do not perfect them in *England*) they muſt be ſown on a Hot-bed early in the *Spring*; and when the Plants are come up, and are fit to tranſplant, they ſhould be each put into a ſeparate Pot, filled with light freſh Earth, and plunged into a moderate Hot-bed of Tanners-bark, obſerving to ſhade them until they have taken new Root; after which Time they ſhould have a large Share of free Air admitted to them every Day, when the Weather is warm, otherwiſe they will draw up too weak. As theſe Plants advance ſo their Branches muſt be ſupported by Stakes, to prevent their trailing over other Plants, which grow near them; and when their Shoots are too tall to remain under the common Frames, they ſhould be ſhifted into larger Pots, and plunged into the Bark-bed in the Stove; where they muſt be placed on the Backſide, with *Granadilla's* and other climbing Plants, which ſhould be ſupported by an Eſpalier, on which they will climb to the Top of the Stove, and make a Variety, as their Leaves always remain green.

In the *Summer* Seaſon, when the Weather is warm, they ſhould have a great Share of free Air admitted to them, by drawing down the Glaſſes of the Stove every Day; but they are too tender to thrive in the open Air in *England*, even in the middle of *Summer*; ſo they ſhould be conſtantly kept in Stove, where they ſhould have a moderate Degree of Warmth in winter, in which they will thrive better than in a greater Share of Heat.

SERPYLLUM, [ſo call'd of *ſerpere*, Lat. to *creep*, becauſe while it is growing, it creeps ſo as to over-run whole Mountains] Mother of Thyme.

The *Characters* are;

It hath trailing Branches, which are not ſo woody and hard as thoſe of Thyme, but in every other reſpect is the ſame.

The *Species* are;

1. SERPYLLUM *vulgare majus, flore purpureo. C. B. P.* Greater common Mother of Thyme, with a purple Flower.
2. SERPYLLUM *vulgare minus. C. B. P.* Common ſmaller Mother of Thyme.
3. SERPYLLUM *vulgare, flore amplo. Raii Syn.* Common Mother of Thyme, with a large Flower.
4. SERPYLLUM *citratum. Ger. Emac.* Lemon Thyme.
5. SERPYLLUM *odore juglandis. J. B.* Mother of Thyme ſmelling like Walnuts.
6. SERPYLLUM *vulgare hirſutum. Raii Syn.* Hairy wild Thyme.
7. SERPYLLUM *latifolium hirſutum. C. B. P.* Broad-leav'd hairy wild Thyme.
8. SERPYLLUM *vulgare majus, flore albo. C.B.P.* Greater wild Thyme, with a white Flower.
9. SERPYLLUM *vulgare minus, folio ex albo & viridi vario. H. L.* Leſſer wild Thyme, with variegated Leaves.

The eight firſt mention'd Sorts do grow wild upon Heaths, and other large open Places, in divers Parts of *England*, where in the *Summer* Time, when they are in Flower, they afford an agreeable Proſpect, and being trod upon, do emit a grateful aromatick Scent. Their common Places of Growth are upon ſmall Hillocks, where the Ground is dry and uncultivated, where in a ſhort Time, they propagate themſelves plentifully, both from Seeds and by their trailing Branches, which take Root at their Joints, and ſo extend themſelves every way.

There are but two of theſe *Species* commonly cultivated in Gardens; *viz.* the *Lemon Thyme*, and that with *ſtriped Leaves*; the firſt for its agreeable Scent, and the other for the Beauty of its variegated Leaves; theſe were formerly planted to edge Borders; but as they are very apt to ſpread, and difficult to preſerve in Compaſs, ſo they are diſuſed at preſent for that Purpoſe.

All theſe do propagate themſelves very faſt, by their trailing Branches, which ſtrike out Roots from their Joints into the Earth, and thereby make new Plants; ſo that from a Root of each, there may ſoon be a large Stock increaſed. They may be tranſplanted either in *Spring* or *Autumn*, and love an open Situation, and a dry undung'd Soil, in which they will thrive and flower exceedingly, and continue ſeveral Years.

SERRATULA, Saw-wort.

The *Characters* are;

It hath a floſculous Flower, conſiſting of ſeveral Florets, divided into many Parts reſting on the Embryo, and contained in a ſcaly Empalement, like to the greater Centaury, from which this differs in having ſmaller Heads, and from the Knapweed in having the Borders of the Leaves cut into ſmall ſharp Segments, the Teeth of a Saw.

The *Species* are;

1. SERRATULA *vulgaris, flore purpureo. C. B. P.* Common Saw-wort with a purple Flower.
2. SERRATULA *flore candido. C. B. P.* Common Saw-wort with a white Flower.
3. SERRATULA *Virginiana, foliis rigidis. Par. Bat.* Saw-wort of *Virginia*, with ſtiff Leaves.
4. SERRATULA *præalta altera, anguſto plantaginis folio. Bocc. Muſ.* The talleſt Saw-wort, with a narrow Plantain-leaf.
5. SERRATULA *præalta centauroides montana Italica. Bocc. Muſ.* The talleſt Saw-wort of the *Italian* Mountains, reſembling Centaury.
6. SERRATULA *Noveboracenſis altiſſima, foliis doriæ mollibus ſubincanis. Par. Bat.* The talleſt Saw-wort of *New York*, with ſoft doria Leaves, which are white on the Underſide.

The firſt and ſecond Sorts are pretty common in the Woods, in divers Parts of *England*, ſo are ſeldom admitted into Gardens; but as they are Plants which will grow in the cloſeſt Shade, they may be introduced to plant under Trees in large Plantations, where they will thrive and flower extremely well, and add to the Variety. Theſe Plants are eaſily propagated by parting of their Roots in *Autumn*, ſo as that they may be well rooted before *Spring*; otherwiſe they will not flower very ſtrong the following Seaſon.

The third and ſixth Sorts are Natives of North *America*, where they are very common in their Woods. Theſe are hardy Plants, and will endure the Cold of our ordinary *Winters* very well; but if they are planted in the full Ground, they ſhould have a moiſt light Soil; otherwiſe they will periſh in dry Weather, unleſs they are duly watered. The third Sort ſeldom riſes above two Feet High in this Country, but the ſixth Sort will ſometimes grow to the Height of five or ſix Feet, if it is planted in a moiſt rich Soil; but this laſt Sort is very late in Flowering, ſo that if the Seaſon proves cold, it many times will not flower in this Country. Theſe are both abiding Plants, which may be propagated by parting of their Roots; the beſt Time for which is in the *Spring*, juſt before they begin to ſhoot; for as theſe continue growing in *Autumn*, until the Froſt puts a Stop to them, it would be dangerous to tranſplant them in *Winter*.

The fourth and fifth Sorts grow wild in the mountainous Parts of *Italy* and *Spain*, but are hardy enough to reſiſt the Cold of this Climate; ſo may be intermixed with the other Sorts, in Woods or under Plantations of Trees, where they will make an agreeable Variety. Theſe Plants may be propagated by Seeds, which ſhould be ſown early in the *Spring* on a Border of freſh Earth; and when the Plants appear, they ſhould be carefully weeded, and in very dry Weather they muſt be frequently watered; which will bring them forward, ſo that they will ſoon be fit to tranſplant. When they are removed, they muſt be planted in a ſhady Border, about ſix Inches apart, and kept duly watered, until they have taken new Root; after which Time they will require no farther Care, but to keep them clear from Weeds, till *Michaelmas*. when they ſhould be tranſplanted where they are deſigned to remain.

SESAMUM, Oily-grain.

The *Characters* are;

The Flowers are produced from the Wings of the Leaves, without any Foot-ſtalk; the Flower-cup conſiſts of one Leaf, divided into five long ſlender Segments; the Flower is of one Leaf, in Shape like thoſe of the Fox-glove; the Pointal, which riſes in the Middle of the Flower, afterwards becomes an oblong four-corner'd Pod, divided into four diſtinct Cells, which are replete without eſculent Seeds.

The *Species* are;

1. Sesamum. *J. B.* Common Oily-grain.

2. Sesamum *alterum, foliis trifidis, Orientale, ſemine obſcuro. Pluk. Phyt.* Another Eaſter Oily-grain, with trifid Leaves, and dark-colour'd Seeds.

3. Sesamum *Orientale trifidum, flore niveo. Hort. Compt.* Eaſtern Oily-grain, with trifid Leaves, and white Flowers.

Theſe three Sorts are often promiſcuouſly cultivated in the Fields of *Syria*, *Egypt*, *Candia*, &c. where the Inhabitants uſe the Seeds for Food; and of late Years theſe Plants have been introduced in *Carolina*, where they ſucceed extremely well: the Inhabitants of that Country make an Oil from the Seed, which will keep many Years, and not take any rancid Smell or Taſte, but in two Years becomes quite mild; ſo that when the warm Taſte of the Seed, which is in the Oil when firſt drawn, is worn off, they uſe it as Sallad Oil, and for all the Purpoſes of Sweet Oil.

In *England* theſe Plants are preſerved in Botanick Gardens, as Curioſities: their Seeds muſt be ſown in the *Spring* upon a Hot-bed; and when the Plants are come up they muſt be tranſplanted into a freſh Hot-bed, to bring them forward; after they have acquired a tolerable Degree of Strength, they ſhould be planted into Pots fill'd with rich light ſandy Soil, and plunged into another Hot-bed, managing them as hath been directed for *Amaranthus's*, to which I ſhall refer the Reader, to avoid Repetition: For if theſe Plants are not brought forward thus in the former Part of the *Summer*, they will not produce good Seeds in this Country; tho' after they have flower'd, if the Seaſon is favourable, they may be expoſed in a warm Situation with other annual Plants. When theſe Plants have perfected their Seeds, they decay, and never continue longer than one Seaſon.

The Seed of the firſt Sort is mention'd in the Liſt of *Officinal Simples* in the *College Diſpenſatory*, but is rarely uſed in Medicine in *England*. From Nine Pounds of this Seed, which came from *Carolina*, there were upwards of two Quarts of Oil produced, which is as great a Quantity as hath been known to be drawn from any Vegetable whatever; and this, I ſuppoſe, might occaſion its being call'd *Oily-grain*.

SESELI, Wild-ſpignel.

The *Characters* are;

It hath a roſe and umbellated Flower, conſiſting of ſeveral Leaves placed in a Circle, and reſting on the Empalement, which afterward becomes a Fruit, compoſed of two long Seeds, which are channelled. To theſe Notes muſt be added, That the Leaves are broader and ſhorter than thoſe of Fennel.

The *Species* are;

1. Seseli *perenne, folio glauco breviori. Vaill.* Perennial Wild-ſpignel, with a ſhorter ſea-green Leaf.

2. Seseli *perenne, folio glauco longiori. Vaill.* Perennial Wild-ſpignel, with a longer ſea-green Leaf.

3. Seseli *quæ ferulæ facie, thapſia ſive Turbith Gallorum. J. B. Boerh. Ind. alt.* Wild-ſpignel, with the Face of Giant-fennel, ſuppoſed to be the Turbith of the *Gauls*.

4. Seseli, *quæ Saxifraga Pannonica. Cluſ. Hiſt. Boerh. Ind. alt.* Wild-Spignel, or the *Portugal* Saxifrage of *Cluſius*.

The three firſt Sorts are abiding Plants, whoſe Roots will continue ſeveral Years; but the fourth Sort is a biennial Plant, which periſhes ſoon after it has perfected its Seeds.

Theſe may be propagated by ſowing of their Seeds, which is beſt done in the *Autumn*; for when the Seeds are ſown in the *Spring*, they frequently lie in the Ground till the next Year, before the Plants will appear; whereas thoſe which are ſown in the *Autumn* always riſe the following *Spring*. Theſe Seeds ſhould be ſown in Drills, about eighteen Inches aſunder, in a Bed of freſh Earth, where they are deſigned to remain; and in the *Spring*, when the Plants come up, they ſhould be thinned where they are too cloſe, leaving them about ſix Inches Diſtance in the Rows; after this the Plants will require no farther Care, but to keep them conſtantly clear from Weeds, and the ſecond Seaſon they will produce Seeds. Theſe Sorts which are permitted to remain after they have ſeeded, ſhould have the Ground gently dug every *Spring* between the Rows, to looſen the Earth; but there ſhould be Care taken not to injure their Roots with the Spade. The Plants love a moiſt Soil, for when they are ſown on a dry Soil, they do not thrive near ſo well, and ſeldom perfect their Seeds, unleſs the Seaſon proves moiſt, or they are duly watered.

SHERARDIA.

This Name was given to this Genus of Plants by Mr. *Vaillant*, who was Profeſſor of Botany at *Paris*, in Honour to Dr. *William Sherard*, who was the moſt famous Botaniſt of the Age.

The *Characters* are;

It hath a labiated Flower conſiſting of one Leaf, which is divided into five Parts at the Brim; the upper Lip being divided into two, and the under Lip into three Parts: the Ovary, which is at the Bottom of the Flower-cup, afterward becomes a dry Capſule, containing two oblong Seeds. To theſe Notes may be added, That the Leaves grow oppoſite by Pairs.

The *Species* are;

1. Sherardia *repens, nodiflora. Vaill. Nov. Gen.* Creeping Sherardia, with Flowers growing in round Heads.

2. Sherardia *repens, folio ſubrotundo craſſo, nodiflora. Vaill. Nov. Gen.* Creeping Sherardia, with a roundiſh thick Leaf, and Flowers collected in round Heads.

3. Sherardia *incana nodiflora. Vaill. Nov. Gen.* Hoary Sherardia, with Flowers collected into round Heads.

4. Sherardia *nodiflora, ſtœchadis ſerrati folii folio. Vaill. Nov. Gen.* Round-flowering Sherardia, with a Leaf like the ſawed-leaved Stœchas.

5. Sherardia *ocymi folio lanuginoſo, flore purpureo. Vaill. Nov. Gen.* Woolly Sherardia, with a Baſil-leaf, and a purple Flower.

6. Sherardia *teucrii folio, flore purpureo. Vaill. Nov. Gen.* Sherardia with a Tree-germander Leaf, and a purple Flower.

7. Sherardia *fruteſcens, teucrii folio, flore cæruleo purpuraſcente ampliſſimo. Vaill. Nov. Gen.* Shrubby Sherardia, with a Tree-germander Leaf, and a large purpliſh blue Flower.

8. Sherardia *teucrii folio, flore coccineo. Vaill. Nov. Gen.* Sherardia with a Tree-germander Leaf, and a ſcarlet Flower.

9. Sherardia *ſpicata, folio anguſto ſerrato, flore cæruleo. Houſt.* Spiked Sherardia, with a narrow ſawed Leaf, and a blue Flower.

10. Sherardia *ſpicata, flore purpureo, ſeminibus majoribus, longioribus & laxius digeſtis. Houſt.* Spiked Sherardia, with a purple Flower, and larger longer Seeds, which are looſely diſpoſed in the Spike.

11. SHERARDIA *verbenæ folio ſubrotundo craſſo, floribus cæruleis, ſpicâ longiſſimâ & craſſiſſimâ. Houſt.* Sherardia with a thick roundiſh vervain Leaf, and blue Flowers, growing in a very long thick Spike.

12. SHERARDIA *foliis oblongis ſerratis, flore cæruleo, ſpicâ longiſſimâ. Houſt.* Sherardia with oblong ſawed Leaves, a blue Flower, and a very long Spike.

13. SHERARDIA *arboreſcens nodiflora, foliis rugoſis & ſerratis, flore purpureo. Houſt.* Tree-like Sherardia, with rough ſawed Leaves, and purple Flowers growing in a round Head.

The firſt of theſe Plants is a Native of *Europe*, ſo will thrive in the open Air in this Country. The Seeds of this Kind ſhould be ſown in the *Spring*, on a Bed of light freſh Earth, in a warm Situation, and where the Plants are deſigned to remain (for they do not bear tranſplanting very well). And when the Plants are come up, they ſhould be thinned ſo as to leave them a Foot aſunder; and if they are kept clear from Weeds, they will require no farther Care. The Branches of this Plant trail on the Ground, and ſend forth Roots from their Joints, whereby they may be propagated; but if they are not confined, they will not produce many Flowers.

All the other ſorts are Natives of the warm Parts of *America*, ſo are too tender to thrive in the open Air of *England*; but as moſt of them are annual, they may be raiſed by ſowing of their Seeds on a Hot-bed; and if the Plants are brought forward early in the *Spring*, they will flower and produce ripe Seeds before *Winter*.

The ſecond ſort was found by Dr. *William Houſtoun*, growing plentifully in *Jamaica*. This Plant trails its Branches on the Ground, emits Roots from the Joint as the former ſort, ſo doth not produce many Flowers.

The fourth ſort was found in great Plenty at *La Vera Cruz*, by Dr. *Houſtoun*, as were the ninth, tenth, eleventh, twelfth and thirteenth ſorts, at *Campechy*, by the ſame Gentleman.

The third, fifth and ſixth ſorts, grow plentifully in *Jamaica*, and ſeveral other Places in the *Weſt-Indies*, from whence I have received their Seeds.

The ſeventh Sort is a very ſpacious Plant which merits a Place in every good Collection of Plants. This produces long Spikes of large blue Flowers, which continue a long Time, and make a fine Appearance. This is alſo an annual Plant, notwithſtanding it has the Epithet of Shrubby given to it; for it always flowers the ſame *Summer* it is raiſed: but if it is not brought forward early in the *Spring*, and conſtantly kept in the Stove or Glaſs-caſe, it will not perfect Seeds in this Country. The Seeds of this Kind were ſent to *England* by Mr. *Robert Millar*, Surgeon, who gathered them near *Panama*.

The thirteenth ſort riſes to be nine or ten Feet high, and hath a woody Stem. This will abide many Years, provided it is preſerved in a Stove in *Winter*. During the *Summer* Seaſon, this ſort may be placed in the open Air in a warm Situation, and in hot Weather muſt be frequently watered; but in *Autumn*, when the Nights grow cold, the Plants muſt be removed into the Stove, and in *Winter* they ſhould have a moderate ſhare of Heat; with which Management the Plants will thrive very well.

All theſe Plants are propagated by Seeds, which ſhould be ſown early in the *Spring* on a moderate Hot-bed; and when the Plants are come up, they ſhould be each tranſplanted into a ſeparate ſmall Pot, filled with light rich Earth, and plunged into a moderate Hot-bed of Tanners-bark, obſerving to ſhade them from the Sun every Day, until they have taken new Root; after which Time they ſhould have a large ſhare of free Air admitted to them in warm Weather, and they muſt be frequently watered. When the Plants have filled theſe Pots with their Roots, they muſt be ſhifted into larger Pots; and if there is Room for the Plants to grow under the Glaſſes of the Hot-bed, without being ſcorched by the Sun, they ſhould be plunged into the ſame Bed again; but if there is not Room, they muſt be placed in the Stove, where they may have Room to grow in Height. In *July* theſe ſorts which are annual, will begin to flower, and their Seeds will ripen the Beginning of *September*.

SICYOIDES, Single-ſeeded Cucumber.

The *Characters* are:

It hath an expanded bell-ſhaped Flower, conſiſting of one Leaf, which is cut into ſeveral Segments at the Brim; of theſe Flowers, ſome are Male, which adhere to no Embryo; and others are Female, which reſt on the young Fruit, which is afterward inlarged to the ſize of an almond Kernel, and is flat and prickly, containing one Seed of the ſame ſhape.

The *Species* are;

1. SICYOIDES *Americana, fructu echinato, foliis angulatis. Inſt. R. H. American* Sicyoides, with a prickly Fruit, and angular Leaves.

2. SICYOIDES *Americana, fructu echinato, foliis laciniatis. Plum. American* Sicyoides, with a prickly Fruit, and jagged Leaves.

Theſe Plants are preſerved in ſome curious Gardens, for the ſake of Variety; but as they have little Beauty, and are not uſeful, ſo they are not much cultivated in *England*. They are both annual Plants, which may be propagated by ſowing of their Seeds in the Beginning of *April*, on a Border of freſh Earth, in the Place where they are deſigned to remain; and in about a Fortnight's Time the Plants will appear; which at firſt are very like Cucumber-plants, and, as they grow, will trail on the Ground, and faſten themſelves to whatever Plants grow near them, by their Tendrils; ſo that they ſhould be either ſown near a Hedge, where they may climb up, or be allowed a conſiderable ſhare of Room, otherwiſe they will run over the Plants which are near them. When the Plants are come up, they will require no farther Care, but to keep them clear from Weeds, and to thin them where they grow too cloſe together. In *June* they will produce their Flowers, and in *Auguſt* their Seeds will ripen, which, if permitted to ſcatter, will produce a Supply of young Plants the following *Spring*, without any Care.

SIDERATION, a Blaſting of Trees or Plants by an Eaſterly Wind, or exceſſive Heat or Drought.

SIDERITIS; [of σίδηρος, *Iron*, q. *Iron-herb*, ſo *Dioſcorides* calls thoſe Herbs that are good againſt Wounds made by the Sword: It is alſo called *Ferrum Matrix*, on the ſame Account. It is alſo called *Herba Judaica*, becauſe the *Jews* in old Time made uſe of this Herb in Medicine] Ironwort.

The *Characters* are;

It is a Plant with a labiated Flower, conſiſting of one Leaf, whoſe upper Lip or Creſt is upright, but the under Lip or Beard is divided into three Parts; out of the Flower-cup riſes the Pointal, attended, as it were, by four Embryo's, which afterwards turn to ſo many oblong Seeds, ſhut up in a Husk, which was before the Flower-cup: To theſe Marks muſt be added, the Flowers growing in Whorles at the Wings of the Leaves, which are cut like a Creſt, and differ from the other Leaves of the Plant.

The *Species* are;

1. SIDERITIS *hirſuta procumbens. C. B. P.* Hairy trailing Ironwort.

2. SIDERITIS *Alpina, hyſſopi folio. C. B. P.* Hyſſop-leafed Ironwort of the Alps.

3. SIDERITIS *Orientalis, phlomidis folio. T. Cor.* Eaſtern Ironwort, with a Phlomis Leaf.

4. SIDERITIS *Anglica, ſtrumoſa radice. Park. Theat.* Engliſh Ironwort, with a ſtrumoſe Root, *commonly called* Clowns All-heal.

5. SIDERITIS *arvenſis rubra. Park. Theat.* Narrow-leafed All-heal *or* Ironwort.

6. SIDERITIS *foliis hirſutis, profunde crenatis. C. B. P.* Ironwort *or* All-heal, with hairy crenated Leaves.

7. SIDERITIS *Hiſpanica erecta, folio anguſtiore. Inſt. R. H.* Upright Spaniſh All-heal, with a narrow Leaf.

8. SIDERITIS *Hiſpanica crenata procumbens, flore albo, major. Inſt. R. H.* Greater trailing Spaniſh All-heal, with a white Flower.

9. SIDERITIS *Hiſpanica bituminoſa anguſtifolia crenata. Inſt. R. H.* Spaniſh All-heal, with a bituminous Scent, and a narrow crenated Leaf.

10. SIDERITIS *Hiſpanica fœtidiſſima glabra, flore purpuraſcente, & comâ caneſcente. Inſt. R. H.* Spaniſh ſtinking ſmooth All-heal, with a purpliſh Flower, and whitiſh Tops.

11. SIDERITIS *Hiſpanica fruteſcens, ſeu lignoſior. Inſt. R. H.* Shrubby or more woody Spaniſh All-heal.

12. SIDERITIS *Pyrenaica hyſſopifolia minima procumbens. Inſt. R. H.* The leaſt trailing hyſſop-leafed All-heal of the Pyrenees.

13. SIDERITIS *montana, trifido folio. Barrel. Icon.* Mountain All-heal, with a trifid Leaf.

they ſhould have a moiſt light Soil; otherwiſe they will periſh in dry Weather, unleſs they are duly watered. The third Sort ſeldom riſes above two Feet High in this Country, but the ſixth Sort will ſometimes grow to the Height of five or ſix Feet, if it is planted in a moiſt rich Soil; but this laſt Sort is very late in Flowering, ſo that if the Seaſon proves cold, it many times will not flower in this Country. Theſe are both abiding Plants, which may be propagated by parting of their Roots; the beſt Time for which is in the *Spring*, juſt before they begin to ſhoot; for as theſe continue growing in *Autumn*, until the Froſt puts a Stop to them, it would be dangerous to tranſplant them in *Winter*.

The fourth and fifth Sorts grow wild in the mountainous Parts of *Italy* and *Spain*, but are hardy enough to reſiſt the Cold of this Climate; ſo may be intermixed with the other Sorts, in Woods or under Plantations of Trees, where they will make an agreeable Variety. Theſe Plants may be propagated by Seeds, which ſhould be ſown early in the *Spring* on a Border of freſh Earth; and when the Plants appear, they ſhould be carefully weeded, and in very dry Weather they muſt be frequently watered; which will bring them forward, ſo that they will ſoon be fit to tranſplant. When they are removed, they muſt be planted in a ſhady Border, about ſix Inches apart, and kept duly watered, until they have taken new Root; after which Time they will require no farther Care, but to keep them clear from Weeds, till *Michaelmas*, when they ſhould be tranſplanted where they are deſigned to remain.

SESAMUM, Oily-grain.

The *Characters* are;

The Flowers are produced from the Wings of the Leaves, without any Foot-ſtalk; the Flower-cup conſiſts of one Leaf, divided into five long ſlender Segments; the Flower is of one Leaf, in Shape like thoſe of the Fox-glove; the Pointal, which riſes in the Middle of the Flower, afterwards becomes an oblong four-corner'd Pod, divided into four diſtinct Cells, which are replete without eſculent Seeds.

The *Species* are;

1. SESAMUM. *J. B.* Common Oily-grain.

2. SESAMUM *alterum, foliis trifidis, Orientale, ſemine obſcuro. Pluk. Phyt.* Another Eaſter Oily-grain, with trifid Leaves, and dark-colour'd Seeds.

3. SESAMUM *Orientale trifidum, flore niveo. Hort. Compt.* Eaſtern Oily-grain, with trifid Leaves, and white Flowers.

Theſe three Sorts are often promiſcuouſly cultivated in the Fields of *Syria*, *Egypt*, *Candia*, &c. where the Inhabitants uſe the Seeds for Food; and of late Years theſe Plants have been introduced in *Carolina*, where they ſucceed extremely well: the Inhabitants of that Country make an Oil from the Seed, which will keep many Years, and not take any rancid Smell or Taſte, but in two Years becomes quite mild; ſo that when the warm Taſte of the Seed, which is in the Oil when firſt drawn, is worn off, they uſe it as Sallad Oil, and for all the Purpoſes of Sweet Oil.

In *England* theſe Plants are preſerved in Botanick Gardens, as Curioſities: their Seeds muſt be ſown in the *Spring* upon a Hot-bed; and when the Plants are come up they muſt be tranſplanted into a freſh Hot-bed, to bring them forward; after they have acquired a tolerable Degree of Strength, they ſhould be planted into Pots fill'd with rich light ſandy Soil, and plunged into another Hot-bed, managing them as hath been directed for *Amaranthus's*, to which I ſhall refer the Reader, to avoid Repetition: For if theſe Plants are not brought forward thus in the former Part of the *Summer*, they will not produce good Seeds in this Country; tho' after they have flower'd, if the Seaſon is favourable, they may be expoſed in a warm Situation with other annual Plants. When theſe Plants have perfected their Seeds, they decay, and never continue longer than one Seaſon.

The Seed of the firſt Sort is mention'd in the Liſt of *Officinal Simples* in the *College Diſpenſatory*, but is rarely uſed in Medicine in *England*. From Nine Pounds of this Seed, which came from *Carolina*, there were upwards of two Quarts of Oil produced, which is as great a Quantity as hath been known to be drawn from any Vegetable whatever; and this, I ſuppoſe, might occaſion its being call'd *Oily-grain*.

SESELI, Wild-ſpignel.

The *Characters* are;

It hath a roſe and umbellated Flower, conſiſting of ſeveral Leaves placed in a Circle, and reſting on the Empalement, which afterward becomes a Fruit, compoſed of two long Seeds, which are channelled. To theſe Notes muſt be added, That the Leaves are broader and ſhorter than thoſe of Fennel.

The *Species* are;

1. SESELI *perenne, folio glauco breviori. Vaill.* Perennial Wild-ſpignel, with a ſhorter ſea-green Leaf.

2. SESELI *perenne, folio glauco longiori. Vaill.* Perennial Wild-ſpignel, with a longer ſea-green Leaf.

3. SESELI *quæ ferulæ facie, thapſia ſive Turbith Gallorum. J. B. Boerh. Ind. alt.* Wild-ſpignel, with the Face of Giant-fennel, ſuppoſed to be the Turbith of the *Gauls*.

4. SESELI, *quæ Saxifraga Pannonica. Cluſ. Hiſt. Boerh. Ind. alt.* Wild-Spignel, or the *Portugal* Saxifrage of *Cluſius*.

The three firſt Sorts are abiding Plants, whoſe Roots will continue ſeveral Years; but the fourth Sort is a biennial Plant, which periſhes ſoon after it has perfected its Seeds.

Theſe may be propagated by ſowing of their Seeds, which is beſt done in the *Autumn*; for when the Seeds are ſown in the *Spring*, they frequently lie in the Ground till the next Year, before the Plants will appear; whereas thoſe which are ſown in the *Autumn* always riſe the following *Spring*. Theſe Seeds ſhould be ſown in Drills, about eighteen Inches aſunder, in a Bed of freſh Earth, where they are deſigned to remain; and in the *Spring*, when the Plants come up, they ſhould be thinned where they are too cloſe, leaving them about ſix Inches Diſtance in the Rows; after this the Plants will require no farther Care, but to keep them conſtantly clear from Weeds, and the ſecond Seaſon they will produce Seeds. Theſe Sorts which are permitted to remain after they have ſeeded, ſhould have the Ground gently dug every *Spring* between the Rows, to looſen the Earth; but there ſhould be Care taken not to injure their Roots with the Spade. The Plants love a moiſt Soil, for when they are ſown on a dry Soil, they do not thrive near ſo well, and ſeldom perfect their Seeds, unleſs the Seaſon proves moiſt, or they are duly watered.

SHERARDIA.

This Name was given to this Genus of Plants by Mr. *Vaillant*, who was Profeſſor of Botany at *Paris*, in Honour to Dr. *William Sherard*, who was the moſt famous Botaniſt of the Age.

The *Characters* are;

It hath a labiated Flower conſiſting of one Leaf, which is divided into five Parts at the Brim; the upper Lip being divided into two, and the under Lip into three Parts: the Ovary, which is at the Bottom of the Flower-cup, afterward becomes a dry Capſule, containing two oblong Seeds. To theſe Notes may be added, That the Leaves grow oppoſite by Pairs.

The *Species* are;

1. SHERARDIA *repens, nodiflora. Vaill. Nov. Gen.* Creeping Sherardia, with Flowers growing in round Heads.

2. SHERARDIA *repens, folio ſubrotundo craſſo, nodiflora. Vaill. Nov. Gen.* Creeping Sherardia, with a roundiſh thick Leaf, and Flowers collected in round Heads.

3. SHERARDIA *incana nodiflora. Vaill. Nov. Gen.* Hoary Sherardia, with Flowers collected into round Heads.

4. SHERARDIA *nodiflora, ſtœchadis ſerrati folii folio. Vaill. Nov. Gen.* Round-flowering Sherardia, with a Leaf like the ſawed-leaved Stœchas.

5. SHERARDIA *ocymi folio lanuginoſo, flore purpureo. Vaill. Nov. Gen.* Woolly Sherardia, with a Baſil-leaf, and a purple Flower.

6. SHERARDIA *teucrii folio, flore purpureo. Vaill. Nov. Gen.* Sherardia with a Tree-germander Leaf, and a purple Flower.

7. SHERARDIA *fruteſcens, teucrii folio, flore cæruleo purpuraſcente ampliſſimo. Vaill. Nov. Gen.* Shrubby Sherardia, with a Tree-germander Leaf, and a large purpliſh blue Flower.

8. SHERARDIA *teucrii folio, flore coccineo. Vaill. Nov. Gen.* Sherardia with a Tree-germander Leaf, and a ſcarlet Flower.

9. SHERARDIA *ſpicata, folio anguſto ſerrato, flore cæruleo. Houſt.* Spiked Sherardia, with a narrow ſawed Leaf, and a blue Flower.

10. SHERARDIA *ſpicata, flore purpureo, ſeminibus majoribus, longioribus & laxius digeſtis. Houſt.* Spiked Sherardia, with a purple Flower, and larger longer Seeds, which are looſely diſpoſed in the Spike.

11. SHERARDIA *verbenæ folio ſubrotundo craſſo, floribus cæruleis, ſpicâ longiſſimâ & craſſiſſimâ. Houſt.* Sherardia with a thick roundiſh vervain Leaf, and blue Flowers, growing in a very long thick Spike.

12. SHERARDIA *foliis oblongis ſerratis, flore cæruleo, ſpicâ longiſſimâ. Houſt.* Sherardia with oblong ſawed Leaves, a blue Flower, and a very long Spike.

13. SHERARDIA *arboreſcens nodiflora, foliis rugoſis & ſerratis, flore purpureo. Houſt.* Tree-like Sherardia, with rough ſawed Leaves, and purple Flowers growing in a round Head.

The firſt of theſe Plants is a Native of *Europe*, ſo will thrive in the open Air in this Country. The Seeds of this Kind ſhould be ſown in the *Spring*, on a Bed of light freſh Earth, in a warm Situation, and where the Plants are deſigned to remain (for they do not bear tranſplanting very well). And when the Plants are come up, they ſhould be thinned ſo as to leave them a Foot aſunder; and if they are kept clear from Weeds, they will require no farther Care. The Branches of this Plant trail on the Ground, and ſend forth Roots from their Joints, whereby they may be propagated; but if they are not confined, they will not produce many Flowers.

All the other ſorts are Natives of the warm Parts of *America*, ſo are too tender to thrive in the open Air of *England*; but as moſt of them are annual, they may be raiſed by ſowing of their Seeds on a Hot-bed; and if the Plants are brought forward early in the *Spring*, they will flower and produce ripe Seeds before *Winter*.

The ſecond ſort was found by Dr. *William Houſtoun*, growing plentifully in *Jamaica*. This Plant trails its Branches on the Ground, emits Roots from the Joint as the former ſort, ſo doth not produce many Flowers.

The fourth ſort was found in great Plenty at *La Vera Cruz*, by Dr. *Houſtoun*, as were the ninth, tenth, eleventh, twelfth and thirteenth ſorts, at *Campechy*, by the ſame Gentleman.

The third, fifth and ſixth ſorts, grow plentifully in *Jamaica*, and ſeveral other Places in the *Weſt-Indies*, from whence I have received their Seeds.

The ſeventh Sort is a very ſpacious Plant which merits a Place in every good Collection of Plants. This produces long Spikes of large blue Flowers, which continue a long Time, and make a fine Appearance. This is alſo an annual Plant, notwithſtanding it has the Epithet of Shrubby given to it; for it always flowers the ſame *Summer* it is raiſed: but if it is not brought forward early in the *Spring*, and conſtantly kept in the Stove or Glaſs-caſe, it will not perfect Seeds in this Country. The Seeds of this Kind were ſent to *England* by Mr. *Robert Millar*, Surgeon, who gathered them near *Panama*.

The thirteenth ſort riſes to be nine or ten Feet high, and hath a woody Stem. This will abide many Years, provided it is preſerved in a Stove in *Winter*. During the *Summer* Seaſon, this ſort may be placed in the open Air in a warm Situation, and in hot Weather muſt be frequently watered; but in *Autumn*, when the Nights grow cold, the Plants muſt be removed into the Stove, and in *Winter* they ſhould have a moderate ſhare of Heat; with which Management the Plants will thrive very well.

All theſe Plants are propagated by Seeds, which ſhould be ſown early in the *Spring* on a moderate Hot-bed; and when the Plants are come up, they ſhould be each tranſplanted into a ſeparate ſmall Pot, filled with light rich Earth, and plunged into a moderate Hot-bed of Tanners-bark, obſerving to ſhade them from the Sun every Day, until they have taken new Root; after which Time they ſhould have a large ſhare of free Air admitted to them in warm Weather, and they muſt be frequently watered. When the Plants have filled theſe Pots with their Roots, they muſt be ſhifted into larger Pots; and if there is Room for the Plants to grow under the Glaſſes of the Hot-bed, without being ſcorched by the Sun, they ſhould be plunged into the ſame Bed again; but if there is not Room, they muſt be placed in the Stove, where they may have Room to grow in Height. In *July* theſe ſorts which are annual, will begin to flower, and their Seeds will ripen the Beginning of *September*.

SICYOIDES, Single-ſeeded Cucumber.

The *Characters* are:

It hath an expanded bell-ſhaped Flower, conſiſting of one Leaf, which is cut into ſeveral Segments at the Brim; of theſe Flowers, ſome are Male, which adhere to no Embryo; and others are Female, which reſt on the young Fruit, which is afterward inlarged to the ſize of an almond Kernel, and is flat and prickly, containing one Seed of the ſame ſhape.

The *Species* are;

1. SICYOIDES *Americana, fructu echinato, foliis angulatis. Inſt. R. H. American* Sicyoides, with a prickly Fruit, and angular Leaves.

2. SICYOIDES *Americana, fructu echinato, foliis laciniatis. Plum. American* Sicyoides, with a prickly Fruit, and jagged Leaves.

Theſe Plants are preſerved in ſome curious Gardens, for the ſake of Variety; but as they have little Beauty, and are not uſeful, ſo they are not much cultivated in *England*. They are both annual Plants, which may be propagated by ſowing of their Seeds in the Beginning of *April*, on a Border of freſh Earth, in the Place where they are deſigned to remain; and in about a Fortnight's Time the Plants will appear; which at firſt are very like Cucumber-plants, and, as they grow, will trail on the Ground, and faſten themſelves to whatever Plants grow near them, by their Tendrils; ſo that they ſhould be either ſown near a Hedge, where they may climb up, or be allowed a conſiderable ſhare of Room, otherwiſe they will run over the Plants which are near them. When the Plants are come up, they will require no farther Care, but to keep them clear from Weeds, and to thin them where they grow too cloſe together. In *June* they will produce their Flowers, and in *Auguſt* their Seeds will ripen, which, if permitted to ſcatter, will produce a Supply of young Plants the following *Spring*, without any Care.

SIDERATION, a Blaſting of Trees or Plants by an Eaſterly Wind, or exceſſive Heat or Drought.

SIDERITIS; [of σίδηρος, *Iron*, q. *Iron-herb*, ſo *Dioſcorides* calls thoſe Herbs that are good againſt Wounds made by the Sword: It is alſo called *Ferrum Matrix*, on the ſame Account. It is alſo called *Herba Judaica*, becauſe the *Jews* in old Time made uſe of this Herb in Medicine] Ironwort.

The *Characters* are;

It is a Plant with a labiated Flower, conſiſting of one Leaf, whoſe upper Lip or Creſt is upright, but the under Lip or Beard is divided into three Parts; out of the Flower-cup riſes the Pointal, attended, as it were, by four Embryo's, which afterwards turn to ſo many oblong Seeds, ſhut up in a Husk, which was before the Flower-cup: To theſe Marks muſt be added, the Flowers growing in Whorles at the Wings of the Leaves, which are cut like a Creſt, and differ from the other Leaves of the Plant.

The *Species* are;

1. SIDERITIS *hirſuta procumbens. C. B. P.* Hairy trailing Ironwort.

2. SIDERITIS *Alpina, hyſſopi folio. C. B. P.* Hyſſop-leafed Ironwort of the Alps.

3. SIDERITIS *Orientalis, phlomidis folio. T. Cor.* Eaſtern Ironwort, with a Phlomis Leaf.

4. SIDERITIS *Anglica, ſtrumoſa radice. Park. Theat.* Engliſh Ironwort, with a ſtrumoſe Root, *commonly called* Clowns All-heal.

5. SIDERITIS *arvenſis rubra. Park. Theat.* Narrow-leafed All-heal *or* Ironwort.

6. SIDERITIS *foliis hirſutis, profunde crenatis. C. B. P.* Ironwort *or* All-heal, with hairy crenated Leaves.

7. SIDERITIS *Hiſpanica erecta, folio anguſtiore. Inſt. R. H.* Upright Spaniſh All-heal, with a narrow Leaf.

8. SIDERITIS *Hiſpanica crenata procumbens, flore albo, major. Inſt. R. H.* Greater trailing Spaniſh All-heal, with a white Flower.

9. SIDERITIS *Hiſpanica bituminoſa anguſtifolia crenata. Inſt. R. H.* Spaniſh All-heal, with a bituminous Scent, and a narrow crenated Leaf.

10. SIDERITIS *Hiſpanica fœtidiſſima glabra, flore purpuraſcente, & comâ caneſcente. Inſt. R. H.* Spaniſh ſtinking ſmooth All-heal, with a purpliſh Flower, and whitiſh Tops.

11. SIDERITIS *Hiſpanica fruteſcens, ſeu lignoſior. Inſt. R. H.* Shrubby or more woody Spaniſh All-heal.

12. SIDERITIS *Pyrenaica hyſſopifolia minima procumbens. Inſt. R. H.* The leaſt trailing hyſſop-leafed All-heal of the Pyrenees.

13. SIDERITIS *montana, trifido folio. Barrel. Icon.* Mountain All-heal, with a trifid Leaf.

14. SIDERITIS *Cretica maxima, ocymaſtri Valentini facie, Tourn. Cor.* The greateſt All-heal of Candy, with the Face of *Ocymaſtrum Valentinum.*

15. SIDERITIS *Cretica tomentoſa candidiſſima, flore luteo. Tourn. Cor.* The whiteſt Woolly All-heal of Candy, with a yellow Flower.

There are ſeveral of theſe Plants which are preſerved in ſome curious Botanick Gardens for Variety; but as they are Plants of little Beauty, ſo they are ſeldom cultivated in other Gardens.

All theſe Plants may be propagated by ſowing their Seeds in the *Spring*, upon a Bed of freſh light Earth; and when the Plants are come up, they may be tranſplanted out into other Beds, allowing them a Foot Diſtance from each other, obſerving to water them until they have taken Root; after which they will require no farther Care, but to keep them clear from Weeds; the ſecond Year they will produce Flowers and Seeds, and ſome of the Sorts will periſh ſoon after, but others will abide ſeveral Years, provided they are not planted in a Soil too moiſt.

The fourth Sort grows plentifully by the Sides of Ditches, and in other moiſt Places, in divers Parts of *England*, ſo is very rarely introduced in Gardens, becauſe it is a very bad Weed, wherever it once gets Place; for the Roots creep very far under Ground, and will ſoon over-run a large Spot of Ground, if they are not confined. This Plant received the Name of *Clowns All-heal* from Mr. *Gerard*, who was looking for Herbs in *Kent*, where he ſaw a Man who had cut his Leg to the Bone with a Scyth, as he was mowing the Graſs, to whom he offered his Aſſiſtance to cure his Wound; which the Countryman churliſhly refuſing, crept to the Ditch-ſide, where there was Plenty of this Plant growing; ſome of which he gathered and bruiſed, and apply'd it to the Wound, tying it cloſe with his Handkerchief, which in few Days healed the Wound, without any other Application; for which Reaſon *Gerard* has recorded the Story in his Herbal, for the Benefit of Mankind.

The fifth Sort is alſo a Native of *England*, and grows amongſt the Corn, or other Crops, on arable Land. This is an annual Plant, which periſhes ſoon after it has ripened Seeds.

The other Sorts are moſt of them biennial Plants, which commonly perfect their Seeds the ſecond *Summer*, and ſeldom continue much longer. Theſe may be all propagated by Seeds, which ſhould be ſown in *Autumn*, ſoon after they are ripe; for when they are kept out of the Ground till *Spring*, they very often fail. Theſe Seeds ſhould be ſown on a Bed of freſh undunged Earth, in an open Situation; and when the Plants come up, they ſhould be thinned where they grow too cloſe; and if they are kept clear from Weeds, it is all the Culture they require. If, when theſe Plants are eſtabliſhed in a Garden, their Seeds are permitted to ſcatter, the Plants will come up, and maintain their Place, provided they are not overborn by large Weeds.

All the Sorts of *All-heal* are ſuppoſed to have an aſtringent Quality, and are accounted good to heal Wounds, and may be apply'd either inwardly or outwardly.

SILAUM, Meadow-Saxifrage.

The *Characters* are;

It hath a roſe and umbellated Flower, conſiſting of ſeveral Leaves, placed circularly, and reſting upon the Empalement, which afterward becomes a Fruit compoſed of two ſhort channelled Seeds: To which Notes muſt be added, that the Leaves are very narrow, and the Flowers are of a pale yellow Colour.

The *Species* are;

1. SILAUM *quibuſdam, flore luteolo. J. B.* Common Meadow-ſaxifrage.

2. SILAUM *quod Liguſticum, ferulæ folio. Inſt. R. H. Boerh. Ind. alt.* Saxifrage with the Leaf of Giant Fennel.

3. SILAUM *quod Liguſticum Creticum, folio fœniculi, caule nodoſo. Tourn. Cor. Boerh. Ind.* Candy Meadow-ſaxifrage, with a Fennel Leaf, and a knobby Stalk.

4. SILAUM *quod Liguſticum, cicutæ folio, glabrum. Tourn. Boerh. Ind. alt.* Meadow-ſaxifrage, with a ſmooth Hemlock Leaf.

The firſt Sort is directed by the *College of Phyſicians* to be uſed in Medicine: This grows wild in Meadows, and other moiſt Paſtures, in divers Parts of *England*; but the other Sorts are not Natives of this Country, ſo are only to be met with in Botanick Gardens, where they are preſerved for the ſake of Variety.

All theſe Sorts are propagated by Seeds, which may be ſown in *Autumn* on a Border of freſh Earth in a ſhady Situation; and when the Plants are come up, they will require no farther Care, but to keep them clear from Weeds, and, where they grow too cloſe, to thin them, ſo as to leave them about eight or ten Inches aſunder, which may be done by houghing of them in the ſame Manner as is practiſed for Carrots. Theſe Plants will flower and ſeed the ſecond *Summer*, and the Roots of the three firſt Sorts will abide ſome Years; but the fourth Sort commonly periſhes ſoon after it has produced Seed.

SILER, Seſeli, *or* Sermountain.

The *Characters* are;

It hath a roſe and umbellated Flower, conſiſting of ſeveral Leaves, which are ranged orbicularly, and reſt on the Empalement, which becomes a Fruit compoſed of two large oblong furrowed Seeds, having foliaceous Ridges on one Side: To theſe Notes may be added, that the Lobes of the Leaves are large, long, and intire, excepting their Extremity, where they are ſlightly cut into three Parts.

The *Species* are;

1. SILER *montanum majus. Mor. Umb.* Greater Sermountain.

2. SILER *montanum anguſtifolium. Park.* Narrow-leafed Sermountain.

The firſt Sort is uſed in Medicine by the Direction of the *College of Phyſicians*. The Seeds of this Sort are the *Semen Seſeleos* of the Shops, which enters in Compoſitions; and the green Herb alſo is uſed, for which ſome of the People who ſupply the Shops, often impoſe on their Cuſtomers the *Mountain Oſier*, which, by tranſlating *Siler* an *Oſier*, may afford them ſome Pretence.

The ſecond Sort differs from the firſt, in being ſomewhat leſs, and having narrow Leaves: This is found wild in *Auſtria*, and the former Sort grows on the *Alps* and *Apennines*, and other mountainous Parts of *Italy* and *Spain*.

Theſe Plants may be propagated by Seeds, which ſhould be ſown in *Autumn* (ſoon after they are ripe) on a Border of freſh undunged Earth; and in the *Spring*, when the Plants will appear, they ſhould be kept conſtantly clear from Weeds, and in very dry Weather ſhould be watered, which will greatly promote their Growth. Where the Plants come up too cloſe together, they ſhould be thinned ſo as to leave them three or four Inches apart, which will be ſufficient Room for them the firſt Seaſon; and at *Michaelmas*, when their Leaves decay, ſome of the Plants may be carefully taken up, ſo as not to cut or break their Roots, and tranſplanted into a moiſt ſhady Border, about eighteen Inches aſunder, where they may remain for good. If theſe Plants thrive well, they will produce Seeds the ſecond Seaſon, otherwiſe it will be the third *Summer* before they flower and ſeed; after which the Roots will abide many Years, and increaſe greatly in their Size, and will produce Seeds every Year.

The Culture which theſe Plants require, is only to keep them clear from Weeds, and every *Spring*, juſt before the Plants put out their Leaves, to dig the Ground between them gently, ſo as not to injure their Roots; and when their Flower-ſtems are advanced, to place ſome Stick down by them, to which their Stems ſhould be faſtened with Baſs, to ſupport them from being broken down by Winds; for as theſe Stems riſe to the Height of four or five Feet, ſo when their Umbels of Seeds are formed, which are generally pretty large and heavy, they often occaſion their Stems falling to the Ground, where they are not ſupported.

Theſe Plants flower the latter End of *June*, and their Seeds ripen toward the latter End of *Auguſt*, or the Beginning of *September*.

SILIQUA, Carob *or* St. John's Bread.

The *Characters* are;

It hath an apetalous Flower, having many Stamina, *which grow from the Diviſions of the Flower-cup; in the Centre of which riſes the Pointal, which afterwards becomes a Fruit or Pod, which is plain and fleſhy, containing ſeveral roundiſh plain Seeds.*

We have but one *Species* of this Plant in *England*, viz.

SILIQUA *edulis. C. B. P.* The Carob Tree, *or* St. John's Bread: *vulgo.*

This Tree is very common in *Spain*, and in ſome Parts of *Italy*, as alſo in the *Levant*, where it grows in the Hedges, and produces a great Quantity of long, flat, brown-colour'd Pods, which are thick, mealy, and of a ſweetiſh Taſte. Theſe Pods are many times eaten by the poorer Sort of Inhabitants, when they have a Scarcity of other Food: but they are apt to looſen the Belly, and cauſe Gripings of the Bowels. Theſe Pods are directed by the *College of Phyſicians* to enter ſome medicinal Preparations, for which Purpoſe they are often brought from abroad.

In *England* the Tree is preſerved, by ſuch as delight in exotick Plants, as a Curioſity: The Leaves do always continue green, and being different in Shape from moſt other Plants, afford an agreeable Variety when intermixed with *Oranges*, *Myrtles*, &c. in the Green-houſe.

Theſe Plants are propagated from Seeds, which, when brought over freſh in the Pods, ſhould be ſown in the *Spring* upon a moderate Hot-bed; and when the Plants are come up, they ſhould be carefully tranſplanted, each into a ſeparate ſmall Pot, filled with light rich Earth, and plunged into another moderate Hot-bed, obſerving to water and ſhade them until they have taken Root; after which you muſt let them have Air in Proportion to the Heat of the Weather. In *June* you muſt inure them to the open Air by Degrees, and in *July* they ſhould be removed out of the Hot-bed, and placed in a warm Situation, where they may remain until the Beginning of *October*, when they ſhould be removed into the Green-houſe, placing them where they may have free Air in mild Weather; for they are pretty hardy, and do require only to be ſheltered from hard Froſts. When the Plants have remained in Pots three or four Years, and have gotten Strength, ſome of them may be turned out of the Pots in the *Spring*, and planted into the full Ground, in a warm Situation, where they will endure the Cold of our ordinary *Winters* very well; but muſt have ſome Shelter in very hard Weather.

I have not as yet ſeen any of theſe Trees produce Flowers; tho' from ſome which have been planted ſome time againſt Walls, it is probable there may be Flowers and Fruit in a few Years.

SILIQUASTRUM, the Judas-tree.

The *Characters* are;

It hath a papilionaceous Flower, whoſe Wings are placed above the Standard; the Keel is compoſed of two Petals; the Pointal which riſes in the Centre of the Flower-cup, and is encompaſſed with the Stamina, *afterwards becomes a long flat Pod, containing ſeveral Kidney-ſhaped Seeds: To which may be added, roundiſh Leaves growing alternately on the Branches.*

The *Species* are;

1. SILIQUASTRUM *Caſt. Durant.* The Judas-tree: *vulgo.*
2. SILIQUASTRUM *Canadenſe. Tourn.* Canada Judas-tree.
3. SILIQUASTRUM *quæ Ceratia agreſtis, mucronato folio, floribus parvis, Caroliniana. Pluk. Alm.* Carolina Judas-tree, with pointed Leaves.

The firſt of theſe Trees is very common in the South Parts of *France*, *Italy* and *Spain*, from whence it was formerly brought into *England*, and preſerved as a Curioſity in Green-houſes; but of late Years they have been tranſplanted into the open Air, where they thrive very well, and produce great Quantities of beautiful Flowers in the *Spring*, and in favourable Seaſons do perfect their Seeds extremely well.

The ſecond Sort is very common in *Virginia*, *New-England*, *Canada*, and moſt of the Northern Countries of *America*, where it is called *Red-bud*; which Name, I ſuppoſe, it received from the beautiful Colour of its Flower-buds, which, when fully expanded, are of a ſoft purple Colour. Theſe Flowers are produced in large Cluſters from the old Wood of the Tree; and being opened before the green Leaves come out, they make a beautiful Appearance, eſpecially when the Trees are old, and productive of Flowers; when, many times, the large Branches of the Tree are entirely covered with theſe beautiful Flowers, ſo as to afford as great Pleaſure as any Sort of flowering Tree whatever. Theſe Flowers are commonly gathered in *America*, and put into their Sallets, to which they add a quick poignant agreeable Flavour; and in *England* they are by ſome curious Perſons uſed for the ſame Purpoſe.

The third Sort was brought from *Carolina*, where it grows in the Woods in great Plenty. This differs greatly in the Shape of its Leaves from the other two Sorts, and the Flowers are much ſmaller. At preſent this is leſs common in the *Engliſh* Gardens, and will not endure the Cold of our Climate ſo well, being ſubject to have the young Shoots deſtroy'd in very hard *Winters*; and if the Plants are young, ſometimes they will die to the Ground.

Theſe Plants may be propagated by ſowing their Seed upon a Bed of light Earth, towards the latter End of *March*, or the Beginning of *April*, (and if you put a little hot Dung under the Bed, it will greatly facilitate the Growth of the Seeds;) when your Seeds are ſown, you ſhould ſhift the Earth over them about half an Inch thick; and, if the Seaſon prove wet, it will be proper to cover the Bed with Mats, to preſerve it from great Rains, which will burſt the Seeds, and cauſe them to rot.

When the Plants are come up, they ſhould be carefully clear'd from Weeds, and in very Weather muſt be now and then refreſh'd with Water, which will greatly promote their Growth. The *Winter* following, if the Weather be very cold, it will be proper to ſhelter the Plants, by covering them either with Mats or dry Straw in hard Froſts; but they ſhould conſtantly be open'd in mild Weather, otherwiſe they will grow mouldy, and decay.

About the Beginning of *April* you ſhould prepare a Spot of good freſh Ground, to tranſplant theſe out, (for the beſt Seaſon to remove them is juſt before they begin to ſhoot;) then you ſhould carefully take up the Plants, being careful not to break their Roots, and plant them in the freſh Ground as ſoon as poſſible, becauſe if their Roots are dried by the Air, it will greatly prejudice them.

The Diſtance theſe ſhould be planted muſt be proportionable to the Time they are to remain before they are again tranſplanted; but commonly they are planted two Feet Row from Row, and a Foot aſunder in the Rows, which is full Room enough for them to grow two or three Years, by which Time they ſhould be tranſplanted where they are deſigned to remain; for if they are too old when removed, they ſeldom ſucceed ſo well as younger Plants.

The Ground between the Plants ſhould be carefully kept clean from Weeds in *Summer*, and in the *Spring* ſhould be well dug, to looſen the Earth, that their Roots may better extend themſelves every Way: you ſhould alſo at that Seaſon prune off all ſtrong Side-Branches, (eſpecially if you intend to train them up for Standard Trees) that their Top-Branches may not be chek'd by their Side-Shoots, which do often attract the greateſt Part of the Nouriſhment from the Roots; and if their Stems are crooked, you muſt place a ſtrong Stake down by the Side of each Plant, and faſten the Stem to it in ſeveral Places, ſo as to render it ſtrait, which Direction it will ſoon take as it grows larger, and thereby the Plants will be render'd beautiful.

When they have remain'd in this Nurſery three or four Years, they ſhould be tranſplanted in the *Spring* where they are deſign'd to remain, which may be in Wilderneſs Quarters, among other flowering Trees, obſerving to place them with Trees of the ſame Growth, ſo as they may not be over-hung, which is a great Prejudice to moſt ſorts of Plants.

The uſual Height to which theſe Trees grow with us, is from twelve to twenty Feet, according to the Goodneſs of the Soil; tho' I don't remember ever to ſee any of them exceed that Growth, where they have enjoy'd the greateſt Advantages, nor do I believe the *Carolina* Sort will arrive to near that Height.

SILIQUOUS, having Seed-veſſels, Huſk, Pod or Shell.

SINAPI,

[Σίνηπι, of σίνειν ὀφθαλμοῦς, becauſe it forces Tears from the Eyes of thoſe that uſe it uncautiouſly, makes the Noſe red, and the Eyes ſwell] Muſtard.

The *Characters* are;

The Flower conſiſts of four Leaves, which are placed in form of a Croſs, out of whoſe Flower-cup riſes the Pointal, which afterwards becomes a Fruit or Pod, divided into two Cells by an intermediate Partition, to which the Valves adhere on both Sides, and are fill'd with roundiſh Seeds: theſe Pods generally end in a fungous Horn, containing the like Seeds: to theſe Marks muſt be added, an acrid burning Taſte, peculiar to Muſtard.

The *Species* are;

1. SINAPI *ſiliqua latiuſcula glabra, ſemine ruſo, ſive vulgare. J. B.* Common or Red Muſtard.
2. SINAPI *hortenſe, ſemine albo. C. B. P.* Garden or White Muſtard.
3. SINAPI *Indicum, lactucæ folio. Par. Bat.* Indian Muſtard, with a Lettuce Leaf.

There are ſeveral other *Species* of this Plant, which are preſerv'd in curious Botanick Gardens, for Variety; but as they are not in Uſe, nor have any thing valuable to recommend them, I ſhall not enumerate them here.

The firſt Sort is very common in the *Iſle of Ely* in *Cambridgeſhire*, and in many other Places, where the Land has been flooded with Water for many Years; but upon being drain'd, this Plant comes up in a moſt plenteous Manner, which has given Occaſion for ſome Perſons to imagine that it was produced ſpontaneouſly without Seeds; but the contrary of this has been fully proved by ſeveral learned Gentlemen, and therefore would be needleſs to repeat here; for the Reaſon why theſe Seeds do remain good for ſo many Years, when cover'd with Water, is, becauſe they abound with ſo ſharp an Oil, that it prevents the Water from pervading its Body, and being kept from the Air, is preſerved from Corruption.

This Sort is alſo cultivated in Gardens and Fields, in divers Parts of *England*, for the ſake of its Seeds. The Method of cultivating this Plant, is to ſow the Seeds upon an open Spot of Ground (which hath been well dug or plough'd) in the *Spring*, and when the Plants are come up, they ſhould be hough'd, in order to deſtroy the Weeds, as alſo to cut out the Plants where they are too thick, leaving them about ten Inches aſunder, (for when they are left too thick, they draw up weak, and the Seeds are never ſo large, and well nouriſh'd) and if the Weeds ſhould grow again before the Plants have gotten Strength enough to bear them down, they muſt be hough'd a ſecond time; after which they will require no farther Care until the Seeds are ripe, when the Haulm ſhould be cut down and ſpread upon the Ground to dry, and then the Seeds may be threſh'd out.

The ſecond Sort is chiefly cultivated in Gardens, for a Sallet-Herb in the *Winter* Seaſon. The Seeds of this are commonly ſown very thick in Drills, either upon a warm Border, or in very cold Weather upon a Hot-bed, with *Creſſes*, and other ſmall Sallet-Herbs, which are commonly fit for Uſe in three Weeks or a Month from ſowing; for if they are large, they are too ſtrong to put into Sallets. In order to ſave the Seeds of this Plant, a Spot of Ground muſt be ſown with it in the *Spring*, which ſhould be managed in the ſame Manner as the former.

The third Sort may alſo be uſed in Sallets when it is very young, at which Time it has no diſagreeable Taſte; but as it grows large, ſo its Strength increaſes, and a certain Bitterneſs, which renders it very diſagreeable. This is very hardy, and when allow'd ſufficient Room, will ſpread very far, and produce large Leaves.

The Seeds of the firſt two *Species* are order'd for Medicinal Uſe; but the third is ſeldom cultivated for Uſe in *England*.

SINAPISTRUM, [ſo call'd as tho' *Sinapi parvum, diminutive Muſtard*; becauſe it is like Muſtard in Shape and Acrimony.]

The *Characters* are;

The Flower conſiſts of four Leaves, which are placed in form of a Croſs, but are erected; under theſe Petals are placed ſix Stamina, which occupy the under Part of the Flower; out of whoſe Flower-cup riſes the Pointal, which afterwards becomes a Cylindrical Pod, with two Valves, and fill'd with roundiſh Seeds.

The *Species* are;

1. SINAPISTRUM *Indicum pentaphyllum, flore carneo, minus non ſpinoſum. H. L.* Indian five-leav'd *Sinapiſtrum*, with a Fleſh-colour'd Flower, and not prickly.
2. SINAPISTRUM *Ægyptiacum, heptaphyllum, flore carneo, majus ſpinoſum. H. L.* Greater prickly ſeven-leav'd Egyptian *Sinapiſtrum*, with a Fleſh-colour'd Flower.
3. SINAPISTRUM *Zeylanicum triphyllum & pentaphyllum viſcoſum, flore flavo. Boerh.* Three and five-leav'd viſcous *Sinapiſtrum* from *Ceylon*, with a yellow Flower.

The firſt and ſecond Sorts are very common in *Jamaica*, *Barbadoes*, and other warm Countries in the *Weſt-Indies*; but the third Sort I received from Dr. *Boerhaave*, who had it from *Ceylon*, with many other curious Seeds.

Theſe Plants are preſerv'd as Curioſities by thoſe who delight in Botanick Studies; but as they are not very beautiful, nor of any great Uſe, ſo they are rarely cultivated in other Gardens. They are all annual Plants, which periſh ſoon after their Seeds are ripe; and in *England* muſt be raiſed in a Hot-bed in the *Spring*, and when the Plants have acquired Strength, they ſhould be planted into Pots, and managed as hath been directed for the *Female Balſamines*, to which Article the Reader is deſired to turn, to avoid Repetition. In *July* theſe Plants may be placed in the open Air, at which Time they will flower, and in *September* their Seeds will ripen, when they ſhould be gather'd, and preſerved in their Pods until the Seaſon for ſowing them.

SISARUM, [ſo call'd on account of its ſweet Taſte, ſcarce any Plant being of a ſweeter] Skirret.

The *Characters* are;

It produces its Flowers in an Umbel, which conſiſt of ſeveral Leaves placed circularly, and expand in form of a Roſe; the Empalement afterwards becomes a Fruit, compoſed of two narrow Seeds, that are gibbous and furrow'd on one Side, but plain on the other: to theſe Marks muſt be added, that the Roots are ſhaped like long Turnips, and are join'd to one Head.

We have but one *Species* of this Plant, *viz.*

SISARUM *Germanorum. C. B. P.* Skirret.

This is one of the wholſomeſt and moſt nouriſhing Roots that is cultivated in Gardens, and yet it is at preſent very rare to meet with it in the Gardens near *London*: What may have been the Cauſe of its not being more commonly cultivated, I can't imagine, ſince there are many Kitchen-Gardens which are proper for this Plant.

It may be propagated two Ways, *viz.* either by ſowing the Seeds, or planting the Slips. The former Method is what I would chiefly recommend; becauſe the Roots which come from Seeds, are much larger than thoſe produced from Off-ſets, and are much tenderer. The Seaſon for ſowing the Seed is in the Beginning of *February*, and upon a moiſt rich Soil, which ſhould be well dug and looſen'd, and being laid level, the Seeds ſhould be ſown thereon, and then trod in, after the common Method of ſowing *Radiſhes*, raking the Ground over them ſmooth.

In *April* the Plants will come up, at which Time the Ground ſhould be hough'd over, (as is practiſed for *Carrots*) to deſtroy the Weeds, and to cut out the Plants where they are too cloſe, leaving them the firſt houghing about three Inches aſunder; but at the ſecond houghing, which ſhould be perform'd about a Month after the firſt, they ſhould be cut out to ſix Inches apart at leaſt, obſerving to cut down all the Weeds; and during the *Summer* Seaſon, the Weeds ſhould be diligently hough'd down as faſt as they are produced; for if theſe Plants are ſtifled by Weeds, *&c.* they ſeldom come to good.

When their Leaves are decay'd, their Roots may be taken up for Uſe; but this ſhould be done only as they are wanted; for if they are kept long above Ground, they will be good for little. The Leaves commonly decay in *October*; ſo that from that Time till the Middle of *March*, when they begin to ſhoot again, they are in Seaſon; but after they have ſhot forth green Leaves, the Roots become ſticky, and are not ſo good.

The Method of propagating this Plant from Off-ſets, is as follows: About the latter End of *February*, or Beginning of *March*, you ſhould dig a moiſt rich Spot of Ground, in Size proportionable to the Quantity of Plants intended; then you ſhould carefully dig up the old Roots, from which you ſhould ſlip off all the Off-ſets, preſerving their Buds on the Crown of each intire; after this you ſhould open a Drill croſs the Spot of Ground with a Spade, in a ſtrait Line, about eight or nine Inches deep, into which you ſhould place the Off-ſets, about ſix Inches apart, as upright as poſſible; then fill the Drill up again with the Earth which came out of it, and at a Foot Diſtance from the firſt make another Trench, laying the Off-ſets therein, as before, and ſo continue the Drills at a Foot Diſtance, thro' the whole Spot of Ground; and if the Seaſon ſhould prove very dry, it will be proper to water them until they have taken Root in the Ground; after which they will require no other Care, but to keep the Weeds conſtantly deſtroy'd as they are produced, in the Manner before directed for the ſeedling Plants, and when their Leaves decay, they will be fit for Uſe, as before; but after any of theſe Roots have ſeeded, they are ſticky, and good for nothing; ſo that they ſhould never be more than one Year old.

SISYMBRIUM, Water-creſſes.

The *Characters* are;

It hath a Flower compoſed of four Leaves, which are placed in form of a Croſs, out of whoſe Empalement riſes the Pointal, which afterward becomes a Fruit or Pod, which is divided into two Cells by an intermediate Partition, to which the

Valves adhere on both Sides, and furniſhed with Seeds which are roundiſh. To theſe Marks muſt be added, That the whole Appearance of the Plants is peculiar to the Species of this Genius.

The *Species* are;

1. SISYMBRIUM *aquaticum. Matth.* Common Water-creſſes.

2. SISYMBRIUM *aquaticum, foliis minoribus, præcocius. Raii Syn.* Early flowering Water-creſſes, with ſmaller Leaves.

3. SISYMBRIUM *aquaticum, raphani folio, ſiliquâ breviori. Inſt. R. H.* Water-radiſh.

4. SISYMBRIUM *aquaticum, foliis in profundas lacinias diviſis, ſiliquâ breviori. Inſt. R. H.* Water-radiſh, with deeply jagged Leaves.

5. SISYMBRIUM *paluſtre repens, naſturtii folio. Inſt. R. H.* Water-rocket.

6. SISYMBRIUM *paluſtre minus, ſiliquâ aſperâ. Inſt. R. H.* The leſſer Marſh-rocket, with a rough Pod.

7. SISYMBRIUM *erucæ folio glabro, flore luteo. Inſt. R. H.* Common Winter-creſs.

8. SISYMBRIUM *erucæ folio glabro, flore pleno. Inſt. R. H.* Winter-creſs, with a double Flower.

9. SISYMBRIUM *erucæ folio glabro, minus & præcocius. Inſt. R. H.* Small early-flowering Winter-rocket.

10. SISYMBRIUM *erucæ folio, aſpero, flore luteo. Inſt. R. H.* Winter-creſs, with a rough rocket Leaf, and a yellow Flower.

The firſt and ſecond Sorts of Water-creſſes grow promiſcuouſly in ſtanding Waters in moſt Parts of *England*, and are indifferently gathered for Uſe. Theſe Plants have of late Years been generally uſed as Sallet-herbs in the *Spring* of the Year, and are by many People preferred to all other Sorts of Sallets for the agreeable warm bitter Taſte, and being accounted an excellent Remedy for the Scurvy, and to cleanſe the Blood, as alſo a good Diuretic, they have greatly obtained with moſt People. Theſe are generally gathered in the Ditches, and in other ſtanding Waters near *London*, to ſupply the Markets; but whoever hath a mind to cultivate them, may eaſily do it by taking ſome of the Plants from the Places of their natural Growth, early in the *Spring*, being careful to preſerve their Roots as intire as poſſible, and plant them into Mud, and then let the Water in upon them by Degrees. When they have taken Root, they will ſoon flouriſh and ſpread over a large Compaſs of Water: They ſhould not be cut the firſt Seaſon, but ſuffered to run to Seed, which will fall into the Water, and furniſh a ſufficient Supply of Plants afterward.

But where the Water is ſo deep, that it will not be eaſy to plant theſe Plants, the beſt Method will be to get a Quantity of the Plants, juſt as their Seeds are ripening, and throw them on the Surface of the Water, where they are deſigned to grow; and their Seeds will ripen, and fall to the Bottom, where they will take Root, and produce a Supply of the Plants. Theſe Plants produce Seed the latter End of *June*, or the Beginning of *July*, which is the proper Time for this Work.

The third, fourth, fifth and ſixth Sorts are Water-plants, which grow in ſtanding Waters; ſo are not admitted into Gardens, except for the ſake of Variety.

The ſeventh and ninth Sorts grow wild on dry Banks in ſeveral Parts of *England*: Theſe were formerly uſed as a *Winter* Sallet; but ſince there has been a great Number of other Herbs introduced into the *Engliſh* Gardens, they have been entirely rejected. Theſe may be propagated by Seeds, which ſhould be ſown ſoon after they are ripe; and when the Plants are come up, they ſhould be houghed, to ſeparate them where they are too cloſe, as alſo to deſtroy the Weeds, which is all the Culture they require. The *Summer* following they will produce Seed, and the Plants periſh ſoon after. But if the Seeds are permitted to ſcatter, the Plants will come up, and become troubleſome Weeds.

The eighth Sort is a Variety of the ſeventh, which accidentally aroſe from Seeds, and is preſerved in ſome curious Gardens, for having a double Flower. This is propagated by parting of the Roots, ſo that in order to preſerve this Kind, the Plants ſhould not be ſuffered to ſend forth too many Flower-ſtems, leſt they ſhould exhauſt the Root too much to ſend forth any Side-heads for parting. The beſt Time to tranſplant and part theſe Roots, is at *Michaelmas*, when they ſhould be planted into a Bed or Border of freſh undunged Earth, in an open Expoſure.

The tenth Sort is very like the ſeventh, from which it differs in having a rough Leaf, ſo may be cultivated in the ſame Manner; tho' theſe are rarely allowed a Place in any Gardens, unleſs for the ſake of Variety.

SISYRINCHIUM, Spaniſh Nut.

The *Characters* are;

It hath a Flower reſembling the IRIS, *from which it differs in having a double Root, one lying over the other, after the ſame Manner as thoſe of the* CROCUS *and* GLADIOLUS.

The *Species* are;

1. SISYRINCHIUM *majus, flore luteâ maculâ notato. C. B. P.* Greater Spaniſh Nut, with a Flower marked with a yellow Spot.

2. SISYRINCHIUM *majus, flore albâ maculâ notato. C. B. P.* Greater Spaniſh Nut, with a Flower marked with a white Spot.

3. SISYRINCHIUM *medium. C. B. P.* Middle Spaniſh Nut.

4. SISYRINCHIUM *Creticum montanum, anguſtiſſimo folio. Tourn. Cor.* Mountain Siſyrinchium of Candy, with a very narrow Leaf.

5. SISYRINCHIUM *Africanum, foliis longiſſimis, flore albo, radice venenatâ.* African Siſyrinchium, with very long Leaves, a white Flower, and a poiſonous Root.

The three firſt Sorts grow wild in *Portugal* and *Spain*, where the Roots are ſought after, and dug up by Children and the Shepherds, who eat them, as alſo the Hogs; for they are ſweet, and in Taſte reſemble the Earth-nut. The fourth Sort was diſcovered in the Iſland of *Crete* by Dr. *Tournefort*, who ſent it to the Royal Garden at *Paris*.

Theſe Plants are preſerved by the Curious for their Flowers, which make a fine Appearance when they are in Beauty, which is commonly in *May*, or the Beginning of *June*, about the ſame Time with the *Bulbous Iris*. The Flowers come out alternately from their Sheaths or Coverings, after the Manner of the *Iris*; ſo that there is ſeldom more than one Flower open upon each Stalk at one time; but they ſucceed each other: For there are commonly four or five Flowers produced on each Stalk, when the Roots are ſtrong. Theſe Flowers are in ſome of a fine blue Colour, ſpotted with yellow; and in other Sorts they are of a pale purple Colour, ſpotted with white.

The four firſt Sorts are hardy Plants, which are multiplied by Off-ſets, and may be treated in the ſame Manner as the *Bulbous Iris*, to which the Reader is deſired to turn, where there are full Directions exhibited, both for the propagating them by Off-ſets and Seeds, with which Management theſe Flowers may be cultivated.

The fifth Sort was brought from *Africa*, where the Inhabitants uſe the Root to fuddle the Fiſh in the Rivers, in order to catch them in plenty. The green Leaves of this Sort are poiſonous; for as a Tub of theſe Plants, which were bringing to *England*, was placed on the Deck of the Ship, ſome Hogs getting to it eat down all the Leaves; which ſwelled two of the Hogs, and killed them.

This Plant, being a Native of a warm Country, is too tender to live in this Climate, unleſs it is preſerved in a good Stove; ſo the Roots ſhould be planted into Pots filled with light rich Earth, and plunged into the Bark-bed in the Stove, where if it is preſerved in a kindly Warmth, the Roots will multiply greatly. The Leaves of this Sort die away in *Winter*, and new ones ariſe in the *Spring*; ſo the beſt Time to tranſplant the Roots is juſt before they put out new Leaves, which is commonly in the Beginning of *April*; at which Time the Bark-bed ſhould be ſtirred up and renewed with ſome freſh Tan, and the Pots muſt be plunged again, and frequently refreſhed with Water in warm Weather, which will make them grow very vigorous; but during the *Winter* Seaſon, while the Leaves are decayed, they muſt not have much Wet, leſt it rot the Roots.

SIUM, Water Parſnip.

The *Characters* are;

It hath a Roſe-ſhaped umbellated Flower, conſiſting of ſeveral Petals, which are commonly equal, and placed orbicularly, reſting upon the Empalement, which afterward becomes a roundiſh Fruit, compoſed of two Seeds, which are gibbous and furrowed on one Side, but plain on the other: To theſe Notes muſt be added, that the Leaves are joined together, and adhere to the Rib, with an odd Lobe at the End.

The *Species* are;

1. SIUM *ſive Apium paluſtre, foliis oblongis. C. B. P.* Water Parſnip, with oblong Leaves.

2. SIUM *umbellatum repens. Ger. Emac.* Creeping Water Parſnip.

3. SIUM *latifolium. C. B. P.* Broad-leafed Water Parſnip.

4. SIUM *paluſtre alterum, foliis ſerratis. Inſt. R. H.* Another Water Parſnip, with ſawed Leaves.

5. SIUM *foliorum conjugationibus laciniatis. Inſt. R. H.* Water Parſnip, with the Wings of the Leaves jagged.

6. SIUM *aquaticum, ad alas floridum. Mor. Umb.* Water Parſnip, with Flowers growing at the Wings of the Leaves.

7. SIUM *minimum umbellatum, foliis variis. Pluk. Alm.* The leaſt Water Parſnip, with variable Leaves.

8. SIUM *alterum, oluſatri facie. Lob. Icon.* Long-leafed Water Hemlock.

9. SIUM *arvenſe, ſive ſegetum. Inſt. R. H.* Corn-parſley, *or* Honewort.

10. SIUM *aromaticum, Siſon officinarum. Inſt. R. H.* Stone-parſley, *or* German Amomum.

The firſt, ſecond, third, ſeventh and eighth Sorts, grow pretty common in Ditches, Ponds, and other ſtanding Waters, in divers Parts of *England*; ſo are not cultivated, becauſe they will not live on dry Ground. The ſecond Sort is directed to be uſed in Medicine by the College of Phyſicians, and is eſteemed very good in ſcrophulous Caſes. The firſt Sort is by ſome People miſtaken for *Water-creſſes*, and is ſometimes gathered as ſuch and eaten, though they are very different Plants.

The eighth Sort is a very poiſonous Plant, which was by Dr. *Wepſer* taken for the *Hemlock* of the Ancients; who has written a large Treatiſe of this Plant, in which he has mentioned a Number of Inſtances of the noxious Quality thereof: So that this Plant ſhould be extirpated from Places near Habitations, to prevent any Miſchief which may happen by Perſons uſing of it thro' Ignorance.

The fourth, fifth and ſixth Sorts grow in ſtanding Waters in *France*, *Germany*, and ſome other Parts of *Europe*, but are not Natives of this Country. Theſe are ſometimes preſerv'd in Botanick Gardens for Variety-ſake, but are not uſed in Medicine.

The ninth and tenth Sorts grow on dry Banks, and under Hedges, in ſeveral Parts of *England*, ſo are rarely cultivated in Gardens. The ninth Sort has been by ſome Writers greatly eſteemed for diſcuſſing hard Swellings of the Face, which by ſome Country People are called *Hones*, ſo the Name of *Honewort* was given to this Plant, on account of that Quality. The Seeds of the tenth Sort are uſed in Medicine, as one of the leſſer warm Seeds. This is called *Amomum* by the *Germans*, tho' it is not what the Antients meant by that Name.

All theſe Sorts may be cultivated by Seeds, which ſhould be ſown in the *Autumn* ſoon after they are ripe: Thoſe Sorts which grow in ſtanding Waters, muſt be ſcattered into ſuch Places; but the other Sorts may be ſown on a ſhady Border, where the Plants will come up in the *Spring*, and require no farther Care, but to keep them clear from Weeds, and, where they grow too cloſe together, to thin them, ſo as to allow them Room to grow. The ſecond Year theſe Plants will produce Flowers and Seeds, ſoon after which the Roots will periſh.

SMALLAGE: *vide* Apium.

SMILAX, [ſo called of σμάω, Gr. *to ſcrape*, becauſe it is a rough Plant] Bindweed.

The *Characters* are;

The Flower conſiſts of ſeveral Leaves, which are placed circularly, and expand in form of a Roſe, whoſe Pointal afterwards becomes a Fruit, or ſoft roundiſh Berry, containing oval-ſhaped Seeds.

The *Species* are;

1. SMILAX *aſpera fructu rubente. C. B. P.* Rough Bindweed, with a red Fruit.

2. SMILAX *viticulis aſperis, foliis longis anguſtis, mucronatis, lævibus auriculis ad baſim rotundioribus. Pluk. Phyt.* Rough Bindweed, with long narrow-pointed ſmooth Leaves: having round Ears at the Baſe.

3. SMILAX *viticulis aſperis, Virginiana, folio hederaceo lævi, Zarza nobiliſſima nobis. Pluk. Phyt.* Rough Virginian Bindweed, with a ſmooth Ivy Leaf, commonly called *Zarzaparilla*.

4. SMILAX *Orientalis, ſarmentis aculeatis, altiſſimas arbores ſcandentibus, foliis non ſpinoſis. Tourn. Cor.* Eaſtern Rough Bindweed, with prickly Shoots and ſmooth Leaves.

5. SMILAX *lævis, lauri folio, baccis nigris. Cateſb. Hiſt. Nat. Carol.* Smooth Bindweed, with a Bay Leaf and black Berries.

6. SMILAX *non ſpinoſa humilis, folio ariſtolochiæ baccis rubris. Cateſb. Hiſt. Nat. Carol.* Dwarf ſmooth Bindweed, with a Birthwort Leaf and red Berries.

7. SMILAX *bryoniæ nigræ foliis, caule ſpinoſo, baccis nigris. Cateſb. Hiſt. Nat. Carol.* Bindweed with black briony Leaves, a prickly Stalk and black Berries.

8. SMILAX *Caroliniana, ſtipite quadrato leni, foliis anguſtis aſperis, auriculis ad baſim anguloſis. Pluk. Phyt.* Carolina Bindweed, with ſquare ſmooth Shoots, and rough narrow Leaves, which have cornered Ears at their Baſe.

9. SMILAX *foliis latis, in margine ſpinoſis, Caroliniana ſtipite leni quadrato. Pluk. Phyt.* Carolina Bindweed, with broad Leaves, having Spines on their Edges, and a ſmooth ſquare Shoot.

10. SMILAX *aſpera Bermudenſis, grandioribus foliis cordiformibus, radice ſurculoſâ. Pluk. Phyt.* Rough Bindweed of Bermudas, with larger heart-ſhaped Leaves, and a Root full of Shoots.

11. SMILAX *claviculata, Hederæ folio, tota levis, è Terrâ mariana. Pluk. Phyt.* Smooth Bindweed, with Tendrils, and an Ivy Leaf from Maryland.

12. SMILAX *viticulis aſperis, Virginiana, foliis anguſtis lævibus, nullis auriculis prædita. Pluk. Phyt.* Virginian Bindweed, with rough Shoots and ſmooth narrow Leaves, having no Ears.

13. SMILAX *Virginiana, ſpinus innocuis armata, latis Canellæ foliis. radice arundinaceâ craſſâ & carnoſâ. Pluk. Phyt.* Virginian Bindweed, armed with innocent Spines, broad Cinnamon Leaves, and a thick fleſhy Root, called *Baſtard China*.

14. SMILAX *Americana lævis, Canellæ foliis, baccis rubris.* Smooth American Bindweed, with Cinnamon Leaves and red Berries.

15. SMILAX *aſpera, Americana, Ariſtolochiæ foliis longioribus, ad baſim auriculatis.* Rough American Bindweed, with longer Birthwort Leaves, with Ears at their Baſe, whoſe Root is the *Zarza Parilla* of the Shops.

16. SMILAX *Americana levis, Tamni folio, claviculis longioribus donatis.* Smooth American Bindweed, with a black briony Leaf, ſending forth long Tendrils.

17. SMILAX *Americana, levis, latiſſimo folio, auriculis ad baſim rotundioribus.* Smooth American Bindweed, with a very broad Leaf, having round Ears at the Baſe.

18. SMILAX *unifolia, humillima. Inſt. R. H.* The loweſt Bindweed or one Blade.

12. SMILAX *aſpera racemoſa, polygonati folio. Inſt. R. H.* Rough branching Bindweed, with a Solomons-ſeal Leaf.

20. SMILAX *ſpicata, Polygonati folio. Inſt. R. H.* Spiked Bindweed, with a Solomons-ſeal Leaf.

Moſt of the *Species* of this Plant grow wild in *Virginia*, *Carolina*, and other Parts of *America*, in the Woods, where they climb round the Stems of Trees and Shrubs, to ſupport themſelves; for their Branches are very weak and trailing, and if not ſupported do lie upon the Ground.

Theſe Plants are preſerved in the Gardens of ſuch as are curious in Botany, for their Variety; but there is no great Beauty or Uſe in them; ſo that they are not very commonly cultivated in other Gardens.

They are moſt of them hardy enough to endure the Cold of our Climate, if planted in a light Soil, and under the Shelter of Trees, where they delight to grow. They may be eaſily propagated by Off-ſets, taken from the old Roots in *March*, juſt before they begin to ſhoot, and tranſplanted where they are to remain; where, if it be in a good Soil they will flower very well; but they ſeldom produce Fruit in this Country.

But as the Seeds are often brought into *England*, ſo they may be ſown in Pots of light rich Earth, and placed in a ſhady Situation in *Summer*; but in *Winter* they muſt be removed into Shelter, obſerving always to keep the Earth moiſt, and the following *Spring* the Plants will come up, when the Pots ſhould be again removed into the Shade, and kept clear from Weeds, watering them in dry Weather; and the *Spring* following they may be tranſplanted, where they are to remain.

The fourth Sort here mentioned, was diſcovered by Dr. *Tournefort* in the *Levant*. This is a very rambling Plant, which climbs up Trees, and riſes to a great Height in the Places of its Natural Growth; but is an humbler Plant in this Country. This may be propagated by Seeds, or from Off-ſets taken from the old Roots, and is hardy enough to live in the open Air in this Country, provided it is planted ed under Trees, where it may be a little protected in *Winter*.

The fifth, ſixth, ſeventh, eighth, ninth, tenth, eleventh, twelfth and thirteenth Sorts, are Natives of *Carolina*, *Virginia* and the other northern Parts of *America*, where they grow in the Woods in the greateſt Shade. Theſe may alſo be propagated by Seeds or Off-ſets, from the old Roots as the former. Moſt of theſe Plants are preſerved in Pots in the Gardens of the Curious, but they will endure the Cold of our *Winters* in the open Air very well, and may be rendred ornamental by planting them under Trees in Wilderneſs Quarters, where they will fill up and cover the Ground, and may be diſpoſed ſo as to make an agreeable Variety. Theſe Plants require a Soil rather moiſt than dry ; and if it be tolerably light, they will thrive much better, than in a very ſtrong Soil.

The fourteenth, fifteenth, ſixteenth and ſeventeenth Sorts, are Natives of the warmer Parts of *America*, ſo are more tender than either of the former. Theſe Sorts were diſcovered at *Campechy* by Mr. *Robert Millar* Surgeon, who ſent Samples of them to *England* ; the Root of the fifteenth Sort is the *Zarza Parilla*, which is directed by the College of Phyſicians to be uſed in Medicine.

Theſe Sorts are propagated by Seeds or Off-ſets, in the ſame Manner as thoſe before-mentioned, but theſe muſt be preſerved in Pots, and ſheltered in *Winter*, otherwiſe they will not live in this Country. As theſe Plants rarely produce Seeds in *England*, ſo they are commonly increaſed by parting of their Roots ; the beſt Time for doing of this, is in *March*, juſt before they ſend forth new Shoots from their Roots ; for altho' the old Shoots abide and retain their Leaves throughout the Year, yet there are every *Spring* new Shoots ſent forth from their Roots, which come up, like the ſmall Shoots of *Aſparagus*, with a naked Stem, but afterwards they ſend forth ſide Branches, which are beſet with Leaves. Some of theſe Sorts multiply greatly by their creeping Roots, which will extend to a great Diſtance, provided they are not confined ; but when they extend their Roots very far, they ſeldom produce very ſtrong Shoots, nor do they make ſo good an Appearance, as when they grow cloſe and thick.

When the Seeds of theſe Plants are obtained from abroad, they ſhould be ſown in Pots filled with freſh light Earth, and plunged into a moderate Hot-bed, obſerving to water the Earth frequently to keep it moiſt, becauſe the Seeds being hard, will not vegetate without a conſiderable Share of Moiſture, and many times remain in the Ground a whole Year, before they grow ; ſo that if the Plants do not come up the firſt Seaſon, the Pots ſhould be kept clean from Weeds all the *Summer*, and in *Winter* they ſhould be ſheltered from Froſt under a common Frame ; the following *Spring* they muſt be again plunged into the Hot-bed, which will bring the Plants up very ſoon. When the Plants are come up, they muſt be conſtantly kept clear from Weeds, and frequently watered in warm Weather, and toward the End of *May*, they ſhould be inured to the open Air by degrees, and in *June* they may be removed out of the Bed, and placed abroad in a ſheltered Situation, where they ſhould remain till the Froſt comes on in *Autumn*, when they muſt be removed into ſhelter. Theſe Plants ſhould remain untranſplanted in the Seed-pots, till the following *Spring*, when they ſhould be turned out of the Pots, and carefully ſeparated, the tender Sorts ſhould be planted in Pots filled with freſh Earth ; and if they are plunged into a very temperate Hot-bed, it will cauſe them to take new Root very ſoon, and greatly ſtrengthen the Plants. But the hardy Kinds may be planted abroad under Trees, where (if they are kept clear from Weeds, until they have obtained ſufficient Strength to overbear the Weeds) they will make an agreeable Variety, amongſt other hardy Wood Plants.

The eighteenth, nineteenth and twentieth Sorts, die to the Root every Year, and riſe in the *Spring* ; the fifteenth Sort is a very humble Plant, ſeldom riſing above four Inches high, this increaſes by its creeping Root, for it rarely produces Seeds in this Country. It is a very hardy Plant, and grows in Woods, but it is not a Native of *England*. I obſerved it growing plentifully in a Wood near the *Hague*, in a moiſt light ſandy Soil ; ſo that whoever would cultivate this Plant, ſhould plant it in ſuch Situations. The beſt time to tranſplant this Plant, is in the *Autumn*, when the Leaves are decayed.

The nineteenth and twentieth Sorts ; are alſo propagated by parting of their Roots, which may be done either in the *Autumn*, ſoon after their Leaves decay, or in the *Spring* before they ſend forth new Shoots. Theſe Plants uſually grow between two and three Feet high, and have very much the Appearance of *Solomons-ſeal*, until they produce their Flowers. Theſe Sorts are very hardy, ſo will grow in almoſt any Situation, but ſhould have a freſh light Soil, inclining to Moiſture.

SMYRNIUM, [of Σμύρνια, *Myrrha*, becauſe it reſembles *Myrrh* in Taſte and Smell ; or becauſe that Plant which the Ancients call'd *Smyrnium*, by Inciſion yielded a like Liquid] Alexanders.

The *Characters* are ;

The Flowers are produced in Umbels, conſiſting of ſeveral Leaves, which are placed orbicularly, and expand in form of a Roſe : theſe reſt upon the Empalement, which afterwards becomes an almoſt globular Fruit, compoſed of two pretty thick Seeds, ſometimes ſhaped like a Creſcent, gibbous, and ſtreak'd on one Side, and plain on the other.

The *Species* are ;

1. Smyrnium. *Matth.* Common Alexanders.
2. Smyrnium *peregrinum, rotundo folio. C. B. P.* Foreign Alexanders, with a round Leaf.
3. Smyrnium *peregrinum, folio oblongo. C. B. P.* Foreign Alexanders, with an oblong Leaf.
4. Smyrnium *Creticum, paludapii foliis. T. Cor.* Candy Alexanders, with a Smallage Leaf.

The firſt of theſe Sorts (which is that order'd by the College for Medicinal Uſe) grows wild in divers Parts of *England*, and at preſent is ſeldom cultivated in Gardens ; tho' formerly it was greatly uſed in the Kitchen, before *Celery* was ſo much cultivated, which hath taken Place of *Alexanders*, in moſt Peoples Opinion. The other Sorts are preſerv'd in Botanick Gardens for Variety, but may either of them be cultivated for the Uſe of the Kitchen. The ſecond ſort is much preferable to the firſt for blanching, as I have tried, and will be tenderer, and not quite ſo ſtrong.

All theſe Plants may be propagated by ſowing their Seeds upon an open ſpot of Ground in *Auguſt*, ſo ſoon as they are ripe ; for if they are preſerv'd till *Spring*, they often miſcarry, or at leaſt do not come up until the ſecond Year ; whereas thoſe ſown in *Autumn* do rarely fail of coming up ſoon after *Chriſtmas*, and will make much ſtronger Plants than the other.

In the *Spring* theſe Plants ſhould be hough'd out, ſo as to leave them ten Inches or a Foot apart each Way ; and during the following *Summer* they muſt be conſtantly clear'd from Weeds, which, if permitted to grow amongſt them, will draw them up ſlender, and render them good for little. In *February* following, the Plants will ſhoot up again vigorouſly, at which Time the Earth muſt be drawn up to each Plant, to blanch them ; and in three Weeks after, they will be fit for Uſe, when they may be dug up, and the white Part preſerved, which may be ſtew'd, and eaten as *Celery*.

SNAP-DRAGON : *vide* Antirrhinum.

SNEEZ-WORT : *vide* Ptarmica.

SNOW, is defined to be a Meteor form'd in the middle Region of the Air, of Vapour raiſed by the Action of the Sun, or ſubterraneous Fire, there congeal'd, its Parts conſtipated, its ſpecifick Gravity increaſed, and thus return'd to the Earth in the Form of little *Villi* or Flakes.

The *Snow* we receive may properly enough be aſcribed to the Coldneſs of the Atmoſphere thro' which it falls : When the Atmoſphere is warm enough to diſſolve the *Snow* before it arrives at us, we call it *Rain* ; if it preſerves itſelf undiſſolved, we call it *Snow*.

Snow is very uſeful ; it fructifies the Ground, it guards Corn or other Vegetables from the intenſer Cold of the Air, eſpecially the cold piercing Winds.

It is ſuppoſed to abound with ſalifick and fertile Particles, as much or more than Rain ; however, it is accounted more ponderous, and by that means ſinks deeper into the Ground than Rain does, and therefore is in ſome Caſes of more Benefit to planting ; for which Reaſon, ſome lay Heaps of *Snow* round the Feet of their Foreſt-Trees, eſpecially in hot burning Land.

Monſ. *Le Clerc* ſays, that ſome Parts of a Cloud which ſhould turn into Rain, are ſometimes prevented by the Cold, and form'd into a Conſiſtence which we call *Snow* ; which appears to be form'd of watery Particles, from hence, that when it diſſolves, it turns into Water ; ſo that we may eaſily conceive *Snow* to be made of watery Particles, harden'd by Cold, and gather'd into Flakes, in ſuch a manner as to leave large Interſtices between one another ; which *Snow* is not tranſparent, as the Water, becauſe its more rigid Particles being huddled together by Chance, don't leave ſtrait

Pores between one another, and ſo keep out the Matter of Light.

But when it happens that the Region of the Air under the Cloud is very cold, the Drops of Rain are congeal'd as they fall, and come down in Lumps, which are call'd *Hail*; and theſe Lumps are greater or leſs, according to the Bigneſs of the Rain-Drops of which they are form'd; and theſe Lumps of Hail are alſo variouſly figured.

Dr. *Grew*, in a Diſcourſe of the Nature of *Snow*, obſerves, that many Parts thereof are of a regular Figure, for the moſt part, being, as it were, ſo many little Rowels or Stars of perfect and tranſparent Ice; upon each of which Points are ſet other collateral Points, at the ſame Angles as the main Points themſelves: amongſt theſe there are divers other irregular, which are chiefly broken Points and Fragments of the regular ones; others alſo, by various Winds, ſeem to have been thaw'd, and frozen again into irregular Cluſters, ſo that it ſeems as if the whole Body of *Snow* were one intire Maſs of Iſicles irregularly figured; that is, a Cloud of Vapours being gather'd into Drops, the Drops do forthwith deſcend, and in their Deſcent meeting with a freezing Air, as they paſs thro' a colder Region, each Drop is immediately frozen into an Iſicle, ſhooting itſelf forth into ſeveral Points; but ſtill continuing to deſcend, and meeting with ſome intermitting Gales of warmer Air, or by their being continually wafted to and fro, touching upon one another, ſome are a little thaw'd, blunted, and again frozen into Cluſters, or intangled ſo as to fall again in what we call Flakes; altho' *Snow* is firm Ice, and the Lightneſs of it is owing to the Exceſs of its Surface, in Compariſon to the Matter contain'd in it; as Gold itſelf may be extended in Surface, till it will ride upon the leaſt Breath of Air.

SNOW-DROP: *vide* Narciſſo-Leucojum.

SOIL: *vide* Earth.

SOLANOIDES, Baſtard Nightſhade.

The *Characters* are;

It hath a roſe-ſhaped Flower, conſiſting of five Leaves, whoſe Pointal afterward becomes a roundiſh Fruit, having one hard Seed, which is covered with a thin Pulp, ſo as to have the Appearance of a Berry.

The *Species* are;

1. SOLANOIDES *Americana, Circeæ foliis caneſcentibus. Tourn. American* Solanoides, with hoary Inchanters Nightſhade Leaves.

2. SOLANOIDES *Americana, Circeæ foliis glabris. Tourn. American* Solanoides, with ſmooth Inchanters Nightſhade Leaves.

The firſt Sort was mentioned under the Title of *Phytolacca*, but as Dr. *Tournefort* has eſtabliſhed a new Genus in the Memoirs of the *Academy of Sciences* for theſe two Plants, ſo I have taken the Liberty to place them here under their proper Name.

Theſe Plants are Natives of the warmer Parts of *America*, from whence their Seeds have been brought into *Europe*, and the Plants are now become pretty common in the Gardens of the Curious. They are propagated by Seeds, which ſhould be ſown on a Hot-bed early in the *Spring*; and when the Plants are come up, they ſhould be tranſplanted, each into a ſeparate ſmall Pot, filled with light freſh Earth, and plunged into a moderate Hot-bed of Tanners-bark, obſerving to ſhade them from the Sun, until they have taken new Root, after which Time they muſt have a large Share of Air admitted to them in warm Weather, and they muſt be conſtantly watered; when the Plants have obtained Strength, they ſhould be inured to bear the open Air by degrees, and in *June* they ſhould be ſhifted into larger Pots, and removed either into the Stove, or an airy Glaſs-caſe, where they may have a large ſhare of Air in warm Weather, and if they are duly watered, they will thrive and produce Flowers in *July*, and their Fruit will ripen in *September*; but there will be a Succeſſion of Flowers and Fruit all the *Winter*, provided the Plants are preſerved in a moderate Temperature of Heat; ſo that the Fruit of theſe Plants afford an agreeable Variety in the Stove in *Winter*, for being of a bright red Colour, and growing in long Bunches, they make a fine Appearance. Theſe Plants will abide ſeveral Years, and produce plenty of Flowers and Fruit, but they ſhould conſtantly remain in Shelter, for if they are expoſed in *Summer*, they will loſe their large Leaves, and appear ſtunted, nor will the Fruit continue on the Plants; ſo that the beſt way is, to let them remain always in the Stove, giving them a large ſhare of Air in *Summer*, which will keep them in Vigour, and render them beautiful.

The Fruit of theſe Plants afford a fine red Colour, when bruiſed, but it ſoon fades on Paper, which renders it worth little. If a Quantity of theſe Fruit is ſqueez'd into a Glaſs of fair Water, ſo as to colour the Water, of a deep Red, and a Stem of Flowers of the *Tuberoſe* put into the Glaſs, it will in one Night imbibe ſo much of the Liquor as to variegate the Flowers with a roſe Colour.

SOLANUM, [ſo call'd of *ſolari*, Lat. *to comfort*, becauſe this Plant ſweetens the Humours] Nightſhade.

The *Characters* are;

The Flower conſiſts of one Leaf, which is divided into five Parts, and expands in form of a Star; from the Flower-cup riſes the Pointal, which afterwards becomes a round or oval ſoft ſucculent Fruit, containing many flat Seeds in each.

The *Species* are;

1. SOLANUM *officinarum, acinis nigricantibus. C. B. P.* Common Nightſhade of the Shops, with black Fruit.

2. SOLANUM *officinarum, acinis puniceis. C. B. P.* Nightſhade, with red Fruit.

3. SOLANUM *officinarum, acinis luteis. C. B. P.* Nightſhade, with yellow Fruit.

4. SOLANUM *ſcandens, ſeu dulcamara. C. B. P.* Perennial climbing Nightſhade, *commonly called* Bitter-ſweet.

5. SOLANUM *ſcandens, ſeu dulcamara, flore albo. C. B. P.* Perennial climbing Nightſhade, with a white Flower.

6. SOLANUM *ſcandens, foliis variegatis. H. R. Par.* Perennial climbing Nightſhade, with variegated Leaves.

7. SOLANUM *fruticoſum bacciferum. C. B. P.* Shrubby Berry-bearing Night-ſhade, *commonly called* Amomum Plinii.

8. SOLANUM *Guineenſe, fructu magno inſtar ceraſi nigerrimo umbellato. Boerh. Ind.* Night-ſhade from *Guiney*, with large Fruit, reſembling Black Cherries, which grow in an Umbel.

9. SOLANUM *ſpiniferum fruteſcens, ſpinis igneis, Americanum. Pluk. Phyt.* Shrubby and thorny American Nightſhade, with Fire-colour'd Thorns.

10. SOLANUM *ſpinoſum, maxime tormentoſum. Bocc. Rar. Plant.* Thorny Nightſhade, very much cover'd with a Wooll or Down.

11. SOLANUM *Americanum ſpinoſum, foliis melongenæ, fructu mammoſo. D. Lig. Tourn.* Thorny American Nightſhade, with Leaves like thoſe of Mad-Apple, and a Fruit ſhaped like an inverted Pear, *commonly call'd* in *Barbados* Batchelors-Pear.

12. SOLANUM *pomiferum fruteſcens Africanum ſpinoſum nigricans, flore boraginis, foliis profunde liciniatis. H. L.* Shrubby African Apple-bearing Nightſhade, with black Thorns, a Flower like Borage, and deeply jagged Leaves, *commonly call'*d Pomum Amoris.

13. SOLANUM *tuberoſum eſculentum. C. B. P.* Potatoes.

14. SOLANUM *tuberoſum eſculentum, flore albo. H. R. Par.* White Potatoes.

15. SOLANUM *Americanum ſpinoſum herbaceum, Acanthi folio, flore amplo cæruleo. Houſt.* Prickly herbaceous *American* Nightſhade, with a Bears-breech Leaf, and a large blue Flower.

16. SOLANUM *Americanum ſpinoſiſſimum, herbaceum Anguriæ folio, flore luteo. Houſt.* The moſt prickly *American* Nightſhade, with a Water-melon Leaf, and a yellow Flower.

17. SOLANUM *Americanum fruteſcens, & ſpinoſum, Quercus folio, baccis rubris. Houſt.* Shrubby and prickly *American* Nightſhade, with an Oak Leaf, and red Berries.

18. SOLANUM *Americanum bacciferum, caule & foliis tomento incanis, ſpinoſis flore luteo, fructu croceo. Sloan. Cat.* Berry-bearing *American* Nightſhade, with hoary Stalks and Leaves, a yellow Flower, and Saffron-coloured Fruit.

19. SOLANUM *Americanum fruticoſum, bacciferum ſpinoſum, flore cæruleo. Sloan.* Shrubby Berry-bearing *American* Nightſhade, with a blue Flower.

20. SOLANUM *Americanum, fruteſcens & ſpinoſum, flore magno albo. Houſt.* Prickly and ſhrubby *American* Nightſhade, with a large white Flower.

21. SOLANUM *Americanum, ſcandens, & fruteſcens, flore magno cæruleo, fructu rubro. Houſt.* Shrubby climbing *American* Night-ſhade, with a large blue Flower, and a red Fruit.

22. SOLANUM *Americanum fruteſcens, non ſpinoſum, Lauri folio, flore racemoſo cæruleo. Houſt.* Smooth ſhrubby *American* Nightſhade, with a Bay-leaf and blue Flowers, growing in Cluſters.

23. Solanum *Americanum, fruteſcens & ſpinoſum, foliis infra tomentoſis, flore magno cæruleo. Houſt.* Shrubby and prickly *American* Nightſhade, with Leaves which are hoary underneath, and a large blue Flower.

24. Solanum *Americanum, arboreſcens, Verbaſci folio, fructu flaveſcente majori. Plum.* Tree-like *American* Nightſhade, with a Mullein Leaf, and a larger yellow Fruit.

25. Solanum *Bonarienſe arboreſcens, Papas floribus; Hort. Elth.* Tree-like Nightſhade of *Beunos Ayres*, with Flowers like the Papaw.

26. Solanum *Bahamenſe, arboreſcens, folio ſinuato. Hort. Elth.* Tree-like Nightſhade from the *Bahama Iſlands*, with a ſinuated Leaf.

27. Solanum *lignoſum Africanum, ſempervirens Laurinis foliis. H. Amſt.* Woody ever-green *African* Nightſhade, with Bay Leaves.

28. Solanum *Americanum ſcandens, foliis tomentoſis. Plum.* Climbing *American* Nightſhade, with woolly Leaves.

29. Solanum *Americanum ſcandens, aculeatum, Hyoſcyami folio, flore intus albo extus purpureo. Plum.* Climbing prickly *American* Nightſhade, with a Henbane-leaf, and a Flower white within, and purple on the Outſide.

30. Solanum *Americanum fruticoſum, Perſicæ foliis aculeatum. Plum.* Shrubby and prickly *American* Nightſhade, with Peach-Leaves.

31. Solanum *Dulcamarum Africanum, foliis craſſis hirſutis. Hort. Elth.* Climbing *African* Nightſhade with hairy thick Leaves.

32. Solanum *Americanum arboreſcens, non ſpinoſum, flore parvo rubente, fructu aureo. Houſt.* Smooth *American* Tree-like Nightſhade, with a ſmall reddiſh Flower and a Gold-coloured Fruit.

33. Solanum *Americanum arboreſcens, non ſpinoſum, Lauri folio, aſpero, floribus umbellatis albis. Houſt.* Smooth Tree-like *American* Night-ſhade, with a rough Bay-leaf, and white Flowers growing in Umbels.

The firſt Sort is now very common upon Dunghills, and on rich cultivated Soils, in many Parts of *England*, where it often becomes a troubleſome Weed. This is the Sort which the College of Phyſicians have directed to be uſed in Medicine, under the Title of *Solanum hortenſe*. The ſecond and third Sorts are very near to the firſt, differing from it in the Colour of their Fruits, and the Plants being woolly. The eighth Sort produces much larger Fruit than either of the former, and the Plants grow proportionably larger.

All theſe Sorts are annual Plants, which may be propagated by ſowing their Seeds in *March*, upon a Bed of light rich Earth, in a warm Situation; and when the Plants come up, they ſhould be tranſplanted out into freſh Beds of rich Earth, at about ſix Inches Diſtance, obſerving to water and ſhade them until they have taken Root, as alſo to keep them clear from Weeds, and in very dry Weather they ſhould be often refreſh'd with Water: in theſe Beds they may remain until they have grown ſo large as to meet each other, when they may be taken up, with a good Ball of Earth to each Plant, and planted where they are to remain, obſerving to allow them at leaſt two Feet Diſtance, otherwiſe they will ſpread over each other, or any other Plants which grow near them. This Care may be taken with a few Plants of the red and yellow-berry'd and *Guiney* Sorts, for the ſake of Variety; but the common Sort, if permitted to ſcatter its Seeds, will come up in plenty, without any Care.

The fourth Sort is a climbing woody Plant, which grows in the Hedges in divers Parts of *England*, and is by ſome planted in Gardens, to cover Arbours or ſhady Walls, in *London*, and other cloſe Places, where few other Plants will thrive. This Plant is alſo uſed in Medicine, for ſome particular Preparations; but the Herb-folks in the Markets do often ſell this inſtead of the Garden *Nightſhade*, which is a cooling Plant, and this a hot acrid one, which renders it contrary to the Intention of the Ointment, wherein *Nightſhade* is one of the Ingredients.

The Sort with white Flowers is a Variety of the former, as is alſo that with variegated Leaves, both which are preſerv'd by thoſe who are very curious in collecting the various Kinds of Plants.

Theſe may be eaſily propagated by laying down their Branches, or by planting their Cuttings in the *Spring* upon a moiſt Soil, where they will ſoon take Root, and may afterwards be tranſplanted where they are to remain.

The *Amomum Plinii* is propagated in great plenty, for the Beauty of its large red Fruit, which is always ripe in *Winter*, ſo that when the Trees have plenty of Fruit, they make a very handſome Appearance in a Green-houſe, when intermix'd with *Orange*, *Myrtle*, and other Exotick Trees.

This Plant may be propagated by ſowing its Seeds in a Pot of rich Earth in the *Spring*, placing it upon a moderate Hot-bed, which will greatly facilitate the Growth of the Seeds: the Earth in the Pot ſhould be frequently water'd; for if it is kept too dry, the Seeds will not grow. When the Plants are come up, you ſhould make a gentle Hot-bed, which muſt be cover'd with rich Earth about ſix Inches thick; in this they ſhould be planted about ſix Inches Diſtance each Way, and the Bed arch'd over with Hoops, &c. and cover'd with Mats, to ſhade them from the Sun and Cold, obſerving frequently to water them.

When the Plants have acquired Strength, and the Seaſon becomes favourable, you muſt inure them to bear the open Air by degrees, to which they ſhould be fully expoſed in *June*, when alſo they ſhould be taken up, with a Ball of Earth to the Root of each Plant, and placed ſeparately in Pots fill'd with rich Earth, which muſt be ſet in a ſhady Situation, and frequently water'd until they have taken Root; after which they may be removed into a more open Expoſure, and placed amongſt other Exotick Plants; but they do require a great Plenty of Water in dry Weather, without which they ſeldom produce much Fruit

In *Winter* they muſt be removed into the Green-houſe, and placed in the coldeſt Part of the Houſe, where they may have as much free Air as poſſible in mild Weather, being ſo hardy as many times to endure the Cold of our ordinary *Winters* abroad, when planted in a warm Situation, ſo that they only require to be ſheltered from ſevere Froſt.

Theſe Plants ſhould be annually ſhifted about the latter End of *April*, when their Roots ſhould be pared round, cutting off all the mouldy Fibres which were next the Pot, and the Pots fill'd up with rich Earth, which will ſtrengthen their Flowers, and cauſe them to produce Plenty of Fruit, which (as I ſaid before) ripens in *Winter*, and being of the Shape and Size of Cherries, are commonly call'd *Winter-Cherries* by the Gardeners.

The ninth and eleventh Sorts are much tenderer than the former, being brought from the warm Parts of *America*: Theſe are alſo propagated by ſowing their Seeds in the *Spring* upon a good Hot-bed, and when the Plants are come up, they ſhould be each tranſplanted into a ſeparate ſmall Pot fill'd with rich Earth, and plunged into a freſh Hot-Bed, obſerving to water and ſhade them until they have taken Root; after which they ſhould have Air and Water in proportion to the Heat of the Seaſon, and the Bed in which they are placed; and when their Roots have fill'd the Pots in which they were planted, (which they will do in a Month's time, if they thrive) they muſt be ſhaken out, and after having gently pared off the Fibres which grew next the Pot, they ſhould be placed in Pots a Size larger, which muſt be fill'd with freſh rich Earth, and plung'd into a freſh Hot-bed, to bring the Plants forward, obſerving to water them frequently; for they will not thrive without plenty of Moiſture in warm Weather.

In *July* theſe Plants may be inured to bear the open Air by degrees, into which they may be removed, if the Seaſon be warm; but otherwiſe they muſt always be preſerv'd either under Glaſſes or in the Stove; and if they are placed in the open Air, they ſhould not remain there longer than the Middle of *Auguſt*, leſt the Nights growing cold, ſhould hurt them. During the *Winter* Seaſon they muſt be preſerv'd in the Stove, obſerving to water them frequently, and the ſecond Year they will produce Flowers and Fruit.

The tenth and twelfth Sorts are not ſo tender as the laſt, but require an open airy Glaſs-caſe, or a warm Green-houſe in *Winter*; but in *Summer* may be expoſed in the open Air with other Exotick Plants. Theſe may be propagated by ſowing their Seeds on a Hot-bed, as the former, and ſhould be managed as hath been directed for them, with this Difference, that they may be much ſooner expoſed to Air, and ſhould not be bred ſo tenderly. Theſe are preſerved for their odd Appearance, by ſuch as are curious in cultivating Exotick Plants: their Fruits being ripe in *Winter*, do afford a Variety in the Green-houſe, and their Leaves and Flowers being remarkable in their Colour, Shape, &c. do render them worthy of a Place in every good Collection of Plants.

There is alſo another Variety, which differs very much from the tenth Sort, tho' call'd by that Name in moſt of the *Engliſh* Gardens where it is preſerv'd, which I believe came from *Virginia*, and being ſomewhat like the Figure given by *Pere Boccone* of the tenth Sort, I ſuppoſe was taken for the ſame Plant; but they are very different from each other, as appear'd by ſome Plants which I raiſed from Seeds ſent me by *Signior Tilli*, Profeſſor of Botany at *Piſa*, of *Boccone*'s Plant, and others raiſed from the old Sort which came from *Virginia*, both which being cultivated together, retain'd a ſpecifick Difference.

The Red and White *Potatoes* are both indifferently cultivated in *England*; tho' the red Sort is moſt commonly brought to the Markets. Theſe Plants were originally brought from *Virginia* into *Europe*, where they are at preſent ſo generally eſteem'd, as to be one of the moſt common eſculent Roots now in Uſe.

Theſe Plants are propagated by planting the ſmalleſt Roots in the *Spring*, which, in a good Soil, will multiply exceedingly; for I have many times ſeen ten, twelve, or more Roots produced from a ſingle Off-ſet in one Year.

The Soil on which theſe ſhould be planted, ought to be rather moiſt than dry, and of a rich ſoft looſe Texture; for if the Ground be too dry or binding, they will produce but very ſmall Roots, and thoſe but ſparingly. This Soil ſhould be well dug or plough'd, and the ſmall Roots laid in Trenches or Furrows ſix Inches deep, and about ſix Inches aſunder in the Furrows; but the Furrows muſt be a Foot Diſtance from each other; for when they are too cloſe, their Roots will not be large, which is what People uſually covet.

In the *Spring* and *Summer* Months, the Weeds ſhould be carefully hough'd down between the Plants, until their Haulm is ſtrong enough to bear them down, and prevent their Growth: and when their Haulm decays in *Autumn*, the Roots may be taken up for Uſe; which may be done as they are wanted, till the Froſt begins to ſet in; when there muſt be a Quantity taken up, and laid in Sand in a dry Cellar, where they may be protected from Froſt. The beſt of theſe may be taken out for Uſe in *Winter*, and the ſmall ones reſerved to plant in the *Spring*.

The fifteenth, ſixteenth, ſeventeenth, twentieth, twenty-firſt, twenty-third, thirty-ſecond and thirty-third Sorts, were diſcovered by the late Dr. *Houſtoun*, near *La Vera Cruz*, in *America*, from whence he ſent their Seeds to *England*, many of which have ſucceeded in ſeveral curious Gardens, where the Plants are now growing.

The fifteenth and ſixteenth Sorts are annual Plants, ſo, rarely produce ripe Seeds in *England*; but the others are abiding Plants, which flower every year, and ſometimes they perfect their Fruit in this Country.

Theſe being Natives of a warm Country, muſt be raiſed on a Hot-bed early in the *Spring*, and when the Plants are fit to tranſplant, they muſt be each planted in a ſeparate ſmall Pot filled with freſh rich Earth, and plunged into a moderate Hot-bed of Tanners-bark, obſerving to ſhade them from the Sun until they have taken new Root; after which Time, they ſhould have a large Share of freſh Air admitted to them in warm Weather, and they muſt be plentifully watered. Toward the latter end of *June*, it will be proper to harden the Plants to endure the open Air, and ſoon after they ſhould be removed into the Stove, where they muſt have as much free Air as poſſible in warm Weather; but as the Cold approaches in *Autumn*, they muſt be carefully protected there from, and in *Winter* they ſhould be kept in a moderate Temperature of Warmth, otherwiſe they will not live in this Country.

Some of theſe Sorts will bear to be expoſed in the open Air, in the Heat of *Summer*, provided they are placed in a warm Situation, but if the Seaſon ſhould prove cold, they will not thrive abroad, ſo it will be the better Method to let them remain in the Stove, and open the Glaſſes in Front, and at the Top of the Stove every Day, to admit as much Air as poſſible in hot Weather, with which Management they will thrive much better than in the open Air.

The eighteenth and nineteenth Sorts were diſcovered by Sir *Hans Sloane* in *Jamaica*, where they grow in plenty. The Seeds of theſe were alſo ſent to *England* by the late Dr. *William Houſtoun*.

The twenty-ſecond Sort was diſcovered by the late Dr. *William Houſtoun*, at *Campechy*, where it hath ſince been found in great plenty by Mr. *Robert Millar* a Surgeon, who ſent the Seeds to *England*.

The twenty-fourth, twenty-eighth and twenty-ninth Sorts, were diſcovered by Father *Plumier* in ſome of the *French* Settlements in the *Weſt-Indies*, and have ſince been found by Mr. *Robert Millar*, near *Carthagena* in *America*, from whence he ſent their Seeds.

The twenty-fifth Sort was ſent from *Beunos Ayres*, and the twenty ſixth Sort is a Native of the *Bahama Iſlands*.

All theſe being Natives of warm Countries, muſt be treated in the ſame Manner, as hath been directed for the former Sorts, otherwiſe they will not thrive in *England*.

The twenty-ſeventh and thirty-firſt Sorts are Natives of the *Cape of Good Hope*, ſo are leſs tender than any of the other Kinds. Theſe muſt be preſerved in Pots, and placed in a good Green-houſe in *Winter*, where they ſhould have a large Share of free Air in mild Weather, but muſt be ſecured againſt Froſt, during the *Winter* Seaſon; theſe Plants will require to be frequently refreſhed with Water, but in cold Weather it muſt be given to them in moderate Quantities; and in *Summer* the Plants ſhould be placed in the open Air, in a warm ſheltered Situation, during which Seaſon, they will require a more plentiful Supply of Water in dry Weather, for they are thirſty Plants, as are all of this Tribe.

The climbing Sorts of Nightſhade may be propagated by Cuttings, which ſhould be taken off in *May*, and thoſe of the tender Kinds ſhould be planted in Pots filled with freſh Earth, and plunged into a Hot-bed of Tanners-bark, where they ſhould be carefully ſcreened from the Heat of the Sun every Day, until they have taken Root; after which Time they may be treated in the ſame Manner, as thoſe Plants which come from Seeds. But the thirty-firſt Sort, which is more hardy, will not require ſo much Care; for if the Cuttings of this Kind are planted in a ſhady Border, they will take Root, and may be afterwards taken up and potted, and placed in a warm Situation in the open Air till *October*, when they muſt be removed into the Green-houſe for the *Winter* Seaſon.

Theſe Plants, when they thrive well, and produce plenty of Fruit, make an agreeable Variety amongſt other exotick Plants, in the Stove, and Green-houſe, eſpecially in the *Winter* Seaſon, at which time they commonly have plenty of Fruit, which make a pretty Appearance, when there are not many other Plants in Beauty. And ſome of theſe Sorts, whoſe Flowers are large and of beautiful Colours, make a fine Appearance, and are worthy of a Place in the Stove, tho' they do not conſtantly produce Fruit in this Climate, eſpecially the fifteenth Sort, whoſe Flowers are very large and of a fine blue Colour; and the twenty-ſecond Sort, whoſe Flowers, tho' ſmall, yet being produced in long Cluſters, and being of a fine blue Colour, make a fine Appearance; and theſe do frequently flower in the *Winter* Seaſon.

SOLDANELLA, Soldanel.

The *Characters* are;

It hath a Bell-ſhaped Flower, conſiſting of one Leaf, which is for the moſt part fringed; the Pointal, which ariſes from the lower Part of the Empalement, afterwards becomes a Fruit of a cylindrical Figure, opening at the Top, and full of Seeds, which adhere to a Placenta.

The *Species* are;

1. SOLDANELLA *Alpina rotundifolia. C. B. P.* Round-leav'd Soldanel of the *Alps*.
2. SOLDANELLA *Alpina rotundifolia, flore niveo. C. B. P.* Round-leav'd Soldanel of the *Alps*, with a Snow-white Flower.
3. SOLDANELLA *Alpina, folio minus rotundo. C. B. P.* Soldanel of the *Alps*, with a Leaf leſs round.

Theſe Plants grow on the *Alps*, and ſeveral other mountainous Places of *Italy*, *Germany*, and *Hungary*, from whence the Plants have been obtained by ſome curious Perſons, who preſerve them in their Gardens for the ſake of Variety. They are Plants of humble Growth, ſeldom riſing above ſix or eight Inches high; their round Leaves grow cloſe to the Ground, from between which the Flower Stems ariſe; each of which have four or five Flowers, which in the firſt Sort are of a fine blue Colour, but the ſecond of a Snow-white, which hang down and are ſhaped like Bells. They flower the latter End of *April*, or the Beginning of *May*, and their Seeds are ripe in *July*.

The beſt Method to propagate theſe Plants, is, by parting of their Roots, becauſe their Seeds do not ſucceed unleſs they are perfectly ripe and well nouriſhed, and this rarely happens in *England*; nor do the Seeds which are brought from abroad ſucceed, for they ſeldom grow, unleſs they are ſown ſoon after they are ripe.

The Time for tranſplanting and parting of theſe Roots is in *September*, that they may have Time to make good Roots before *Winter*; for if they are removed in the *Spring*, they never flower very ſtrong, and if the Seaſon ſhould prove dry, the Plants will decay, unleſs they are conſtantly ſupplied with Water.

The Soil in which theſe Plants thrive beſt, is a ſtrong cool Loam, and they muſt have a ſhady Situation, for if they are expoſed to the Sun, they will not live, nor will they thrive in a warm light Soil. In dry Weather theſe Plants ſhould be frequently watered, which will cauſe them to flower ſtrongly, and make a good Increaſe.

If the Seeds ripen in *England*, and any Perſon is deſirous to propagate the Plants that Way, they ſhould be ſown in Boxes or Pots, filled with freſh loamy Earth, ſoon after they are ripe; and the Boxes muſt be placed in a ſhady Situation, and frequently watered in dry Weather. The Plants will ſometimes appear the ſame *Autumn* the Seeds are ſown, but more frequently they do not come up till the following *Spring*, ſo that the Earth muſt not be diſturbed, nor Weeds permitted to grow in the Boxes. When the Plants come up, they muſt be duly watered in dry Weather, and conſtantly placed in a ſhady Situation. The following *Autumn* the Plants ſhould be taken out of the Boxes, and planted in a ſhady Border, about ſix or eight Inches aſunder, where they may remain to flower: or they may be intermixed with other low Alpine Plants in North Borders, where they will make an agreeable Variety.

SOLSTICE, is the Time when the *Sun* is in one of the Solſtitial Points; that is, when he is at his greateſt Diſtance from the *Equator*, which is twenty three Degrees and an half: Thus called, becauſe he then appears to ſtand ſtill, and not to change his Place in the Degrees of the *Zodiack* any Way; an Appearance owing to the Obliquity of our Sphere, and which thoſe who live under the *Equator* are Strangers to.

The *Solſtices* are two in each Year; the *Eſtival* or *Summer Solſtice*, and the *Hyemal* or *Winter Solſtice*.

The *Summer Solſtice* is, when the Sun is in the Tropick of *Cancer*, which is on the 11th of *June*, when he makes our longeſt Day.

The *Winter Solſtice* is, when the Sun enters the firſt Degree of *Capricorn*, which is on the 11th of *December*, when he begins to return toward us, and make our ſhorteſt Day.

This is to be underſtood, as in our Northern Hemiſphere; for in the Southern, the Sun's Entrance into *Capricorn* makes the *Summer Solſtice*, and that into *Cancer* the *Winter Solſtice*.

SONCHUS, Sowthiſtle.

Theſe are moſt of them Weeds in *England*, and are not planted in Gardens; for if their Seeds are once permitted to ſcatter upon the Ground, they will ſoon ſtock it with Plants; for which Reaſon they ſhould always be extirpated, not only thoſe in the Garden, but alſo in the Parts near it, becauſe their Seeds being furniſhed with Down, are wafted in the Air to a conſiderable Diſtance, where falling to the Ground, they ſoon come up and prove troubleſome.

SORBUS, [ſo called of *ſorbere*, Lat. *to ſup*, becauſe the Fruit, being ripe, is ſo ſoft that it may be ſupped] The Service-tree.

The *Characters* are;

The Flower conſiſts of ſeveral Leaves, which are placed orbicularly, and expand in form of a Roſe, *whoſe Flower-cup afterwards becomes a Fruit ſhaped like a* Pear *or* Medlar; *To which muſt be added, pennated Leaves, like thoſe of the* Aſh.

The *Species* are;

1. SORBUS *ſativa. C. B. P.* The manured Service-tree.
2. SORBUS *ſativa, fructu pyriformi, medio rubente. H. Cath.* The manured Service, with Pear-ſhaped Fruit, red in the Middle.
3. SORBUS *ſativa, fructu ſerotino minori turbinato rubente. Tourn.* The leſſer late-ripe Service, with a Medlar-ſhaped Fruit.
4. SORBUS *aucuparea. J. B.* The Wild Service *or* Quick-beam, *by ſome called* The Quicken-tree.
5. SORBUS *ſylveſtris, foliis ex luteo variegatis.* The Wild Service *or* Quick-beam, with ſtriped Leaves.
6. SORBUS *ſativa fructu ovato, medio rubente. Hort. Cath.* The manured Service, with an oval Fruit, which is red within.
7. SORBUS *ſativa, magno fructu turbinato, pallidè rubente. Inſt. R. H.* The manured Service, with a large turbinated Fruit of a pale red Colour.
8. SORBUS *ſativa, magno fructu nonnihil turbinato, rubro. Inſt. R. H.* The manured Service, with a large red Fruit not turbinated.
9. SORBUS *ſativa, fructu turbinato, omnium minimo. Inſt. R. H.* The manured Service, with the leaſt Fruit.
10. SORBUS *Orientalis, Fraxini folio. Tourn. Cor.* Eaſtern Service, with an Aſh Leaf.
11. SORBUS *Orientalis, fructu magno, compreſſo & flaveſcente. Tourn. Cor.* Eaſtern Service, with a large, flat, yellowiſh Fruit.

The manured *Service* was formerly ſaid to be growing wild in *England*; but this I believe was a Miſtake; for ſeveral curious Perſons have ſtrictly ſearched thoſe Places where it was mentioned to grow, and could not find it; nor could they learn from the Inhabitants of thoſe Countries, that any ſuch Tree had grown there.

In *Italy* theſe Trees are very common, where they have a great Variety of Sorts, which were obtained from Seeds; but I have not obſerved in the *Engliſh* Gardens more than the five firſt Sorts, and thoſe are yet very ſcarce; for I have not ſeen more than one large Tree of the true *Service* in *England*, which was lately growing in the Gardens formerly belonging to *John Tradeſcant* at *South Lambeth*, near *Vauxhall* in *Surrey*, who was a very curious Collector of rare Plants in King *Charles the Second*'s Time; which Tree was near forty Feet high, and did produce a great Quantity of Fruit annually. There are, indeed, ſome Trees of middling Growth in the Gardens of *Henry Marſh*, Eſq; at *Hammerſmith*, which produce Fruit, (from whence ſeveral young Plants have been raiſed of late in the Nurſeries near *London*) but theſe are ſmall, when compared to that in *John Tradeſcant*'s Garden.

Theſe Fruits do nearly reſemble *Medlars* in their Nature, being of a very auſtere Taſte, till they are rotten, when they have a more agreeable Flavour: But in *England* their Fruit does not ripen ſo well as in warmer Countries, and is therefore leſs eſteemed: However, the Trees are propagated by ſuch Perſons as are curious in collecting the various Kinds of hardy Trees and Shrubs, for the Oddneſs of their Leaves and Fruit.

They may be propagated by ſowing their Seeds on a moderate Hot-bed in the *Spring*; and when the Plants are come up, they ſhould be carefully kept clear from Weeds, and in dry Weather watered; but they ſhould be expoſed to the open Air: For the only Reaſon of making a Hot-bed, is to forward the Growth of the Seeds; but if when the Plants are come up, the Bed is covered, it will draw the Plants, and ſpoil them. In this Bed the Plants ſhould remain until the Middle of *March* the ſucceeding *Spring*, when there ſhould be a warm light Spot of Ground prepared to receive them; into which they ſhould be planted in Rows two Feet aſunder, and a Foot diſtant in the Rows; obſerving to take them up carefully, and to plant them as ſoon as poſſible, that their Roots may not dry.

During the *Summer*, the Ground ſhould be kept conſtantly clear from Weeds, and in *Winter* there ſhould be a little Mulch laid upon the Surface of the Ground about their Roots, to protect them from being injured by Froſt; but in the *Spring* the Ground between them ſhould be dug, burying the Mulch therein: In doing of which, you muſt be careful not to cut or injure the Roots of the Plants.

In this Nurſery they may continue three or four Years, according to their Growth, when it will be proper to tranſplant them out where they are to remain: The beſt Seaſon for which is in *March*, juſt before they begin to ſhoot. The Soil ſhould be warm in which they are planted, and the Situation defended from cold Winds: In which Place they will thrive, and produce Fruit in a few Years; but as the Fruit will vary from thoſe which the Seeds were taken from, (as is the Caſe of moſt Sorts of Fruit) ſo the ſureſt Method to have the particular Sorts which you intend to cultivate, is to bud or graft them either upon their own or the Wild *Service* Stock; upon which they will take and produce Fruit in a few Years.

The Wild *Service* or *Quick-beam* grows wild in divers Parts of *England*; but it is often cultivated in Gardens, for Variety. This produces large Bunches of Flowers at the Extremity of its Branches in *May*, which are ſucceeded by large roundiſh Fruit, which change to a beautiful ſcarlet Colour in *Autumn*, when they afford an agreeable Variety in Wilderneſs Quarters.

This Tree ſeldom grows above twenty Feet high, ſo ſhould be always placed in Lines of Trees of the ſame Growth.

The Wood of this Tree is much commended by the *Wheelwright* for being all Heart; and it is of great Uſe for *Huſbandmens* Tools, Goads, *&c.* The Flowers of this Tree ſmell very ſweet, and the Fruit is extraordinary Food for *Thruſhes*, ſo that where theſe Trees are planted they will greatly frequent.

The Sort with variegated Leaves is preſerved by ſuch as are curious in collecting the ſeveral Sorts of ſtriped Plants; but there is no great Beauty in it. This may be propagated by Layers, or by being budded on the plain Sort; but they will become plain again, if planted on a very rich Soil.

Theſe Trees ſhould have a moiſt ſtrong Soil, but will grow in the moſt expoſed Places, being extremely hardy, which renders them worthy of Care, ſince they will thrive where few other Trees will ſucceed.

The ſixth, ſeventh, eighth and ninth Sorts are very common in the *Italian* Gardens, and of late Years they have been brought into *England*, by the Perſons who bring over Orange Trees, *&c.* ſo that in a few Years, they may be common in *England*. But the great Difficulty is in keeping of the Sorts; becauſe when theſe Trees are propagated by Seed, they vary as much in their Kinds as do *Apples* and *Pears*. And it is very difficult to propagate them by grafting or budding; for they ſeldom ſucceed when grafted on *Pears*, *Apples*, or *Medlars*, and it is not eaſy to raiſe Stocks of their own Kind, for the Fruit do not always ripen in this Country.

The tenth and eleventh Sorts were diſcovered by Dr. *Tournefort* in the *Levant*, but at preſent they are not in the *Engliſh* Gardens. Theſe Sorts may be all propagated by Seeds, after the manner above directed. The beſt Way to procure good Seeds of theſe Plants, is to have the Fruit, when duly ripened abroad, put up in Boxes of Sand and ſent over, in which Method they may be brought over very well; for if the Fruit ſhould rot, the Seeds will remain good by being preſerved in Sand.

SORREL: *vide* Acetoſa.

SOUTHERNWOOD: *vide* Abrotanum.

SOWBREAD: *vide* Cyclamen.

SPARTIUM, [ſo called of *Sparum*, a *Dart*, becauſe the Ruſhes of this Plant repreſent a Dart; or elſe of the *Greek* σπάρτον, of σπείρεσθαι, *to ſow*, becauſe it ſows itſelf. It is alſo called *Monoſpermum*, of μόνος, *ſingle*, and σπέρμα, *Seed*, becauſe the Fruit of this Plant contains but one ſingle Seed] The Broom-tree.

The *Characters* are;

It hath a papilionaceous Flower, whoſe Pointal, which riſes from the Flower-cup, afterwards becomes a ſhort, roundiſh, ſwelling Pod, containing, for the moſt part, one Kidney-ſhaped Seed in each.

The *Species* are;

1. SPARTIUM *alterum monoſpermum, ſemine reni ſimile. C. B. P.* Another Spaniſh Broom, with Pods containing one Kidney-ſhaped Seed.
2. SPARTIUM *tertium, flore albo. C. B. P.* The white Spaniſh Broom.
3. SPARTIUM *Orientale, humile fructu villoſo & roſtrato. Tourn. Cor.* Dwarf Eaſtern Broom, with a hairy-beaked Fruit.
4. SPARTIUM *Orientale, ſiliquâ compreſſâ, glabrâ & annulata. Tourn. Cor.* Eaſtern Broom, with a flat, ſmooth, circular Pod.
5. SPARTIUM *Americanum, portulacæ foliis aculeatum, Ebeni materie. Plum.* Prickly American Broom, with Purſlain Leaves, whoſe Wood is taken for Ebony.
6. SPARTIUM *Americanum ſcandens, Citri foliis, floribus albis, ad nodos confertim naſcentibus. Plum.* Climbing American Broom, with Citron Leaves and white Flowers, which are produced in Bunches at the Joints.

The firſt and ſecond of theſe Plants are propagated by ſowing their Seeds upon a moderate Hot-bed in the *Spring*; and when they are come up, they muſt be each planted in a ſeparate ſmall Pot, filled with freſh, light Earth, and plunged into a freſh Hot-bed, obſerving to water and ſhade them until they have taken Root; after which they muſt have a good Share of free Air, by raiſing the Glaſſes when the Weather is favourable; and when the Plants begin to have Strength, they muſt be inured to the open Air by Degrees: Into which they ſhould be removed in *July*, placing them in a warm Situation, and during the *Summer* Seaſon, they muſt be frequently watered; and the Beginning of *October* they muſt be removed into the Green-houſe, placing them where they may have Air and Sun, and as the Earth of the Pots dries, they muſt be refreſhed with Water.

The *Spring* following they ſhould be ſhaken out of the ſmall Pots, and put into others a Size larger, filling them up with freſh, light Earth; and as the Seaſon advances, ſo they muſt be inured to the open Air again; and in *May* they ſhould be carry'd abroad, and placed amongſt other exotick Plants, where they will add to the Variety.

While theſe Plants are young, they are ſomewhat tender; but when they are woody, they will endure a greater Degree of Cold; and if planted in a very warm Situation, will endure the Cold of our ordinary *Winters* in the open Air.

The Flowers of theſe Plants are ſmall, and generally produced thinly upon the Branches, ſo that they do not make a very great Appearance; however, for Variety, they may have a Place in every good Collection of Plants. The ſort with white Flowers will often produce ripe Seeds in *England*, when the *Summer* is warm; but the Seeds of both ſorts may eaſily be obtained from *Spain* or *Portugal*, where they grow wild in great Plenty.

The third and fourth Sorts were diſcovered by Dr. *Tournefort* in the *Levant*, from whence he ſent the Seeds to the *Royal Garden* at *Paris*. Theſe Plants are as hardy as the two firſt mentioned, and ſhould be propagated and managed in the ſame Manner.

The fifth Sort is very common in *Jamaica*, and ſeveral other Places in the *Weſt-Indies*, where the Wood is cut and ſent to *England*, under the title of *Ebony*, tho' it is not the true black *Ebony*, which is a Native of the Eaſtern Country, and is a Plant of a very different Genus. The Wood of this *American Ebony* is of a fine greeniſh-brown Colour, and poliſhes very well, ſo is much coveted by the Inſtrument-makers, and is uſed for ſeveral Purpoſes, being of a very hard durable Nature.

The ſixth Sort is pretty common in the *Spaniſh Weſt-Indies*, from whence I have received the Seeds, which were collected by Mr. *Robert Millar*. This is a climbing Plant, which will twiſt round whatever Trees grow near it, and will riſe to a great Height. The Leaves of this Plant are thick and ſtrong, ſomewhat reſembling thoſe of the Citron Tree, and continuing green the whole Year, they make an agreeable able Variety in the Stove, amongſt other tender exotick Plants.

The four laſt Plants are propagated by Seeds, which muſt be procured from the Countries of their natural Growth, for they do not produce Seeds in this Climate; theſe Seeds ſhould be ſown in Pots filled with light freſh Earth, early in the *Spring*, and plunged into a good Hot-bed of Tanners-bark, where they ſhould be frequently refreſhed with Water, and if the Nights ſhould prove cold, the Glaſſes of the Hot-bed ſhould be covered with Mats, to keep the Bed in a good Temperature of Warmth: In the Middle of the Day, when the Sun ſhines warm, the Glaſſes ſhould be raiſed to let the Steam of the Bed paſs off, as alſo to admit freſh Air. In about a Month after the Seeds are ſown the Plants will appear, when they muſt be carefully treated (being very tender while young); they muſt have freſh Air admitted to them every Day, when the Weather is warm, and ſhould be frequently refreſhed with Water, when the Earth in the Pots appears dry. In about five or ſix Weeks after the Plants appear they will be fit to tranſplant, when they ſhould be carefully ſhaken out of the Pots, and ſeparated, planting each into a ſmall Pot filled with light rich Earth, and then plunge them into the Hot-bed again, being careful to ſhade them from the Sun every Day, until they have taken new Root; after which Time they muſt be treated in the ſame Manner as other very tender exotick Plants, by giving them Air every Day in warm Weather, and watering them every other Day gently, and when the Nights are cold to cover the Glaſſes. In this Hot-bed the Plants may remain till *Autumn*, when they muſt be removed into the Stove, and plunged into the Bark-bed: Thoſe of them whoſe Roots have filled the Pots, ſhould be carefully ſhifted into Pots one Size larger, before they are plunged; but as theſe Plants are not of quick Growth while young, ſo they do not require to be often ſhifted out of the Pots. During the *Winter* Seaſon theſe Plants muſt be kept very warm (eſpecially the firſt Year) and they muſt be frequently refreſhed with Water, but in cold Weather it muſt be given to them in ſmall Quantities, and if their Leaves ſhould contract Filth, they muſt be waſhed with a Sponge to clean them, otherwiſe the Plants will not thrive. As theſe Plants are very tender, ſo they will not live in the open Air in this Country, even in the warmeſt Part of the Year, therefore they muſt be conſtantly kept in the Stove, and ſhould be plunged in the Bark-bed; obſerving in the *Summer* Seaſon, when the Weather is warm, to admit a large Share of freſh Air to the Plants, but in *Winter* they muſt be kept very warm. With this Management the Plants will thrive very well, and in a few Years will produce their Flowers, when they will make a pretty Appearance in the Stove.

SPERGULA, Spurrey.

The *Characters* are;

It hath a Roſe-ſhaped Flower, conſiſting of five Leaves, which are included in a five-leafed Empalement; in the Centre of the Flower ariſes the Pointal, which afterward becomes a roundiſh membranaceous Fruit, which opens in three Parts, and is filled with ſmall Seeds, which in ſome Species have a Border round them.

The *Species* are;

1. SPERGULA. *J. B.* The common Spurrey.
2. SPERGULA *marina noſtras. J. B.* The Sea Spurrey.
3. SPERGULA *purpurea. J. B.* Purple Spurrey.
4. SPERGULA *minima, ſeminibus marginatis.* The leaſt Spurrey, with bordered Seeds.

Theſe Plants grow wild in ſeveral Parts of *England*. The ſecond Sort is found on the Sea Shores where the ſalt Water uſually flows, but the other Sorts grow on ſandy Commons, and amongſt Corn in great Plenty.

The firſt Sort is cultivated in *Holland* and *Flanders*, for feeding their Cattle; the uſual Time of ſowing the Seed is in *Auguſt*, that the Plants may have Time to get Strength before the *Winter*'s Cold. The Uſe that is made of this Graſs, is to feed Sheep and other Cattle in *Winter*, when the common Graſs hath done growing. This Plant ſeldom riſes above ſix Inches high, ſo will not afford a very great Quantity of Food; but as it will grow on the pooreſt Sand, ſo it may be cultivated in many Places to good Advantage, where no other Graſs will thrive ſo well; and by feeding it off the Ground, the Dung of the Cattle will improve the Land. This Paſture, 'tis affirmed, will make excellent Butter, and the Mutton fed on it, is ſaid to be well taſted, ſo is by many preferred to that fed on Turneps. Hens will greedily eat this Herb, and it makes them lay more Eggs.

This Plant being annual, muſt be ſown every Year, and whoever is willing to ſave the Seeds, ſhould ſow it in *April*, that the Plants may flower the Beginning of *July*, and the Seeds will ripen in *Auguſt*, when it muſt be cut before the Heads are quite brown, otherwiſe the Seeds will ſoon ſcatter.

The Seeds being very ſmall, about twelve Pounds will be ſufficient to ſow an Acre of Land. The Ground ſhould be well dreſſed before the Seeds are ſown, for if the larger Clods are not broken, there will be an uneven Crop of Graſs: People in the low Country ſow this Seed, after a Crop of Corn is taken off the Land. The fourth Sort is now much cultivated in *Flanders*, though it is a much lower Plant than the common Sort, but they eſteem it a much better Graſs. The Seeds of this Kind are ſmaller and flatter than thoſe of the common Sort, and have a white Border round each.

SPHONDYLIUM, Cow-parſnep.

The *Characters* are;

It is an umbelliferous Plant, with a Roſe-ſhaped Flower, conſiſting of five uneven Heart-ſhaped Leaves, which are placed circularly, and reſt on the Empalement; which afterward becomes a Fruit, compoſed of two large Seeds, which are flat and oval, having a Point that wants a Border within, channelled, and generally caſting off their Cover, and marked with dark Spots in the Part where they adhere to each other.

The *Species* are;

1. SPHONDYLIUM *vulgare hirſutum. C. B. P.* Common hairy Cow-parſnep.
2. SPHONDYLIUM *vulgare hirſutum, floribus purpureis. C. B. P.* Common hairy Cow-parſnep, with purple Flowers.
3. SPHONDYLIUM *majus, ſive panax Herculeum quibuſdam. J. B.* Greater Cow-parſnep, *or* Hercules's All-heal.
4. SPHONDYLIUM *criſpum. J. B.* Curled Cow-parſnep.
5. SPHONDYLIUM *hirſutum, foliis anguſtioribus. C. B. P.* Hairy Cow-parſnep, with narrower Leaves.
6. SPHONDYLIUM *foliis anguſtioribus, atro-purpureis. H. R. Monſp.* Cow-parſnep, with narrower dark purple Leaves.
7. SPHONDYLIUM *Alpinum parvum. C. B. P.* Small Cow-parſnep of the *Alps*.
8. SPHONDYLIUM *Alpinum glabrum. C. B. P.* Smooth Cow-parſnep of the *Alps*.
9. SPHONDYLIUM *Orientale maximum. Tourn. Cor.* Greateſt Eaſtern Cow-parſnep.
10. SPHONDYLIUM *Orientale ampliſſimo folio, caule brevi. Tourn. Cor.* Eaſtern Cow-parſnep, with a very large Leaf, and a ſhort Stalk.
11. SPHONDYLIUM *Orientale, longiſſimo & anguſtiſſimo folio. Tourn. Cor.* Eaſtern Cow-parſnep, with a very long and very narrow Leaf.
12. SPHONDYLIUM *Orientale, anguſtifolium glabrum, aniſum olens. Tourn. Cor.* Smooth narrow-leafed Eaſtern Cow-parſnep, ſmelling like *Aniſe*.
13. SPHONDYLIUM *Orientale, foliis ammi perennis. Tourn. Cor.* Eaſtern Cow-parſnep, with perennial Biſhops-weed Leaves.
14. SPHONDYLIUM *Orientale humilius, foliis abſinthii. Tourn. Cor.* Dwarf Eaſtern Cow-parſnep, with Wormwood Leaves.
15. SPHONDYLIUM *Orientale, Dauci vulgaris folio, aſphodeli radice. Tourn. Cor.* Eaſtern Cow-parſnep, with a common Carrot Leaf, and an Aſphodel Root.

The firſt and fifth Sorts grow wild in *England*; the firſt is very common on the Sides of Ditches, and the Borders of Fields, in moiſt Land every where. The other Sorts are not Natives of this Country, but are many of them preſerved in Botanick Gardens, for the ſake of Variety.

They are all very hardy Plants, which may be propagated by Seeds; the beſt Time for ſowing them is in *Autumn*, ſoon after the Seeds are ripe. They ſhould be ſown where the Plants are deſigned to remain, becauſe they ſend forth tap Roots, ſomewhat like thoſe of the Parſnep, ſo do not thrive ſo well when tranſplanted, as if ſuffered to remain where they are ſown. The Plants grow very large, ſo the Seeds ſhould be ſown in Drills, at two Feet and a half Diſtance, and in the *Spring*, when the Plants appear, they ſhould be thinned, ſo as to leave them at leaſt eighteen Inches aſunder in the Rows; after which they will require no farther Care, but to keep them clear from Weeds; and when the Plants have obtained Strength, they will not eaſily be injured by Weeds, for they will overbear them, and prevent their getting up. The ſecond Year theſe Plants will produce Flowers and Seeds, and their Roots will abide many Years, and produce Seeds every Year, which if permitted to ſcatter, will fill the neighbouring Ground, and become troubleſome Weeds.

The third Sort (which is very common in *Germany*) hath been by ſome of the *German* Writers taken for the *Acanthus*, or Bears-breech, and the ſame Qualities applied to it.

The Name of *Cow-Parſnep* was given to this Plant, from the Cows eating of it, but they do not chuſe to eat the Leaves of this Plant, if they can get any other Food, as may be obſerved in the Fields where the Plant is in great Plenty; for the Cows will eat the Graſs very cloſe about theſe Plants, though they are rarely found to be touched by them, unleſs when the Graſs is burnt up. Rabbits will eat the Leaves of this Plant, and ſeem fond of it.

SPINA ALBA, *vide* Meſpilus.

SPINACHIA; Spinach *or* Spinage.

The *Characters* are:

It hath an apetalous Flower, conſiſting of many Stamina *included in the Flower-cup, which are produc'd in Spikes upon the Male Plants which are barren; but the* Embryo's *are produc'd from the Wings of the Leaves on the Female Plants, which afterwards becomes a roundiſh or angular Seed, which in ſome Sorts have Thorns adhering to them.*

The *Species* are;

1. SPINACHIA *vulgaris, capſula ſeminis aculeata. Tourn.* The common prickly *or* narrow-leav'd *Spinach*.
2. SPINACHIA *vulgaris, capſula ſeminis non aculeata. Tourn.* Common ſmooth-ſeeded *Spinach*, with broader Leaves.
3. SPINACHIA *vulgaris, capſula ſeminis non aculeata, folio maximo rotundo. Spinach*, with ſmooth Seeds, and a very large round Leaf.

The firſt of theſe Sorts is commonly cultivated in Gardens for *Winter* Uſe, it being much hardier than any of the other Sorts.

The Seeds of this Kind ſhould be ſown upon an open ſpot of Ground towards the latter End of *July*, obſerving, if poſſible, to do it when there is an Appearance of Rain; for if the Seaſon ſhould prove dry for a long time after the Seed is ſown, the Plants will not come up regularly, and many times there will not be half a Crop. When the *Spinach* is come up, the Ground ſhould be houghed to deſtroy the Weeds, and alſo to cut up the Plants where they are too cloſe, leaving the remaining Plants about four or five Inches aſunder: But this ſhould always be done in dry Weather, that the Weeds may be deſtroy'd after they are cut.

About a Month or five Weeks after the firſt Houghing, the Weeds will begin to grow again, therefore the Ground ſhould be then houghed again the ſecond Time, obſerving as before, to do it in dry Weather: But if the Seaſon ſhould prove moiſt, it will be proper to gather the Weeds up after they are cut, and carry 'em off the Ground; for if the *Spinach* is not clean'd before *Winter* from Weeds, they will grow up, and ſtifle it ſo that in wet Weather the *Spinach* will rot away.

In *October* the *Spinach* will be fit for Uſe, when you ſhould only crop off the largeſt Leaves, leaving thoſe in the Centre of the Plants to grow bigger; and thus you may continue croping it all the *Winter* and *Spring*, until the young *Spinach* ſowed in the *Spring*, is large enough for Uſe, which is commonly in *April*; at which time the *Spring* advancing, the *Winter Spinach* will run up to Seed, ſo that you ſhould cut it up, leaving only a ſmall Parcel to produce Seeds.

But the Ground in which this *Winter Spinach* is ſown, being commonly planted with early *Cabbages*, it is not proper to let any of the *Spinach* remain there for Seed, but it ſhould be cleared off as ſoon as ever the *Spinach* is fit for Uſe. that the *Cabbages* may be earth'd up, and laid clear, which is of great Service to them; therefore you ſhould ſow a ſmall Spot of Ground with this Sort of *Spinach* on Purpoſe to ſtand for Seed, where there ſhould be no other Plants among it.

The two Sorts with ſmooth Seeds do produce much larger and thicker round Leaves than the former, but being ſomewhat tenderer, are always ſown in the *Spring*, eſpecially the third Sort, which is preferable to either of the former for *Summer* Uſe.

Theſe are either ſown upon an open Spot of Ground by themſelves, or elſe mix'd with *Radiſh-ſeed*, as is the common Practice of the *London* Gardeners, who always endeavour to have as many Crops from their Land in a Seaſon as poſſible: But, where Land is cheap in the Country, it will be the better Method to ſow it alone without any other Sort of Seed mix'd with it; and when the Plants are come up, the Ground ſhould be houghed to deſtroy the Weeds, and cut out the Plants where they are too cloſe, leaving the remaining about three Inches aſunder; and when they are grown ſo large as to meet, you may then cut out a Part of it to uſe, thinning them, that they may have Room to ſpread; and this Thinning may be twice perform'd, as there is Occaſion for the *Spinach*, at the laſt of which the Roots ſhould be left eight or ten Inches aſunder; and if then you hough the Ground over again, to deſtroy the Weeds, it will be of great Service to the *Spinach*; for if the Land is good upon which it was ſown, the third Sort, with this Management, will many times produce Leaves as large as the Broad-leav'd Dock, and be extremely fine.

But in order to have a Succeſſion of *Spinach* through the Seaſon, it will be proper to ſow the Seed at three different Times in the *Spring*; the firſt early in *January*, which muſt be on a dry Soil; the ſecond the Beginning of *February*, upon a moiſter Soil; and the third the Beginning of *March*, which ſhould be on a very moiſt Soil; and this third Sowing ſhould be houghed out thinner the firſt Time of houghing it, than either of the former Sowings; for there will be no Neceſſity to leave it for cutting out thin for uſe, becauſe the former Sowings will be ſufficient to ſupply the Table 'till this third Sowing is full grown; beſides, by leaving it thin at firſt, it will not be apt to run up to Seed ſo ſoon as it would if the Plants were cloſe.

In order to ſave Seed of either of theſe Kinds, you ſhould ſow an open rich Spot of Ground, with the Sort you intend, in *February*, after the Danger of being injur'd by Froſt is over; and when the Plants are come up, they ſhould be houghed out to ſix or eight Inches Diſtance, obſerving to cut down the Weeds at the ſame Time; and when the Plants have grown about three Weeks or a Month longer, they ſhould be houghed a ſecond Time, when they ſhould be left twelve or fourteen Inches aſunder at leaſt; for when they have ſhot out their Side-branches, they will ſufficiently ſpread over the Ground.

You muſt alſo obſerve to keep 'em clear from Weeds, which if ſuffer'd to grow amongſt the *Spinach*, will cauſe it to run up weak, and greatly injure it. When the Plants have run up to Flower, you will eaſily perceive two Sorts amongſt them, *viz.* *Male* and *Female*; the *Male* will produce Spikes of ſtamineous Flowers, which contain the *Farina*, and are abſolutely neceſſary to impregnate the Embryo's of the *Female* Plants, in order to render the Seeds prolifick. Theſe *Male* Plants are by the Gardeners commonly called *She Spinach*, and are often by the Ignorant pulled up as ſoon as they can be diſtinguiſhed from the *Female*, in order, as they pretend, to give Room for the Seed-bearing to ſpread; but from ſeveral Experiments which I made on theſe Plants, I find, where-ever the *Male* Plants are intirely removed before the *Farina* is ſhed over the *Female* Plants, the Seed will not grow which they produce, ſo that it is abſolutely neceſſary to leave a few of them in every Part of the Spot; though there may be a great many drawn out where they are too thick; for a ſmall Quantity of *Male* Plants (if rightly ſituated) will be ſufficient to impregnate a great Number of *Female*, becauſe they greatly abound with the *Farina*, which, when ripe, will ſpread to a conſiderable Diſtance, when the Plants are ſhaken by the Wind.

SPIRÆA FRUTEX, [ſo called of σπεῖρα, a *Rope*, becauſe this Shrub is flexible like a Rope] Spiræa Frutex, *vulgo*.

The *Characters* are;

The Flower is compoſed of many Leaves, which are plac'd in a circular Order, and expand in form of a Roſe; out of whoſe Flower-cup riſes the Pointal, which afterwards becomes a Fruit compoſed of ſeveral Pods, in which are contain'd ſeveral oblong Seeds.

The *Species* are;

1. SPIRÆA *ſalicis folio. Tourn.* Spiræa Frutex, *vulgo.*
2. SPIRÆA *opuli folio. Tourn.* Spiræa with a Marſh-Elder Leaf, *commonly call'd* Virginian Gelder-Roſe with a Currant Leaf.
3. SPIRÆA *Hyperici folio non crenato. Tourn.* Hypericum Frutex, *vulgo.*
4. SPIRÆA *Africana odorata, foliis piloſis. Com. Rar.* Sweet-ſcented African Spiræa with hairy Leaves.
5. SPIRÆA *Hiſpanica, Hyperici folio crenato. Inſt. R. H.* *Spaniſh* Spiræa, with a notched St. Johns-wort Leaf, commonly called Hypericum frutex, with a notched Leaf.

The firſt of theſe Shrubs is very common in the Nurſeries near *London*, where it is ſold with other flowering Shrubs at a certain Price by the Hundred. This Shrub ſeldom riſes above five Feet high, ſo is proper to intermix with other Shrubs of the ſame Growth, in ſmall Wilderneſs Quarters, and other Plantations of flowering Trees.

This Plant may be propagated from Suckers, which are ſent forth in Plenty from the Stems of the old Plants, or by laying down the tender Branches, which, when rooted, ſhould be tranſplanted out in Rows at three Feet diſtance, and the Plants a Foot aſunder in the Rows: In this Nurſery they may remain two Years, obſerving to keep the Ground clear from Weeds, and in the *Spring* to dig up the Ground between the Rows, ſo that their Roots may the more eaſily extend themſelves; and if they ſhoot out many Side-branches, they ſhould be prun'd off, ſo as to reduce the Shrubs to a regular Figure, and afterwards they may be tranſplanted where they are to remain, either in ſmall Wilderneſs Quarters, or in Clumps of flowering Shrubs, obſerving to place them amongſt other Sorts of equal Growth.

The ſecond ſort is not quite ſo common in *England* as the former. This was originally brought from *America*, but it being full as hardy as the former, and increaſing as faſt by Suckers, it may ſoon be obtain'd in Plenty. This is nearly of the ſame Growth with the former, and may be intermixed therewith in Wilderneſs Quarters, to add to the Variety; it may be propagated and manag'd in the ſame Manner as the former.

The third Sort is very common in the Nurſeries near *London*, where it is generally known by the Name of *Hypericum Frutex*, and is ſold amongſt other flowering Shrubs at a common Rate. This may be propagated by laying down the under Branches, which will take Root in the Compaſs of one Year, when they may be taken off, and planted in a Nurſery for two or three Years (as hath been directed for the former) after which they may be tranſplanted out where they are deſign'd to remain, placing 'em with the two former, being nearly of the ſame Growth, where they will add to the Variety.

The two firſt Sorts do produce their Flowers at the Extremity of their Shoots, the firſt in a long Spike, and the ſecond in Form of an Umbel, but the third ſort produces its Flowers at the Joints of the former Year's Wood, in Bunches, ſo that the whole Tree ſeems covered with white Flowers, when they are blown. They all three produce their Flowers in *May*, and ſometimes continue in Beauty 'till *June*, in a cool Seaſon, for which they are eſteemed by the Curious.

Theſe Shrubs do require no other Pruning but to cut out all the dead Branches, and ſuch as grow irregular, and take off all their Suckers every Year, for if theſe are permitted to grow, they will ſtarve the old Plants, by drawing away their Nouriſhment. The Ground between 'em ſhould alſo be dug every *Spring*, to encourage their Roots, and every third Year a little rotten Dung buried therein, which will cauſe 'em to flower very ſtrong.

The fourth ſort is a Native of the *Cape of Good Hope*, where the Inhabitants call it *Buchu*, and eſteem it extremely for many medicinal Purpoſes, but particularly for expelling the Venom of Snakes.

This Plant is at preſent very rare in *England*, and I believe in moſt Parts of *Europe*, though formerly it was growing in ſeveral curious Gardens in *Holland*, but hath been loſt in that Country for ſome Time, 'till two Years ago it was retrieved again from the *Cape of Good Hope*, by Mr. *George Clifford* of *Amſterdam*, a Gentleman who is extremely curious in Botany and Gardening, from whom I was furniſh'd with it.

This Plant is propagated from Seeds, which ſhould be ſown upon a moderate Hot-bed in the *Spring*, and when the Plants are come up, they muſt be tranſplanted each into a ſeparate ſmall Pot, fill'd with light, freſh Earth, and plung'd into a freſh Hot-bed, obſerving to water 'em, and ſhade the Glaſſes in the Heat of the Day until they have taken Root, after which they ſhould have Air in proportion to the Heat of the Weather, and the Bed in which they are placed. In *June* they ſhould be inured to the open Air by Degrees, and the Beginning of *July* they ſhould be remov'd out of the Hot-bed, and placed in a warm Situation, where they may remain until the End of *September*, at which Time they muſt be removed into the Green-houſe, placing 'em in a warm Part, but not too cloſe under other Plants. During the *Winter* Seaſon they muſt be now and then gently refreſh'd with Water, but they ſhould not have it given them in large Quantities at that Seaſon; but in the *Summer* they do require to be water'd more plentifully; and at leaſt once a Year they muſt be ſhifted into other Pots of a larger Size, as the Plants advance their Growth, giving 'em freſh Earth, which ſhould be light and rich.

This Plant produces its Flowers near the extreme Parts of the Branches, which altho' not very beautiful, yet for the ſingular Appearance of the hairy Leaves, which adds to the Variety of exotick Plants in the Green-houſe, it deſerves a Place in every curious Garden, eſpecially as it requires no artificial Heat in *Winter*.

The fifth is equally hardy with the common Sort, and riſes to the ſame Height, ſo may be diſpoſed in the ſame manner in Plantations of flowering Shrubs. It may be propagated by laying down the Branches, or by Suckers from the Root, in the ſame Manner as hath been before directed for the common Sort.

SQUASHES, *vide* Melopepo.

SQUILS, *vide* Scilla.

STACHYS, [of Στάχυς, an *Ear of Corn*, becauſe the Flowers of this Plant reſemble an Ear of Corn] Baſe Horehound.

The *Characters* are;

It hath a labiated Flower conſiſting of one Leaf, whoſe Upper-lip is ſomewhat arch'd and erect, and the Under-lip is cut into three Segments, the middle one being larger than the other two; out of the Flower-cup riſes the Pointal, attended by four Embryo's, which afterwards become ſo many Seeds, which are roundiſh, and inclos'd in a Husk, which before was the Flower-cup: To theſe Marks may be added, downy hoary Leaves.

The *Species* are;

1. STACHYS *major Germanica. C. B. P.* Greater German Baſe Horehound.
2. STACHYS *Cretica. C. B. P.* Baſe Hore-hound of Candia.
3. STACHYS *Cretica latifolia. C. B. P.* Broad-leav'd Baſe Horehound of Candia.
4. STACHYS *minor Italica. C. B. P.* Leſſer Italian Baſe Horehound.
5. STACHYS *Canarienſis fruteſcens, verbaſci folio. Tourn.* Canary ſhrubby Baſe Horehound, with a Mullein Leaf.

There are ſeveral other *Species* of this Plant which are preſerv'd in ſome curious Botanick Gardens for Variety; but as they have little Beauty or Uſe, I ſhall not enumerate them here.

The four Sorts firſt mentioned do ſeldom abide longer than two or three Years; for after they have produced Flowers and Seeds, the old Roots are very apt to decay, unleſs part of their Flower-ſtems are taken off early in the *Summer*, which will cauſe them to break out again at Bottom, whereby the Roots may be preſerved.

They are all propagated by Seeds, which ſhould be ſown in *March*, upon a Bed of light, freſh Earth, and when the Plants are come up, they may be planted out into other Beds about ſix Inches aſunder, obſerving to water 'em until they have taken Root, after which they will require no farther Care, but to keep 'em clear from Weeds, 'till *Michaelmas*, when they ſhould be tranſplanted where they are to remain, which muſt be in an open Situation, and upon a dry, light Soil, not too rich, in which they will endure the *Winter* much better than in a rich, ſtrong Soil. The *Summer* following theſe Plants will flower, and in *Auguſt* their Seeds will ripen, when they may be gathered and preſerv'd 'till *Spring* for ſowing.

The fifth Sort is a ſhrubbly Plant, which with us riſes to be ſix or ſeven Feet high; this is propagated by ſowing the Seeds upon a Bed of light, freſh Earth (as the former); and when the Plants are come up, they muſt be tranſplanted into Pots fill'd with freſh, light, ſandy Soil, placing 'em in a ſhady Situation until they have taken Root, after which they may be removed into a more open Expoſure, but in dry Weather muſt be frequently watered: In this Place they may remain until the Middle or Latter-end of *October*, when they muſt be removed into the Green-houſe, placing them in the cooleſt Part, where they may have as much free Air as poſſible, and muſt be often watered, otherwiſe they will ſoon decay.

In *Summer* time theſe Plants will require to be ſhifted twice, adding freſh Earth to their Roots; and if they are only ſhelter'd from hard Froſt in *Winter*, it will be ſufficient, for they are very hardy. The ſecond Year after ſowing, they will produce Flowers and Seeds, and will continue ſo to do every Year after; and although their Flower has no great Beauty, yet, for the Variety of its large, ſoft, woolly Leaves, it deſerves a place amongſt other exotick Plants.

STAMINA or CHIVES, are the ſmall Threads which encompaſs the Style in the Centre of Flowers, upon the Tops of which the Apices or Summits, which contain the Male Duſt, hang.

STAMINEOUS FLOWERS, are ſuch as have a Number of Stamina or Chives, but are deſtitute of the fine colour'd Leaves, which are called Petala, the Stamina being only encompaſſed by the Flower-cup; of this Claſs are *Nettles*, *Spinach*, *Hemp*, *&c.*

STAPHYLODENDRON, [ſo called of ϛαφυλὴ, a *Grape*, and δένδρον, a *Tree*, becauſe its Fruit grows in Cluſters] Bladder-nut.

The *Characters* are;

The Flower conſiſts of ſeveral Leaves, which are placed circularly, and expand in form of a Roſe, out of whoſe many-leav'd Flower-cup riſes the Pointal, which afterwards becomes a membraneous Fruit, ſomewhat like the inflated Bladder of Fiſhes, and divided into two or three Cells, containing Seeds in form of a Skull.

The *Species* are;

1. STAPHYLODENDRON *ſylveſtre & vulgare. H. L.* The common wild Bladder-nut.
2. STAPHYLODENDRON *Virginianum trifoliatum. H. L.* Three-leav'd Virginian Bladder-nut.
3. STAPHYLODENDRON *Africanum, folio ſingulari lucido. Par. Bat.* African Bladder-nut with ſingle ſhining Leaves.
4. STAPHYLODENDRON *Americanum, foliis lauri anguſtis. Plum. Cat.* American Bladder-nut, with narrow Bay-leaves.
5. STAPHYLODENDRON *Americanum, trifoliatum, foliis inciſis. Houſt.* Three leav'd American Bladder-nut, with cut Leaves.

The firſt of theſe Trees is found wild in the Woods and other ſhady Places near *Pontefract* in *Yorkſhire*, and in ſome other Northern Parts of *England*, but near *London* it is preſerved in the Gardens of thoſe who are curious in collecting the various Kinds of hardy Trees.

The ſecond Sort is a Native of *America*, but is ſo hardy as to indure the ſevereſt Cold of our Climate in the open Air, and produces Flowers and Fruit as plentifully in *England* as the common wild Sort.

Both theſe Kinds may be propagated by ſowing their Seeds early in the *Spring*, in Beds of light, freſh Earth, and when the Plants are come up, they muſt be carefully kept clear from Weeds, and in very dry Weather if they are now and then refreſh'd with Water, it will greatly promote their Growth; in theſe Beds they may remain until *March* following, at which Time they ſhould be carefully taken up and planted in a Nurſery, placing 'em in Rows three Feet aſunder, and the Plants eighteen Inches diſtance in the Rows; obſerving to lay a little Mulch upon the Surface of the Ground about their Roots, to prevent the Sun and Wind from penetrating the Ground to dry them; and if the *Spring* ſhould prove very dry, it will be convenient to give 'em a little Water, to encourage their taking Root; after which they will require no farther Care, but to keep the Ground clear from Weeds in *Summer*, and every *Spring* to prune off irregular Branches, and dig the Ground between the Rows, to looſen the Earth, that their Roots may the more eaſily extend. In this Nurſery they may remain two or three Years, by which Time it will be proper to tranſplant them out where they are to remain, either in Wilderneſs Quarters, or in Clumps of various Trees, where they will add to the Diverſity. The beſt Seaſon for tranſplanting theſe Trees is in the *Spring*, juſt before they begin to ſhoot, though they may be tranſplanted in *October* and *November*, as is practis'd for other deciduous Trees.

Theſe do commonly grow in *England* to the Height of twelve or fourteen Feet, ſo ſhould be plac'd with other Trees of the ſame Growth.

They may alſo be propagated by laying down their tender Branches, which will take Root in the Compaſs of one Year, and may afterwards be taken off and tranſplanted, as hath been directed for the *Seedling* Plants.

The *African* Sort does not produce Seeds in this Country, as I could ever obſerve; ſo is only propagated by laying down the tender Branches in the *Spring*, obſerving to notch 'em at a Joint, as is practis'd in laying down Carnations. Theſe, if duly watered in dry Weather, will take Root in the Compaſs of one Year, and may the ſucceeding *Spring* be taken off, and tranſplanted into Pots, fill'd with light, freſh, rich Earth, and placed in a ſhady Part of the Greenhouſe, until they have taken Root, and in *May* they ſhould be carried into the open Air, placing 'em amongſt other exotick Plants, in a warm Situation. During the *Summer* Seaſon they muſt be frequently watered, and when their Roots have fill'd the Pots, they ſhould be removed into larger, obſerving always in ſhifting theſe Plants, to pare off the Earth and Fibres on the Outſide of the Ball, before they are placed into the other Pots, which muſt alſo be filled up with the ſame light rich Earth as before directed. In *Winter* they muſt be houſed with *Oranges*, *Myrtles*, *&c.* being too tender to endure the Cold of our Climate in the open Air, but do require no artificial Warmth in *Winter*; and though the Flowers of this Tree (which it often produces in *England*) are not very beautiful, yet as it retains its Leaves all the *Winter*, which have a very ſhining Appearance, when the Trees are train'd up to regular Heads, it adds greatly to the Beauty of a Green-houſe, when intermix'd with exotick Plants, and deſerves a Place in every good Collection.

The fourth Sort is pretty common in *Jamaica*, *Barbadoes*, and ſome other Places in the warm Parts of *America*, where it uſually riſes to the Height of ten or twelve Feet, and produces its Branches regularly, which are beſet with Leaves, ſhaped in ſome meaſure like thoſe of the Bay-tree, but are narrower and full of Veins, and of a lighter green Colour, the Flowers are ſmall, and of an herbaceous Colour, which are ſucceeded by flat Bladders, having a Border round them, and encloſing two or three roundiſh Seeds.

It may be propagated by Seed, which ſhould be ſown early in the *Spring*, on a moderate Hot-bed, and when the Plants are come up, they ſhould be frequently refreſhed with Water, and kept clear from Weeds, until they have obtained Strength enough to tranſplant, when they ſhould be carefully taken up, and each planted into a ſeparate ſmall Pot filled with freſh light Earth, and then plunged into a Hot-bed of Tanners-bark, where they muſt be carefully ſhaded until they have taken new Root, after which Time they ſhould have free Air admitted to them every Day in warm Weather, by raiſing the Glaſſes of the Hot-bed, and they muſt be conſtantly watered every other Day, during the *Summer* Seaſon. If the Plants thrive they will fill the ſmall Pots with their Roots by the Beginning of *July*, when they muſt be ſhaken out of the Pots, and their Roots trimmed, and then put into Pots a little larger, which ſhould be filled with freſh light Earth, and then plunged again into the Hot-bed, to facilitate their making new Roots; but after this, they ſhould have a larger Share of Air to harden them before *Winter*. At *Michaelmas*, when the Nights begin to be cold, the Plants ſhould be removed into the Stove, where, during the *Winter* Seaſon, they ſhould be kept in a moderate Temperature of Warmth, and muſt be frequently refreſhed with Water, but it ſhould be given to them in ſmall Quantities when the Weather is cold. The following *Summer* the Plants ſhould be by Degrees inured to bear a large Share of Air, but while they are young, they ſhould not be intirely expoſed abroad, tho' when the Plants are become woody, they will bear to be ſet abroad every *Summer*, in a warm ſheltered Situation, and in *Winter* will live in a good Greenhouſe, without any artificial Heat. This Plant doth frequently produce Flowers in this Country, and in warm Seaſons, will ſometimes perfect Seeds. It continues green throughout the Year, ſo will make an agreeable Variety in the Conſervatory in the *Winter* Seaſon, for which it is chiefly preſerved.

The fifth Sort was diſcovered by the late Dr. *William Houſtoun*, at *Campechy*; this Sort hath weak flexible Branches, ſo doth not make a regular Stem like the former, but forms it's ſelf into a rude Buſh. The Flowers of this Kind are produced in Bunches, at the Extremity of the Branches, which are ſucceeded by compreſſed Bladders, very like thoſe of the former Sort.

This Kind may be propagated by Seeds, which muſt be ſown in the ſame Manner as hath been directed for the former Sort, and the Plants muſt be treated much after the ſame Way; but as theſe are ſomewhat tenderer than thoſe, they ſhould not be expoſed abroad in *Summer*, nor will they live tho' the *Winter*, unleſs they are preſerved in a moderate Degree of Warmth.

STAR-WORT, *vide* Aſter.

STAR-FLOWER, *vide* Ornithogalum.

STATICE; Thrift *or* Sea Pink.

The *Characters* are;

It is a Plant with a Flower gathered into an almoſt ſpherical Head, furniſh'd with a common ſcaly Empalement. This Head is compoſed of ſeveral Clove-Gilliflower Flowers, conſiſting of ſeveral Leaves in a proper Empalement, ſhap'd like a Funnel. In like manner the Pointal riſes out of the ſame Empalement, and afterwards turns to an oblong Seed, wrapt up in the Empalement as in a Huſk.

The *Species* are;

1. STATICE. *Lugd.* Thrift, Sea-Gilliflower *or* Sea-Cuſhion.

2. STATICE *montana minor. Tourn.* Leſſer Mountain Thrift *or* Sea-Gilliflower.

3. STATICE *foliis anguſtioribus, flore rubro. Boerh. Ind.* Narrow-leav'd Thrift with red Flowers.

4. STATICE *foliis anguſtioribus, flore albo. Boerh. Ind.* Narrow-leav'd Thrift with a white Flower.

5. STATICE *Luſitanica fruticoſa maritima, magno flore. Tourn.* Shrubby Portugal Sea Thrift with a large Flower.

The firſt of theſe Plants grows wild in *Germany*, and ſome other Inland Countries in great Plenty, from whence it hath been brought into *England*; but the ſecond Sort is found wild in great Plenty in the Salt Marſhes near the Sea, in divers Parts of *England*.

The third and fourth Sorts have been brought into *England* from the *Alps*, or ſome other mountainous Parts, and are preſerv'd for the Beauty of their Flowers in ſome old Gardens.

The fifth Sort is leſs common in *England* than either of the former Sorts, and is only to be found in the Gardens of ſuch as are curious in collecting rare Plants.

The firſt four Sorts have been promiſcuouſly planted in Gardens, to make Edgings on the Sides of Borders in the Flower-gardens, for which Purpoſe they were formerly in great Eſteem, but of late they have been very juſtly rejected for that Uſe, becauſe there was a Neceſſity of tranſplanting theſe Edgings every Year, otherwiſe they could not be kept within due Bounds; beſides, where-ever a Plant fail'd, which was no extraordinary thing, there always appear'd a large unſightly Gap. However, though they are not in uſe at preſent for that Purpoſe, yet a few Plants of the firſt, third, fourth, and fifth Sorts ſhould have a Place in ſome Part of the Flower-Garden, for Variety, eſpecially the third and fourth, which are extreme hardy Plants, and will grow in almoſt any Soil or Situation, and their Flowers will continue a long Time in Beauty.

All theſe Sorts may be propagated by parting their Roots, the beſt Time for which is in *Autumn*, that they may take Root before the Froſt, which will cauſe 'em to flower much ſtronger than thoſe tranſplanted in the *Spring*, and the Plants will not be in ſo much Danger of miſcarrying as thoſe are, eſpecially when the *Spring* happens to prove dry. After theſe Plants have taken Root, they will require no farther Care, but to keep them clear from Weeds, and the *May* following they will begin to flower, which will continue in Beauty three Weeks or a Month, provided the Seaſon be not too hot and dry.

The *Portugal* Sort is not ſo hardy as either of the former, tho' it will endure the Cold of our ordinary *Winters* very well in the open Air, provided it is planted in a dry Soil and a warm Situation, but in very ſevere Froſts it is often deſtroy'd. This may alſo be propagated by Cuttings or Slips, which ſhould be planted in a Bed of freſh Earth in the *Spring*, and water'd and ſhaded until they have taken Root; after which they muſt be kept clear from Weeds till *Michaelmas*, when they ſhould be planted either into Pots to be ſhelter'd in *Winter*, or in ſome warm Situation in the full Ground, where they may remain to flower.

This Plant will grow two or three Feet high, and become ſhrubby, provided it be not injur'd by Cold.

STATUES and VASES contribute very much to the Embelliſhment and Magnificence of a Garden, and extremely advance the natural Beauties of it.

They are made of ſeveral Forms and different Materials; the richeſt are thoſe of Caſt Braſs, Lead gilt, and Marble; the ordinary Sort are of common Stone or *Stucco*.

Among Figures are diſtinguiſh'd Groups, which conſiſt at leaſt of two Figures together in the ſame Block; Figures inſulate or detach'd, that is, thoſe that you can go quite round; and Figures that are ſet in Niches, which are furniſh'd on the fore Part only.

There are likewiſe Buſts, Termes, half-length Figures, Figures half as big as the Life, and thoſe bigger than the Life that are call'd *Coloſſal*, either on regular Pedeſtals, or ſuch as are more ſlender, tapering, and hollow'd, not to mention the Figures which ſometimes adorn Caſcades; as do alſo *Baſs Relievos* and Maſh Heads.

Theſe Figures repreſent all the ſeveral Deities, and illuſtrious Perſons of Antiquity, which ſhould be placed properly in Gardens.

The River Gods, as *Naiades*, *Rivers*, and *Tritons*, ſhould be placed in the Middle of Fountains and Baſons.

The Gods of the Woods, as *Sylvans*, *Fauns*, and *Dryades*, in the Groves; *Sacrifices*, *Bacchanals*, and Childrens Sports are likewiſe repreſented in *Baſs Relievo* upon the *Vaſes* and Pedeſtals, which may be adorn'd with Feſtoons, Foliage, Mouldings, and other Ornaments.

Figures and *Vaſes* are uſually ſet along the Paliſades in the Front, and upon the Sides of a Parterre, in the Niches and Sinking of *Hornbeam* or of Lattice-work made for that Purpoſe.

They are placed in Groves in the Centre of a Star or St. *Andrew*'s Croſs, in the Spaces between the Walls of a Gooſefoot in the Middle of Halls and Cabinets, among the Trees and Arches of a green Gallery, and at the Head of a Row of Trees or Paliſades that ſtand free or detach'd.

In Woods and Groves, *Sylvanus*, God, and *Ferona*, Goddeſs of the Woods; *Acteon* the Hunter, who chancing to eſpy *Diana* bathing, ſhe transform'd him into a Hart, and he was devour'd by his own Dogs: Alſo,

Eccho, a Virgin rejected of her Lover, who pined away in the Woods for Grief, where her Voice ſtill remains, anſwering the Outcries of every Complaint: Alſo,

Philomela transform'd into a *Nightingale*, and *Itis* into a *Pheaſant*.

They are alſo placed at the lower Ends of Walks and Viſta's, to ſet them off the better.

Jupiter, *Mars*, and *Bellona* ſhould poſſeſs the largeſt open Centres and Lawns of a grand Deſign, elevated upon Pedeſtals, columnal and other architectonical Works, with their immediate Servants and Vaſſals underneath, *Jupiter* with his *Mercury*, *Mars* with *Fame*, and the reſt of their Attendants.

Alſo *Minerva* and *Pallas*, Goddeſſes of Wiſdom, with the ſeven liberal Sciences; the three Deſtinies, *Clotho*, *Lacheſis*, and *Atropos*; *Tellus* the God of the Earth; *Priapus* the God of Gardens; *Pytho* the Goddeſs of Eloquence, *Veſta* the Goddeſs of Chaſtity.

Neptune in his Chariot ſhould poſſeſs the Centre of the greateſt Body of Water, whether it be Fountain, Baſon, or whatſoever of that Kind, and attended with the *Naiades*, *Tritons*, and his other Sea Attendants.

For Canals, Baſons, and Fiſh-ponds, *Palæmon*, *Paniſcus*, and *Oceanus*, Gods; *Dione*, *Melicerta*, *Thetis*, and *Marica*, Sea-Goddeſſes; *Salacia*, Goddeſs of the Water; *Naiades*, Fairies of the Water; and the Syrens, *Parthenope*, *Lygia*, and *Leuſia*.

Venus ſhould be placed among the *Graces*, *Aglaia*, *Thalia*, and *Euphroſyne*; *Cupid*, &c.

It may alſo be proper to place *Apollo* with the *Muſes*, *Clio*, *Melpomene*, *Thalia*, *Euterpe*, *Terpſichore*, *Erato*, *Calliope*, *Urania*, and *Polyhymnia*, in the Niches; and *Minerva* with the Liberal Sciences, *&c.* and in all the leſſer Centres of a Polygonal Circumſcription.

Flora and *Cloris*, Goddeſſes of Flowers, and alſo *Venus*, *Daphne* and *Rucina* the Goddeſs of Weeding, in the Flower Garden.

The *Dii Minores* ought alſo to poſſeſs the Niches.

Vulcan with the *Cyclops* in a Centre of leſs Note; and all the reſt of the Deities in their particular Places and Order.

Ceres and *Pomona*, and the three *Heſperides*, *Ægle*, *Arethuſa*, and *Heſperethuſa*, who were three Siſters, feigned to have an Orchard of Golden Apples, kept by a Dragon, which *Hercules* ſlew, when he took them away, ſhould be placed in the Orchard: The *Fauns* and *Sylvans* ſhould be placed in the more remote and rural Centres and Parts of the Wood Work.

Bacchus, the God of Wine, and *Silenus*, in Vineyards.

Daphne and *Diana*, *Flora* and *Venus*, ſhould have their Places in the Flower-garden.

Æolus, God of the Winds, and the *Oreades*, Fairies of the Mountains, ſhould be placed on high Mounts, Terras Walks, *&c.*

The Goddeſs *Vallenta* in Vallies.

Harpocrates and *Angerona*, the former the God, and the latter the Goddeſs of Silence, and *Mercury* the God of Eloquence, in private Cabinets in a Wilderneſs or Grove.

Comus, the God of Banquetting, in Places for that Purpoſe.

Ariſtæus, the Patron of Bees, near an Aviary.

Morpheus and *Pan*, Gods of Sheep, *Pales* the Goddeſs of Shepherds, and *Bubona* the Goddeſs of Oxen, in ſmall Paddocks of Sheep in a Wilderneſs.

Robigus, a God who preſerved Corn from being blaſted, *Ceres* the Goddeſs of Bread Corn, and *Tutelina* a Goddeſs, who had the Tuition of Corn in the Fields, in ſmall Encloſures for Corn in a Wilderneſs.

STELLATE Plants, are ſuch as have their Leaves placed at certain Intervals of the Stalks in form of a Star; of this Tribe are *Madder*, *Gooſe-Graſs*, *Ladies Bedſtraw*, &c.

STERILITY ſignifies Barrenneſs.

STOCK-GILLIFLOWER: *vide* Leucojum.

STOECHAS [ſo called of certain Iſles in the *Mediterranean* Sea, by the *French*, where this Plant was firſt found. In the Shops it is called *Stœchas Arabica*, not becauſe it grows there, but becauſe the *Arabian* Phyſicians do highly commend this Herb] Caſſidony, French Lavender, *or* Stickadore.

The *Characters* are;

It hath a labiated Flower, conſiſting of one Leaf, whoſe upper Lip is upright, and cut in two, but the under Lip (or Beard) is cut into three Parts; but both are ſo divided as at firſt to appear like a Flower cut into five Segments; out of whoſe Flower-cup riſes the Pointal, attended by four Embryo's, which afterwards become ſo many roundiſh Seeds incloſed in the Flower-cup. To theſe Marks muſt be added, that the Flowers are ranged in a various Series into ſcaly Heads, out of the Top of which peep ſome ſmall Leaves, which look very beautifully.

The *Species* are;

1. STOECHAS *purpurea.* *C. B. P.* Purple Stœchas *or* Caſſidony, *commonly called* Arabian Stœchas.
2. STOECHAS *folio ſerrato.* *C. B. P.* Caſſidony *or* French Lavender, with a ſerrated Leaf.
3. STOECHAS *cauliculis non foliatis.* *C. B. P.* Caſſidony, *or* French Lavender, with long naked Flower-ſtalks.

The Heads of Flowers of the firſt Kind are uſed in ſome of the capital Medicines directed by the College of Phyſicians, which are commonly brought from the South Parts of *France*, where the Plants are in great Plenty; but theſe are very apt to take a Mouldineſs in their Paſſage, and ſo are not near ſo good for uſe as thoſe which are gathered freſh in *England*, where the Plants may be cultivated to great Advantage.

The ſecond and third Sorts are preſerved in many curious Gardens for Variety, but they are not of any uſe.

All theſe Plants may be cultivated by ſowing their Seeds upon a Bed of light dry Soil in *March*; and when the Plants are come up, they ſhould be carefully cleared from Weeds until they are two Inches high, at which Time they ſhould be removed; therefore there muſt be a Spot of light dry Ground prepared, and laid level, which muſt be trodden out in Beds, into which the Plants ſhould be planted at about five or ſix Inches Diſtance each Way, obſerving to water and ſhade them until they have taken Root, after which they will require no further Care, but to keep them clear from Weeds the following *Summer*; but if the *Winter* ſhould prove very ſevere, it will be proper to cover them with Mats, *Peaſe-haulm*, or ſome other light covering to guard them againſt the Froſt, which otherwiſe would be apt to injure them while they are ſo young! But in *March*, or the Beginning of *April*, the following *Spring*, they muſt be removed into the Places where they are to remain, obſerving, if poſſible, to tranſplant them in a warm moiſt Seaſon, and not to let them remain long above Ground, for if their Roots are dry'd, they ſeldom grow well after. The Soil in which theſe are planted ſhould be a dry warm Sand or Gravel, and the poorer the Soil is in which they are planted, the better they will endure the Cold of the *Winter*, provided the Ground be dry; tho' indeed the Plants will thrive better in *Summer* upon a rich moiſt Ground; but then they will not produce ſo many Flowers, nor will the Plant afford near ſo ſtrong an aromatick Scent; as is the Caſe with moſt Sorts of aromatick Plants.

Theſe Plants may alſo be propagated by planting Slips or Cuttings of any of the Kinds in the *Spring*, obſerving to refreſh them with Water until they have taken Root, after which they may be managed as hath been directed for the ſeedling Plants; but as thoſe Plants raiſed from Seeds are much better than theſe, it is hardly worth while to propagate them this Way, eſpecially ſince their Seeds do ripen ſo well in this Country.

The Heads of the firſt Sorts may be gathered for uſe when the Flowers are in full Perfection, and ſpread to dry in a ſhady Place, after which they may be put up for Uſe.

STONECROP, *vide* Sedum.

STONECROP-TREE, *vide* Vermicularis Frutex.

STOVES are Contrivances for the preſerving ſuch tender exotick Plants, which will not live in theſe Northern Countries without artificial Warmth in *Winter*. Theſe are built in different Methods, according to the Ingenuity of the Artiſt, or the different Purpoſes for which they are intended; but in *England* they are at preſent reducible to two.

The firſt is called a *Dry Stove*, being ſo contrived, that the Flues thro' which the Smoak paſſes are either carry'd under the Pavement of the Floor, or elſe are erected in the Back-part of the Houſe, over each other, like Steps: In theſe *Stoves* the Plants are placed on Shelves of Boards, laid on a Scaffold above each other, for the greater Advantage of their ſtanding in ſight, and enjoying an equal Share of Light and Air. In theſe *Stoves* are commonly placed the tender Sorts of *Aloes*, *Cereus's*, *Euphorbiums*, *Tithymals*, and other ſucculent Plants, which are impatient of Moiſture in *Winter*, and therefore require to be kept in a ſeparate *Stove*, and not placed among Trees or herbaceous Plants, which perſpire freely, and thereby often cauſe a damp Air in the Houſe, which is often imbibed by the ſucculent Plants, to their no ſmall Prejudice. Theſe *Stoves* may be regulated by a *Thermometer*, ſo as not to over-heat them, nor to let the Plants ſuffer by Cold; in order to which, all ſuch Plants as require nearly the ſame Degree of Heat ſhould be placed by themſelves in a ſeparate Houſe; for if in the ſame *Stove* there are Plants placed of many different Countries, which require as many different Heats, by making the Houſe warm enough for ſome Plants, others, by having too much Heat, are drawn and ſpoiled.

The other Sort of *Stoves* are commonly called *Bark Stoves*, to diſtinguiſh them from the *Dry Stoves* already mentioned. Theſe have a large Pit, nearly the Length of the Houſe, three Feet deep, and ſix or ſeven Feet wide, according to the Breadth of the Houſe; which Pit is filled with freſh *Tanners-bark* to make a Hot-bed, and in this Bed the Pots of the moſt tender exotick Trees and herbaceous Plants are plunged; the Heat of this Bed being moderate, the Roots of the Plants are always kept in Action, and the Moiſture detained by the Bark keeps the Fibres of their Roots in a ductile State, which in the *Dry Stove*, where they are placed on Shelves, are ſubject to dry too faſt, to the great Injury of the Plants. In theſe *Stoves* (if they are rightly contrived) may be preſerved the moſt tender exotick Trees and Plants, which, before the Uſe of the Bark was introduced, were thought impoſſible to be kept in *England*: But as there is ſome Skill required in the Structure of both theſe *Stoves*, I ſhall not only deſcribe them as intelligibly as poſſible, but alſo annex a Plan of the *Bark Stove* hereto, by which it is hoped every curious Perſon will be capable of directing his Workmen in their Structure.

The Dimenſion of this *Stove* ſhould be proportioned to the Number of Plants intended to be preſerved, or the particular Fancy of the Owner; but their Length ſhould not exceed forty Feet, unleſs there are two Fire-places, and in that Caſe it will be proper to make a Partition of Glaſs in the Middle, and to have two Tan-pits, that there may be two different Heats, for Plants from different Countries (for the Reaſons before given in the Account of *Dry Stoves*); and were I to erect a Range of *Stoves*, they ſhould be all built in one, and only divided with Glaſs Partitions, which will be of great Advantage to the Plants becauſe they may have the Air in each Diviſion ſhifted by ſliding the Glaſſes of the Partitions, or by opening the Glaſs Door, which ſhould be made between each Diviſion, for the more eaſy Paſſage from one to the other.

This *Stove* ſhould be raiſed above the Level of the Ground, in Proportion to the Dryneſs of the Place; for if it be built on a moiſt Situation, the Whole ſhould be placed upon the Top of the Ground; ſo that the Brickwork in Front muſt be raiſed three Feet above the Surface, which is the Depth of the Bark-bed, whereby none of the Bark will be in Danger of lying in Water; but if the Soil be dry, the Brick-work in Front need not be more than one Foot above Ground, and the Pit may be ſunk two Feet below the Surface. Upon the Top of this Brick-work, in Front, muſt be laid the Plate of Timber, into which the Wood-work of the Frame is to be faſtened, and the upright Timbers in Front muſt be placed four Feet aſunder, or ſomewhat more, which is the Proportion of the Width of the Glaſs Doors or Saſhes; theſe ſhould be about ſix Feet and a half or ſeven Feet long, and placed upright; but from the Top of theſe ſhould be ſloping Glaſſes, which ſhould reach within three Feet of the Back of the *Stove*, where there ſhould be a ſtrong Crown-piece of Timber placed, in which there ſhould be a Groove made for the Glaſſes to ſlide into. The Wall in the Back-part of the *Stove* ſhould be thirteen Inches thick, and carry'd up about nine Feet above the Surface of the Bark-bed; and from the Top of this Wall there ſhould be a ſloping Roof to the Crown-piece where the Glaſſes ſlide in. This Crown-piece ſhould be about ſixteen Feet high from the Surface of the Bark-bed or Floor, which will give a ſufficient Declivity to the ſloping Glaſſes to carry off the Wet, and be of a reaſonable Height for containing many tall Plants. The Back Roof may be ſlated, covered with Lead, or tiled, according to the Fancy of the Owner: But the Manner of this outſide Building is better expreſſed by the annexed Plan, than is poſſible to be deſcribed in Words.

In the Front of the Houſe there ſhould be a Walk about twenty Inches wide, for the Conveniency of walking, next to which the Bark-pit muſt be placed, which ſhould be in Width proportionable to the Breadth of the Houſe: If the Houſe is twelve Feet wide, which is a due Proportion, the Pit may be ſeven Feet wide; and behind the Pit ſhould be a Walk eighteen Inches wide, to paſs in order to water the Plants, &c. then there will be twenty-two Inches left next the Back-wall to erect the Flues, which muſt be all raiſed above the Top of the Bark-bed; theſe Flues ought to be ſixteen Inches wide in the Clear, that they may not be too ſoon ſtopped with the Soot; and the lower Flue, into which the Smoak firſt enters from the Fire, ſhould be two Feet deep in the Clear, and this may be covered either with Caſt Iron Plates or broad Tiles; over this the ſecond Flue muſt be returned back again, which may be eighteen Inches deep, and covered on the Top as before; and ſo in like Manner the Flues may be returned over each other three or four times, that the Heat may be ſpent before the Smoak paſſes off. The Thickneſs of the Wall in Front of theſe Flues need not be more than four Inches, but muſt be well jointed with Mortar, and plaiſtered within-ſide, to prevent the Smoak from getting into the Houſe, and the Outſide ſhould be faced with Mortar, and covered with a coarſe Cloth, to keep the Mortar from cracking, as is practiſed in ſetting up Coppers; if this be carefully done, there will be no Danger of the Smoak entering the Houſe, which cannot be too carefully avoided; for there is nothing more injurious to Plants than Smoak, which will cauſe them to drop their Leaves, and if it continue long in the Houſe, will entirely deſtroy them.

A The ground plat of the Stove B The Bark bed in the Stove C The Shed for the Fire place

Fire-place may be made either at one End or in the according as there is moſt Conveniency, for where- is placed, it ſhould have a Shed over it, and not be to the open Air; for it will be impoſſible to make e burn equally, where the Wind has full Egreſs to it, ill be troubleſome to attend the Fire in wet Weather, it is expoſed to the Rain.

Contrivance of the Furnace muſt be according to the hich is deſigned to burn; but as Turf is the beſt Fir- *Stoves*, where it can be had, becauſe it burns more ately, and laſts longer than any other Sort of Fuel, and uires leſſer Attendance, I ſhall deſcribe a proper Sort of ce for that Purpoſe.

e whole of this Furnace ſhould be erected within the , which will be a great Addition to the Heat, and the Wall on the Outſide of the Fire-place, next the Shed, d be two Bricks thick, the better to prevent the Heat coming out that Way. The Door of the Furnace, hich the Fuel is put in, muſt be as ſmall as convenient- ay be to admit of the Fuel; and this Door ſhould be ed near the upper Part of the Furnace, and made to ſhut loſe as poſſible, ſo that there may but little of the Heat ff through it. This Furnace ſhould be about twenty hes deep; and ſixteen Inches ſquare at Bottom, but may loped off on every Side, ſo as to be two Feet ſquare at Top; and under this Furnace ſhould be a Place for the s to fall into, which ſhould be about a Foot deep, and ide as the Bottom of the Furnace; this ſhould alſo have Iron Door to ſhut as cloſe as poſſible; but juſt over the -hole, above the Bars which ſupport the Fuel, ſhould be uare Hole about four Inches wide, to let in Air to make Fire burn; this muſt alſo have an Iron Frame, and a r to ſhut cloſe when the Fire is perfectly lighted, which make the Fuel laſt the longer, and the Heat will be e moderate.

The Top of this Furnace ſhould be nearly equal to the p of the Bark-bed, that the loweſt Flue may be above Fire, ſo that there may be a greater Draught for the k, and the Furnace ſhould be covered with a large Iron e, cloſely cemented to the Brick-work, to prevent the k from getting out: And you ſhould be very careful, ever the Fire is placed, that it be not too near the Bark- d; for the Heat of the Fire will, by its long Continu- e, dry the Bark, ſo that it will loſe its Virtue, and be Danger of taking Fire; to prevent which, it will be the Method to continue a Hollow between the Brick-work the Fire and that of the Pit, about eighteen Inches wide, ich will effectually prevent any Damage ariſing from the at of the Fire; and there ſhould be no Wood-work pla- d any where near the Flues or the Fire-place, becauſe the ntinual Heat of the *Stove* may in Time dry it ſo much as cauſe it to take Fire, which ought to be very carefully arded againſt.

The Entrance into this *Stove* ſhould be either from a Green-houſe, the *Dry Stove*, or elſe thro' the Shed where e Fire is made, becauſe in cold Weather the Front Glaſſes uſt not be open'd. The Inſide of the Houſe ſhould be ean white-waſhed, becauſe the whiter the Back-part of the Houſe is, the better it will reflect the Light, which is of eat Conſequence to Plants, eſpecially in *Winter*, when the *ove* is obliged to be ſhut up cloſe.

Over the Top Sliding Glaſſes there ſhould be either Wooden hutters, or Tarpawlins to roll down over them in bad Wea- her, to prevent the Wet from getting through the Glaſſes, d to ſecure them from being broke by Storms of Hail, and eſe outer Coverings will be very ſerviceable to keep out the roſt; and if in very ſevere Cold there is a Tarpawlin hung efore the upright Glaſſes in the Front, it will be of great rvice to the *Stove*, and a much leſs Fire will preſerve a Heat the Houſe.

In the warmeſt of theſe Houſes or Diviſions ſhould be pla- d the moſt tender exotick Trees and Plants, a Liſt of hich is as followeth.

ajou or *Caſhew*,
egator Pear,
ſpice or *Pimento*,
rrow Root,
ananas,
aſtard Cedar of *Barbados*,
aſtard Locuſt of *Barbados*,
ully Tree,
utton Wood of *Barbados*,
abbage Tree,
ocoa Tree,
alibaſh Tree,
aſſada,
Caſſia Fiſtula,
Cedar Tree of *Barbados*,
Cherry Tree of *Barbados*,
Cocoa-nut Tree,
Cortex Winteranus,
Cuſtard Apple,
Date Tree,
Dumb Cane,
Fiddle Wood,
Fig Tree the *Arched Indian*,
Flower-fence of *Barbados*,
Fuſtick Tree,
Ginger.
Guajacum,
Guayava Tree,
Logwood,
Macaw Tree,
Mamee Tree,
Mancinel Tree,
Mimoſa or *Senſitive Plants*,
Nickar Tree or *Bonduc*,
Palm Trees of ſeveral Sorts,
Papaw Tree,
Plantane Tree,
Plum Tree of *Jamaica*,
Sapotilla Tree,
Sope Berry Tree,
Sowre-ſop,
Sugar Apple,
Sweet-ſop,
Tamarind Tree,
Tulip Flower or *Whitewood*.

Theſe with moſt other Sorts of Trees, Shrubs, and herbaceous Plants, ſhould be plunged in the Bark-bed for the Reaſons already aſſigned; and upon the Top of the Flues may be ſet the *Anana* or *Pine-Apple* Plants in *Winter*, as alſo the *Melon-thiſtle*, the tender Sorts of *Cereus's*, and *Euphorbiums*, with other very tender ſucculent Plants, which require to be kept dry in *Winter*.

As in this *Stove* are placed the Plants of the hotteſt Parts of the *Eaſt* and *Weſt Indies*, ſo the Heat ſhould be kept up equal to that marked *Anana* upon Mr. *Fowler's Thermometers*, and ſhould never be ſuffered to be above eight or ten Degrees cooler at moſt, nor ſhould the Spirit be raiſed above ten Degrees higher in the Thermometer; both which Extremes will be equally injurious to the Plants.

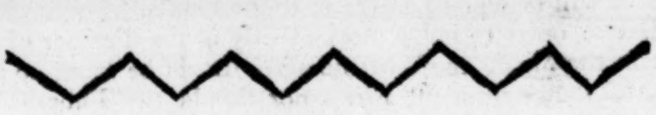
But in order to judge more exactly of the Temper of the Air in the *Stove*, the Thermometer ſhould be hung up at a good Diſtance from the Fire, nor ſhould the Tube be expoſed to the Sun, but on the contrary, the Back hung thereto, becauſe whenever the Sun ſhines upon the Ball of the Thermometer but one ſingle Hour, it will raiſe the Liquor in the Tube conſiderably, when perhaps the Air of the Houſe is not near ſo warm; which many times deceives thoſe who are not aware of this.

In the Management of the Plants placed in the Bark-bed, there muſt be a particular Regard had to the Temper of the Bark, and the Air of the Houſe, that neither be too violent; as alſo to water them frequently, becauſe when they are in a continual Warmth, which will cauſe them to perſpire freely, if they have not a conſtant Supply to anſwer their Diſcharge, their Leaves will decay, and ſoon fall off. As to the farther Directions concerning the Culture of the particular Plants, the Reader is deſired to turn to their ſeveral Articles, where they are diſtinctly treated of.

The other Sort of *Stove*, which is commonly call'd the *Dry Stove* (as was before ſaid) may be either built with upright and ſloping Glaſſes at the Top, in the ſame Manner, and after the ſame Model of the *Bark-ſtove*; or elſe the front Glaſſes, which ſhould run from the Floor to the Ceiling, may be laid ſloping, to an Angle of 45 Degrees, the better to admit the Rays of the Sun in *Spring* and *Autumn*: The latter Method has been chiefly follow'd by moſt Perſons who have built theſe Sort of *Stoves*; but were I to have the Contrivance of a *Stove* of this kind, I would have it built after the Model of the *Bark-ſtove*, with upright Glaſſes in Front, and ſloping Glaſſes over them, becauſe this will more eaſily admit the Sun at all the different Seaſons; for in *Summer*, when the Sun is high, the Top Glaſſes will admit the Rays to ſhine almoſt all over the Houſe; and in *Winter*, when the Sun is low, the Front Glaſſes will admit its Rays; whereas when the Glaſſes are laid to any Declivity in one Direction, the Rays of the Sun will not fall directly thereon above a Fortnight in *Autumn*, and about the ſame Time in *Spring*, and during the other Parts of the Year they will fall obliquely thereon, and in *Summer*, when the Sun is high, the Rays will not reach above five or ſix Feet from the Glaſſes; for the Proof of this ſee the Article *Sun*. Beſides, the Plants plac'd toward the Back-part of the Houſe will not thrive in the *Summer* Seaſon for want of Air, whereas when there are ſloping Glaſſes at the Top, which run within four Feet of the Back of the Houſe, theſe, by being drawn down in hot Weather, will let in perpendicular Air to all the Plants; and of how much Service this is to all Sorts of Plants, every one who has had Opportunity of obſerving the Growth of Plants in a *Stove*, will eaſily judge: For when Plants are plac'd under Cover of a Ceiling, they always turn themſelves toward the Air and Light, and thereby grow crooked; and if in order to preſerve them ſtrait, they are turn'd every Week, they will nevertheleſs grow weak, and look pale and ſickly, like a Perſon ſhut up in a Dungeon; for which Reaſons, I am ſure, whoever has made Trial of both Sorts of *Stoves*, will readily join with me to recommend the Model of the *Bark-ſtove* for every Purpoſe.

As to the farther Contrivance of this *Stove*, it will be neceſſary to obſerve the Temper of the Place, whether the Situation be dry or wet; if it be dry, then the Floor need not be rais'd above two Feet above the Level of the Ground;

but if it be wet, it will be proper to raiſe it three Feet, becauſe as theſe Flues are to be carry'd under the Floor, ſo when they are made under, or cloſe upon the Surface of the Ground, they will raiſe a Damp, nor will the Flues draw ſo well as when they are more elevated. The Furnace of this *Stove* may be either plac'd at one End of the Houſe, or at the Back-part thereof, according to the Conveniency of the Building. This muſt be made according to the Fuel intended to burn, which, if for Coals or Wood, may be made according to the common Method for Coppers, but only much larger, becauſe as the Fire is to be continu'd in the Night chiefly, ſo if there is not Room to contain a great Quantity of Fuel, it will occaſion a great deal of Trouble in tending upon the Fire in the Night, which ſhould be avoided as much as poſſible, becauſe whenever the Trouble is made very great or difficult, and the Perſon who is intruſted with the Care of it has not a very great Affection for the Thing, and is withal not very careful, there will be great Hazard of the Fire being neglected, which in a little time would be of dangerous Conſequence to the Plants: But if the Fuel intended be Turf, then the Contrivance of the Furnace may be the ſame as for the *Bark-ſtove* already mention'd. The Flues of this *Stove* ſhould be turn'd in Angles after the following Manner.



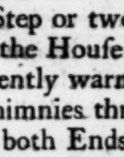
which will cauſe them to draw better than if ſtrait, and by this Method of diſpoſing them, they will reach from the Back to the Front of the Houſe.

The Depth of them ſhould not be leſs than eighteen Inches, and the Width nearly equal, which will prevent their being choak'd up with Soot, as is often the Caſe when the Flues are made too ſmall. The Spaces between the Flues ſhould be fill'd up either with dry Brick Rubbiſh, Lime, or Sand, from which there will little Moiſture ariſe; and the Flues ſhould be cloſely plaiſter'd with Loam both within and without, and the upper Part of them cover'd with a coarſe Cloth under the Floor, to prevent the Smoak from getting into the Houſe.

When the Flue is carry'd from the Furnace on the End of the Houſe, it may be return'd in the Back above the Floor in a ſtrait Line, which may be contriv'd to appear like a Step or two, by which Means the Smoak will be continu'd in the Houſe until all its Heat is ſpent, which will conſequently warm the Air of the Houſe the better; and the Chimnies thro' which the Smoak is to paſs off, may be either at both Ends or in the Middle, carry'd up in the Thickneſs of the Brick-work of the Walls, ſo as not to appear in Sight; the Flues ſhould be firſt cover'd either with Iron Plates or broad Tiles, and then a Bed of Sand over them about two Inches thick, upon which the plain Tiles ſhould be laid to correſpond with the reſt of the Floor. This thickneſs of Cover will be full enough to prevent the too ſudden Riſe of the Heat from the Flues.

But if the Furnace is placed under the Floor, the Thickneſs of Sand between the Iron Plate which cover it and the Floor, ſhould not be leſs than four Inches, ſo that the Bottom of the Furnace ſhould be ſunk the lower; and if from the Fire-place to the End of the Houſe, the Flues are laid a little riſing, it will cauſe them to draw the better; but this Riſe muſt be allowed in the placing them lower under the Floor next the Fire, becauſe the Floor muſt be laid perfectly level, otherwiſe it will appear unſightly.

In this *Stove* there ſhould be a Stand or Scaffold erected for placing Shelves above each other in the Manner annexed, that the Plants may be diſpoſed above each other, ſo as to make a handſome Appearance in the Houſe; but theſe Shelves ſhould be made movable, ſo as to be raiſed or ſunk, according to the various Heights of the Plants, otherwiſe it will be very troubleſome to raiſe or ſink every particular Plant according to their Heights, or every Year as they advance.



In placing the Feet of this Stand, you muſt be careful not to ſet them too near the Fire, nor directly upon the Top of the Flue, (eſpecially at that End next the Fire) leſt by the conſtant Heat of the Tiles the Wood ſhould take Fire, which can't be too much guarded againſt, ſince ſuch an Accident would go near to deſtroy all the Plants, if the Houſe eſcap'd being burnt. This Stand or Scaffold ſhould be plac'd in the Middle of the Houſe, leaving a Paſſage about two Feet and a half in the Front, and another of the ſame Width in the Back, for the more conveniently paſſing round the Plants to water them, and that the Air may freely circulate about them. In diſpoſing the Plants, the talleſt ſhould be plac'd backward, and the ſmalleſt in Front, ſo that there will not be Occaſion for more than five or ſix Shelves in Height at moſt; but the Scaffold ſhould be ſo contriv'd, that there may be two or three Shelves in Breadth laid upon every Riſe whenever there may be Occaſion for it, which will ſave a deal of Trouble in diſpoſing of the Plants.

In the Erection of theſe *Stoves*, it will be of great Service to join them all together, with only Glaſs Partitions between them, (as was before obſerv'd); and where ſeveral of theſe *Stoves* and *Greenhouſes* are requir'd in one Garden, then it will be very proper to have the *Greenhouſe* in the Middle, and the *Stoves* at each End, either in the Manner directed in the Plan of the *Greenhouſe* exhibited in that Article, or carry'd on in one ſtrait Front: And in the Contrivance of theſe it may be ſo order'd, that upon opening an Iron Regulator plac'd at the End of the angular Flue of the *Stove*, and ſtopping another plac'd at the Entrance of the back Flue, the Smoak may be made to paſs thro' the *Greenhouſe* in extreme hard Froſt, which will be ſufficient to prevent its ever freezing in the Houſe: For want of which Contrivance, it is hardly poſſible to keep out the Froſt in very ſevere *Winters*.

By this Contrivance in the Structure of theſe Houſes, a Perſon may paſs from one to the other of them without going into the open Air; which, beſides the Pleaſure to the Owner, is alſo of great Uſe, becauſe there will be no Occaſion of making a Back-way into each of them, which otherwiſe muſt be, becauſe the Front Glaſſes of the *Stoves* ſhould not be open'd in cold Weather, if it can poſſibly be avoided on any Account, becauſe the cold Air ruſhing in, will greatly prejudice the very tender Plants.

But beſides the *Stoves* here deſcrib'd, and the *Greenhouſe*, it will be very neceſſary to have a Glaſs-Caſe or two, whereever there are great Collections of Plants. Theſe may be built exactly in the manner already deſcrib'd for the *Stoves*, with upright Glaſſes in Front, and ſloping Glaſſes over the Top of them, which ſhould run within four Feet of the Back of the Houſe. The Height, Depth, and other Dimenſions ſhould be conformable to that of the *Stoves*, which will make a Regularity in the Building. Theſe may be plac'd at the End of the Range on each Hand beyond the *Stoves*; and if there be a Flue carry'd along under the Floor of each, which may be open'd in ſevere Froſt, (in the manner already directed for that under the Greenhouſe) and the Smoak of the adjoining *Stove* made to paſs off through theſe, it will ſave a great deal of Labour, and prevent the Froſt from ever entering the Houſe, be the *Winter* ever ſo ſevere: But the Upper Glaſſes of theſe Houſes ſhould have either Shutters to cover them, or elſe Tarpawlins to let down over them in froſty Weather; and if there is a Contrivance to cover the upright Glaſſes in Froſt, either with Mats, Shutters, or Tarpawlins, it will be of great Uſe in *Winter*, otherwiſe the Flue muſt be open'd when the Froſt comes on, which ſhould not be done but upon extraordinary Occaſions; becauſe the Deſign of theſe Houſes is, to keep ſuch Plants as require only to be preſerv'd from Froſt, and need no additional Warmth, but at the ſame time, require more Air than can conveniently be given them in a Greenhouſe: In one of theſe Houſes may be plac'd all the Sorts of *Ficoides*, *African Sedums*, *Cotyledons*, *Senecio's*, and other Succulent Plants from the *Cape of Good Hope*. In the other may be plac'd the ſeveral Kinds of *Anemonoſpermos's*, *Jacobæa's*, *Doria's*, *Alaternoides's*, and other woody or herbaceous Plants from the ſame Country, or any other in the ſame Latitude.

Thus by contriving the Greenhouſe in the Middle, and two *Stoves* and a Glaſs-Caſe at each End, there will be Conveniency to keep Plants from all the different Parts of the World, which can be no otherwiſe maintain'd but by placing them in different Degrees of Heat, according to the Places of their native Growth.

Since the above Account of the Stoves was firſt publiſhed, there hath been a great Number of them built in *England*; and theſe have been projected in different Manners, according to the ſeveral Plants which they were deſign'd to contain. So that there has been very great Improvements made in theſe Contrivances, but eſpecially in the Stoves for the *Ananas* or Pine-apple, which Fruit, is now pretty commonly cultivated in the *Engliſh* Gardens, and the Method of cultivating them more generally known, ſo that the Expence of maintaining them is greatly diminiſhed. But notwithſtanding what has been by ſome affirmed, *viz.* that they may be propagated in Hot-beds without any Stoves, yet, from a Number of Trials, I am convinced, that is a more expenſive Method, and attended with a much greater Uncertainty, than when they are kept in Stoves; for in thoſe Hot-beds, when foggy cloudy Weather happens, which is too frequent in the *Winter* Seaſon in this Country, there muſt be an extraordinary Care taken to prevent the Damp (which will at ſuch Times be very great in the Beds) from rotting the Plants; and in very cold Weather, theſe Beds muſt be lined round the Sides with hot Dung, to keep a Warmth in the Bed, and this muſt be repeated three or four Times in a *Winter*, according to the Cold of the Seaſon, without which the Plants will not thrive. So that the Trouble of doing this is very great, and where Dung is ſcarce, is alſo expenſive, and in this Method there is no Certainty of having any Quantity of Fruit: for I have obſerved where the Plants have been thus managed, few of them have produced Fruit, and ſome Years they have intirely miſcarried, whereas thoſe in Stoves do ſeldom fail, when the Plants are of a proper Size for bearing. And after the firſt Expence of building the Stove, the Charge is not very great to maintain the Plants, for a ſmall Quantity of Fuel will be ſufficient to warm a Stove, which is capable of containing fourſcore or a hundred Plants, and a leſs Quantity of Tan will be required for them, than when they are kept in Frames. In a Stove of twenty-four Feet long, and about eight Feet abroad (excluſive of the Flues) may be placed about one hundred Plants to bear Fruit, (provided they are planted in the Tan, which is found to be the beſt Method, and of which I ſhall give a particular Account hereafter). The Stove may be kept warm during the *Winter* Seaſon, with two Chauthern and a half, or at moſt three Chauthern of Coals, or with any other Sort of Fuel in proportion; but where Coal can be had at an eaſy Expence, it is much the beſt Fuel, becauſe the Smoak of this will keep warm much longer than of any other Fuel, ſo will heat the Flues much more, and it will make much leſs Soot, than Turf or any ſuch Fuel, which is an Advantage, becauſe the Flues will not require to be ſo often cleaned.

I ſhall now proceed to give a Deſcription of two Sorts of Stoves, which have of late been invented for the *Ananas*, in both which they are found to ſucceed equally. The firſt of theſe Stoves, has but one Slope of Glaſſes, from the Top to the Plate, which is raiſed about a Foot above the Level of the Ground (provided the Soil is dry, otherwiſe it muſt be advanced higher, ſo as that the Bark-pit may not deſcend ſo low as to be ever troubled with Water, which would cool the Tan and ſpoil the Bed). The other Sort of Stove, has upright Glaſſes in Front, about four Feet high, and from the upper Part of theſe are ſloping Glaſſes, which run up to the Top. The Deſign of theſe upright Glaſſes in Front, is to admit of a ſmall Walk between the Bark-pit and the Glaſſes, for the more convenient paſſing round the Plants to water them, *&c.* which in other Stoves cannot be done, ſo that the Glaſſes muſt be opened to come at the front Row of Plants, whenever they want to have any Thing done to them: tho' as to the watering of the Plants, that may be very well performed, from the Walk on the back of the Tan-bed, with a long ſpouted watering Pot, ſo that there will be no Neceſſity of opening the Glaſſes, but on particular Occaſions. Theſe ſmall Stoves, with one ſlope of Glaſſes, are contrived to ſave Expence, and where Perſons are confined for Room. And as they contain a much leſs Quantity of Air than the other Stoves, ſo a ſmaller Quantity of Fuel will keep them warm; but the other being the more commodious, is by many People preferred to theſe. However, I ſhall give as plain Directions as poſſible, for the building both theſe Kinds of Stoves, which with the annexed Plates, will be ſufficient Inſtructions for any Perſon, who is the leaſt ſkilled in Buildings, to make either of the Stoves.

The firſt Plate contains a Plan of the ſmall Stove, with one Slope of Glaſſes, with a Section of the Flues, a Plan of the Tan-bed, and of the Furnace, with the ſloping Glaſſes. The Length from out-to-out of this Stove, is twenty four Feet; and in the Width eleven Feet. The Walls in Front, and at each End are one Brick and a half in Thickneſs, and the back Wall muſt be two Bricks thick, in order to throw the Heat into the Houſe, becauſe to this Wall the Flues are built. The Pit, which contains the Tan, is the whole Length of the Building, and ſix Feet wide, but the Depth need not be more than two Feet and a half, which will hold a ſufficient Quantity of Tan, to contain a moderate Warmth ſo long as is neceſſary. This Pit ſhould be brick'd at bottom, to prevent the Earth mixing with the Tan; the Wall in Front of the Stove, as alſo thoſe at each End, to encompaſs this Pit three Ways, ſo there muſt be a nine Inch Wall carried up on the Back-ſide, to which the Wall which ſuſtains the Flues, will almoſt join; for in carrying up the back Wall of the Stove, it will be proper to make the Foundation ſo broad, as to include the Width of the Flues (which muſt be two Feet nine Inches) that the Work may ſettle equally. From this Foundation, to the Side of the Bark-pit, there will be two Feet, including the nine Inch Wall of the Pit, ſo that the other fifteen Inches, may be filled up with Rubbiſh, to ſave the Expence of Bricks, ſince it is only to ſupport the Pavement of the Walk. In carrying up the back Wall of the Stove, the Flues ſhould alſo be carried up with it, that the Covering of each Flue may be joined into the ſolid Brick-work of the Wall. The lower Part of the bottom Flue, ſhould be level with the Pavement of the Walk, that the Heat may be intirely above Ground. The Depth of the firſt Flue ſhould be two Feet, becauſe in this the greateſt Quantity of Soot will lodge, and the Width muſt be as much as a Foot-tile may reach to cover; which may be about ten Inches; for if the Tiles have an Inch on each ſide bearing, it will be ſufficient, ſince they are not to ſupport any Weight; but where the Flues are covered with flat Stones, which will admit of their being made wider, it will be proper to allow them fifteen Inches wide, which give better Room to cleanſe them. This Wall in Front of the Flues, withinſide of the Houſe, ſhould not be above four Inches thick, that the Smoak, in paſſing thro' the Flues, may ſend the Heat more eaſily into the Stove. The other three Flues ſhould be eighteen Inches deep, and all of them the ſame Width of the lower one; which will be large enough for a Chimney Sweeper to go thro' them, to cleanſe them of the Soot, whenever they are foul. Theſe Flues turning four times (as in the annexed Plan) will riſe almoſt to the Top of the Stove; for as the Uſe of theſe Stoves is to contain *Ananas*, which are low Plants, ſo if there is but Height enough for a Man to walk upright on the Walk at the Backſide of the Houſe, between the Pit and the Flues, it will be ſufficient; for the lower the Stoves are built, the leſs Quantity of Fuel will keep it warm in Winter; but as it will be neceſſary to build the Back-wall ſix Feet and a half high to contain the Flues, ſo by raiſing it one Foot higher, there will be upward of ſix Feet in Height, notwithſtanding the Slope of the Front. The Flues ſhould be well plaiſtered with Loam and Dung within-ſide, which ſhould be laid as ſmooth as poſſible, that the Smoak may not be the leaſt obſtructed in its paſſing thro' them; and when they are carried quite up, the Whole ſhould be plaiſtered on the Side within the Stove, with Lime and Hair, and covered cloſely with Hop-bags, or other coarſe Cloth, after the Manner as Coppers are uſually done, which will prevent the Smoak from getting thro' into the Stove, and faſten the whole Work together.

In the Front-ſlope, the Glaſſes need not be carried to the Top of the Building, but the upper Part may be boarded, and covered, either with Slates or Lead, about three Feet and a half below the Top, which will cover the Flues and the Walk; ſo that the Glaſſes, which muſt run up juſt under this Covering, will extend over the Bark-bed, and the Plants will enjoy the full Advantage of the Sun and Light.

On the Backſide of the Stove, at one End, muſt be built a ſmall Shed, in which the Furnace muſt be placed, which ſhould be ſunk ſo low, as that the Top of the Oven may be ten Inches, or a Foot below the firſt Flue, which will occaſion a good Draught to the Smoak. This Oven need not be very large for theſe ſmall Stoves, about ſixteen Inches wide, and twenty Inches long within-ſide will be ſufficient. To this Oven there muſt be an Iron Door, ſomewhat like thoſe for Coppers, and under the Oven there muſt be an Aſh-hole, to which there ſhould alſo be another Door, that when the Fire is thoroughly lighted, may be ſhut to prevent the Fuel from burning away too faſt. This Oven ſhould be built with the beſt Materials, otherwiſe it will often want Repairing, which is what ſhould be avoided as much as poſſible, for the Trouble of doing it is pretty great; beſide the often pulling down of the Oven, will impair the other Brick-work into which it is joined.

At the other End of the Stove ſhould be a Door, which ſhould open outward, for the Conveniency of getting into the Stove, which muſt be made of a double Deal, and contrived to ſhut as cloſe as poſſible, to prevent the Air from getting into the Stove to cool it. This Door is alſo of Uſe to open to give Air to the Plants in *Summer*, at ſuch Times, when it may be improper to open any of the Glaſſes. For the better underſtanding of the whole Contrivance, the annexed Plate it is hoped will be ſufficient; ſo I ſhall proceed to deſcribe the other Sort of Stove, with upright Glaſſes in Front.

The Stoves, which are built with upright Glaſſes in Front, are more convenient than the others, as they admit of a ſmall Walk in the Front of the Bark-bed, ſo that the Plants may be eaſier watered, and whenever there is any Thing to be done to the Plants, it may be performed better, as there will be a Paſſage quite round the Tan-bed. The Length of theſe Stoves, may be in Proportion to the Number of Fruit deſired; but they ſhould not exceed forty Feet, unleſs there are two Ovens contrived for Fire to warm them; for one Fire place will not warm a greater Length of Stove, to ſuch a Degree of Heat as is neceſſary to keep the *Ananas* in good Health: therefore, I have choſen to make the annexed Plan of this Length. The Width of this Stove is twelve Feet from out-to-out, the Bark-pit is ſeven Feet over, and the Walk between the Bark-bed and the Front-glaſſes, as alſo at the two Ends, is one Foot broad, which will afford ſufficient Room to paſs round the Bed, to water, or do what is neceſſary to the Plants; the Walk on the Back of the Stove, between the Bark-bed and the Flues, is two Feet broad, which will be commodious enough for any Purpoſes, ſince in theſe ſort of Buildings, their Uſe is chiefly conſulted, for when they are too wide, there requires more Fuel to warm them, and there will be a greater Quantity of Glaſs Work, which is not only an Expence in the firſt Building, but will be an annual Charge to keep in Repair.

The upright Glaſſes in the Front of the Stove are five Feet high, and being raiſed at the Bottom, about ſix Inches above the Walk, will be high enough to admit a Perſon to paſs round to water the Plants; for if theſe Glaſſes are taller, it will render it more difficult to reach the upper Glaſſes to draw them down to admit the Air to the Plants in hot Weather. The ſloping Glaſſes which run up to the Top of the *Stove*, being near twelve Feet in Length, are divided into two Ranges, which will render them more handy to move, and they will be much ſtronger, than if they were only in one Range. From the upper Part of theſe Glaſſes there is a Penthouſe, which ſlopes to the Back of the *Stove*, and projects ſo forward, as to cover the Flues and the back Walk of the Stove; ſo that the Glaſſes will reach as far as the Width of the Tan-bed, to admit Air and Sun to the Plants.

The Oven for this *Stove* ſhould be two Feet ſquare in the Clear, to contain a larger Quantity of Fuel than thoſe of the ſmall Stoves, becauſe the *Stove* being larger, will require a greater Fire to warm it. The Contrivance of the Oven and the Flues is the ſame as in the ſmall *Stove*, ſo need not be repeated here.

Where a Perſon is deſirous to have a large Quantity of Fruit of the *Ananas* every Year, the beſt Way to effect it, will be to have one of each of theſe *Stoves*, the largeſt of them to Fruit the Plants, which if made of the Dimenſion here deſcribed, will contain about two hundred Plants when full grown; and in the ſmall *Stove*, the young Plants may be brought on to ſupply the large *Stove*; which is a much ſurer and leſs troubleſome Method, than to keep the young Plants under Frames without Fire in *Winter*, as is by ſome practiſed.

But thoſe Perſons who may think the Expence too great to build two *Stoves*, may contrive a Frame to raiſe the young Plants in, which if made of Brick-work, may have two Flues carried in the back Wall above the Tan-bed, which may be heated in *Winter* with a ſmall Quantity of Fuel; for as the Frame need not be more three Feet high above the Tan-bed on the Back-ſide, ſo the Quantity of Air contained in ſuch a Frame may be warmed at a ſmall Expence; and as the Glaſſes may be covered with Mats in cold Weather, ſo the Froſt will not cool the Air ſo much as where the Glaſſes have no Covering. If theſe Frames are built on dry Ground, the Bark-pit may be ſunk below the Surface of the Ground, which need not be more than two Feet and a half, and the Wall in Front muſt be about ſixteen Inches above the Ground, but the back Wall muſt be three Feet high, which will make a Declivity ſufficient to carry off the Rain. Upon the Walls muſt be fixed a Plate of Timber, about ſix Inches thick, into which the Gutters on which the Glaſſes are to ſlide muſt be fixed, ſo that the Glaſſes will be raiſed on the Back-ſide, about three Feet and a half above the Surface of the Bark-bed, and about twentytwo Inches in Front, where the ſmalleſt Plants ſhould be plunged, and the largeſt Plants muſt be plunged backward, whereby they will fall in a regular Slope, proportionable to the Glaſſes, ſo that the Plants in every Part of the Bed may be nearly at an equal Diſtance from the Glaſſes.

At one End of this Frame muſt be the Oven for to make the Fire, which ſhould be ſunk entirely below the Surface of the Ground, that there may be a Draught for the Smoak; but this muſt be ſhedded over, to keep out the Rain, and incloſed ſo as to keep out the Wind; for if the Fire is expoſed to the open Air, it cannot be kept regular. Therefore the beſt Method is to carry up the Shed with Brickwork, nearly the Height of the back Wall, which may be covered with Tiles, and have a ſmall Door to it, juſt ſufficient for a Man to enter to put on the Fuel. This Shed need not be above four Feet ſquare, for the Oven ſhould not be more than fourteen Inches ſquare in the Clear, which will contain as much Fuel as is neceſſary to warm this Frame. But this Oven muſt be intirely built in the Shed, and a Cavity carried up from the Bottom, between the Oven and the Bark-bed, otherwiſe the Fire will dry the Tan, and it will be in great Danger of taking Fire, when the Bricks are thoroughly heated.

The Length of the Frame ſhould not be more than twenty-four Feet, and the Width ſix Feet, which will hold a ſufficient Number of young Plants to fill the large Stove, when they are fully grown, and one Fire-place will be ſufficient to warm the Air contained herein. The Flues of this Frame muſt be carried one over the other, in the ſame Manner as in the Stove, the lower Part of the firſt Flue ſhould be raiſed juſt above the Surface of the Bark-bed, to prevent the Heat from drying the Tan. This Flue ſhould be eighteen Inches deep, and ten Inches in Width, and the upper Flue may be fourteen Inches deep, and of the ſame Width. But the better to inform the Reader, I have annexed a Plate of this Frame, by which it will be eaſily comprehended.

Where the Ground is wet, the Bark-pit muſt not be ſunk below Ground, for if the Water ſhould riſe to the Tan in *Winter*, it will cool the Bed, and render it unfit to keep the Plants; therefore in ſuch Situations the whole Pit muſt be raiſed above the Surface of the Ground, which will occaſion the Back-wall to be five Feet and a half high, and the Front-wall three Feet ten Inches high, ſo that it will be more troubleſome to water the Plants, as alſo to ſhift the Tan in theſe Frames, than in thoſe which are low, which is an Advantage always to be taken, whenever the Situation and Soil will admit of it. For the lower the Beds are, the leſs they will be expoſed to Weather, and the more handy will it be to manage the Plants therein.

The Bottom of the Bark-pit in this Frame ſhould be paved with Bricks, or a Foundation of Rubbiſh laid at Bottom, which ſhould be made level and preſſed down hard, to prevent the Earth from mixing with the Tan, which it is very apt to do, where this is not obſerved; beſides, if the Perſons who take out the old Tan, when the Bed requires to be renewed, are not very careful, they will dig into the Ground, and looſen the Earth in the Foundation, ſo that there will always be an Equality therein.

The Stoves and Frame here deſcribed, are chiefly intended for the *Ananas*, or may be uſed for any other tender exotic Plants of low Growth; but whoever is willing to cultivate the larger Sorts of exotic Plants and Trees, muſt build Stoves much higher than either of theſe, otherwiſe the Plants cannot be contained therein; for the *Muſa*, which is now pretty common in *England*, will riſe in the Space of fourteen or fifteen Months, to the Height of twenty Feet or more, provided they are not cramp'd in their Roots; ſo that in order to ſee theſe Plants in Perfection, the Stoves ſhould be at leaſt twenty-five Feet-high, and proportionable in Width.

The moſt magnificent Stoves which have yet been built in *Europe*, are thoſe of the Rt. Hon. Lord *Petre*, at *Thorndon Hall* in *Eſſex*, ſome of which are upward of thirty Feet high, and above twenty Feet broad. The Bark-beds in thoſe Stoves are twelve Feet broad, ſo that there is Room for large Plants to grow in the Borders, which are made in the Middle of theſe Beds; and a ſpacious Walk round the Bed. On the Backſide of the Stove next to the Flues, is a broad Border, in which the ſeveral Sorts of climbing Plants, which are Natives of the warmeſt Countries are planted, and an Eſpalier built to the Top of the Houſe, for theſe to climb againſt, ſo that the Wall is intirely covered with Plants on the Inſide of the Houſe, which make a fine Appearance, becauſe as theſe are not confined in their Roots, ſo they grow as luxuriantly as in their native Soil, and produce their Flowers and Fruit in great Plenty.

In the Building of theſe large Stoves, the ſame Method ſhould be followed, as for the Stove in the ſecond Plate, with no other Alteration but that of inlarging the Dimenſions; which ſhould be in this Proportion, *viz.* for a Stove of twenty-five Feet high, the upright Front Glaſſes ſhould be twelve Feet high, which will allow a good Share of Room for tall Plants near the Front of the Stove, and from the upper Part of theſe Glaſſes, the two Ranges of Sloping Glaſſes are to run to the Top, which will allow a ſufficient Declivity to throw off the Water that may fall on them.

But as theſe Stoves are ſo much longer and broader, than thoſe before deſcribed, ſo there ſhould be two Ovens or Fire-places to each; for as theſe Stoves are deſign'd to contain the tendereſt Plants, ſo the Air muſt be kept above the temperate Heat, as mark'd on the Botanical Thermometers. The Length of theſe Stoves ſhould be fifty Feet, and the Width about eighteen. The two Ovens (or Fire-places) may be built at each End, and ſo the Flues carried to meet in the Middle, but they ſhould have no Communication with each other, for that will prevent their Drawing, ſo that the Smoak will not paſs thro' them freely. The Flues may be carried over each other ſix times, and if the lower Flue is made two Feet and a half deep in the Clear, and the other Flues are each twenty Inches deep, it will raiſe the whole Range about twelve Feet high, including the Covering of each, which will be ſufficient to heat the Air contained in the Houſe; for when the Smoak has paſſed thro' ſix of theſe Flues, there will be no Heat left in it, ſo it will not be of any Service to carry a greater Number of them than can be uſeful; theſe Flues ſhould diſcharge their Smoak at each End, for if the Vents are joined together, it often prevents their drawing well.

As the Culture of the *Anana*, or Pine-apple, hath been of late more generally known, and practiſed in moſt Parts of *England*, ſo there have been many Experiments tried, and ſeveral different Methods uſed to cultivate this Fruit, whereby the Trouble and Expence, which attended this when the Plants were firſt introduced, is greatly diminiſhed. For after the firſt Charge of building the proper Stoves, the Trouble and Expence of cultivating theſe Fruits, is not greater than that for early Melons and Cucumbers; and the Succeſs much more certain; as theſe are not affected by bad Seaſons, or ſpoiled by great Rains, which too frequently deſtroy the Crops of Melons in *England*; ſo that after having been at great Expence and Trouble in raiſing of Melon-plants, and to bring them to Fruit, they are many times totally deſtroyed; or if any of the Fruit remains to ripen, they are rendred ſo watry and ill taſted, as to be unpalatable and unwholſome; whereas the *Ananas*, which do conſtantly remain in the Stove, being protected from bad Weather, are not ſubject to theſe Diſaſters, from the Inclemency of our Climate; and when the Plants are in a good State of Health, the Fruit is generally well flavoured.

One of the moſt conſiderable Improvements, which has been of late made in the Culture of the Pine Apple, is that of planting the Plants (when pretty well grown) into the Tanners-bark out of the Pots. The firſt Perſon who practiſed this, was Mr. *Blackbourn*, a very curious Gentleman in *Lancaſhire*; who has a great Parcel of theſe Plants, and a large Collection of other curious Exoticks, which are in great Perfection. But as I have not been inform'd of his Method of planting the *Ananas*, ſo I ſhall ſet down what I have practiſed, and have found to ſucceed extremely well.

The Suckers or Crowns of the *Ananas*, ſhould be planted in ſmall half-penny Pots, filled with freſh rich Earth, and plunged into the Hot-bed of Tanners-bark, in the ſame Manner as is uſually practiſed, and hath been before directed. During the *Winter* Seaſon they muſt be kept warm, and frequently watered, which will greatly promote their Growth, ſo that a Frame contrived with the Flues in the Back Wall, in the Manner before deſcribed, will be the moſt convenient for raiſing of the young Plants, becauſe they will be kept in the Bark-bed, which is a great Advantage, eſpecially to the young Plants; for as their Pots are ſmall, ſo when they are placed on the Flues of the Stove, or on Shelves, as is commonly practiſed, the Moiſture paſſes away too faſt from their Roots, and the Earth in the Pots ſoon becomes dry, which greatly retards the Growth of the Plants. Whereas when they are plunged in the Tan, the Moiſture which ariſes from the Fermentation, will always ſupply the ſmall Fibres, which are near the Hole in the Bottom of the Pot, with Nouriſhment, and greatly aſſiſt them; and in cold Weather, a ſmall Fire will warm ſo ſmall a Space of Air, as is included in one of theſe Frames.

The Suckers which are planted the latter End of *Summer*, or in *Autumn*, will have filled the ſmall Pots with their Roots, by the middle of *April* following, when the Bark-bed ſhould be renewed, and the Plants ſhaken out of theſe ſmall Pots, and their Roots trimmed, and then planted into penny Pots, filled with light rich Earth as before. Theſe Pots are about ſeven Inches over at the Top, and will be large enough to contain the Plants, until they are planted into the Tan; for when their Roots are confined, the Plants do always make a greater Progreſs, than if they are frequently ſhifted, or planted in large Pots; therefore they ſhould remain unremoved in theſe Pots, till the *Michaelmas* following, obſerving when the Tan declines its Heat, to ſtir it up again, and add ſome freſh Tan to it, which will renew the Heat, and cauſe the Plants to grow vigorouſly; but this ſhould be done in good Weather, that the Plants may not receive any Injury by being expoſed to the open Air. During the *Summer* Seaſon, if the Nights ſhould prove cold, it will be proper to cover the Glaſſes of the Hot-bed with Mats, which will be of great Service to the Plants, by keeping them conſtantly growing; for they cannot grow too freely, ſince the greater Strength they obtain before *Michaelmas*, the larger will be their Fruit. But great Care ſhould be had, not to plunge them too cloſe together at this Seaſon, for that will cauſe them to draw up weak; ſo that their Leaves will be of a great Length, but their Stems will be ſmall, and conſequently their Fruit will be ſo too; ſince it is only ſuch Plants as are large and ſtocky at Bottom, which produce the largeſt Fruit. For which reaſon alſo, the Bark-bed ſhould always be kept up to a proper Height, allowing only Room for the Leaves of the Plants to ſtand under the Glaſſes, without being bruiſed or injured; for when the Bed ſinks, ſo as to leave a large Vacancy between the Plants and the Glaſſes, the Plants will draw up weak, by being too low to receive the Benefit of the free Air, which ſhould be every Day admitted to them in warm Weather, by raiſing of the Glaſſes with Stones, Bricks, *&c.* in proportion to the Warmth of the Seaſon. They muſt be conſtantly watered three or four Times a Week in hot Weather, but the Quantity of Water muſt be proportioned to the Dryneſs of the Earth in the Pots, for ſome Pots will let the Water paſs off much ſooner than others; and ſome of the Plants will imbibe the Moiſture faſter; ſo that when the Earth in any of the Pots appears moiſt, they ſhould not be watered, for which Reaſon, the Plants muſt be carefully obſerved whenever they have Water given to them. In cool or dark Weather, when the Glaſſes of the Hot-bed will not admit of being raiſed to let in freſh Air; the Steam of the Hot-bed, and the Vapours ariſing from the Perſpiration of the Plants, will condenſe to Moiſture againſt the Glaſſes, which will fall in Drops on the Plants, and is often very injurious to them: to prevent which, the Glaſſes ſhould be turned upſide down to dry, or the Moiſture wiped off them in wet Weather, when they cannot be turned. But where a Perſon will be at a ſmall Expence, this Evil may be more effectually remedied, by having Shutters of Bays, or other woollen Cloth placed under the Glaſſes, which will imbibe all the Moiſture which ariſes from the Bed, and ſhould be taken out every Morning, and placed in the open Air to dry, and be put in every Evening, or in cold foggy Days, when there is no Sun-ſhine. Theſe Contrivances I have known uſed with great Succeſs, in raiſing *Cucumbers* and *Melons* very early in the *Spring*; for in thoſe Hot-beds which are made with Horſe-dung, there is always a much greater Steam, than ever ariſes from the Tanners-bark, and this being of a very rancid Nature, is oftentimes deſtructive to theſe tender Plants, eſpecially in moiſt dark Weather, which frequently happens in the *Winter* Months in *England*. But in Stoves or in Frames, where there are Fires, this Vapour being kept rarefied, ſeldom condenſes againſt the Glaſſes in ſuch Quantities as to injure the Plants. Therefore, theſe Shutters (if I may be allowed ſo to call them) are not ſo neceſſary for theſe, eſpecially at ſuch Times when the Fires are continued every Night; but in cold Weather, in the *Spring*, or *Autumn*, when the Fires are diſcontinued, or in ſuch Frames where there is no Conveniency to make Fires; theſe Shutters are of great Uſe, to imbibe the Moiſture ariſing from the Bed.

Theſe Shutters are eaſily made, for there is nothing more required, but to make ſlight Frames (ſomewhat like the ſtretching Frames for Pictures) to fit the Inſide of the Frame, ſo as to lie juſt under the Glaſſes, to theſe Frames ſhould be nailed the Bays, in like manner as is done for Screens, with a Liſt of Tape round the Edges where the Nails are driven, which will ſecure the Bays from being torn by the Nails. The coarſer the Bays which is uſed for this Purpoſe, the more Moiſture it will imbibe, ſo that the Expence will be leſs; but it ſhould not be of a dark or black Colour, becauſe the Rays of Light will be abſorbed by it, to the Prejudice of the Plants. In dark cloudy or foggy Weather, which ſometimes continues for ſeveral Days, in the *Winter* Seaſon, theſe Shutters ſhould be taken out twice every Day, and placed near a Fire to dry; for in the Morning they muſt be taken out to dry the Moiſture from them, which they had imbibed in the Night; and in the Afternoon they muſt be dried again, that they may be put into the Frame dry in the Evening. But as it will be difficult to dry theſe Shutters in damp Weather, ſo it will be proper to have two Sets of them, one for the Night, and the other for the Day; ſo that by ſhifting them alternately, they will have Time enough to be thoroughly dried, and the Bed be conſtantly ſupplied with them, by which Means there will be no Time for the Vapours to condenſe againſt the Glaſſes.

But to return to the Management of the *Ananas* Plants: About the latter End of *September*, or the Beginning of

October, the Plants muſt be planted into the Tan; at which Time there muſt be ſome new Tan provided, in Quantity proportionable to the Size of the Pit; ſo that about half the Tan it will contain ſhould be freſh, which ſhould be well mixed with ſome of the old Tan, and about ten Inches Thickneſs, all of the old Tan, laid on the Top of the Bed, into which the Plants muſt be placed. After the Bed is well mixed, and the Tan levelled on the Surface, which ſhould be raiſed five or ſix Inches above the Level of the Walk, to allow for the ſettling of the Bark; then the Plants ſhould be carefully ſhaken out of the Pots, preſerving a Ball of Earth to their Roots; and after having taken off the decay'd Leaves at the Bottom of the Plants, they ſhould be planted into the Bark-bed, regularly in Rows, about two Feet aſunder, or leſs, according to the Size of the Plants; for if they have Room to ſtand without crowding each other too much, it will be ſufficient, becauſe the Plants will not grow much more in Leaves, but will, ſoon after they have taken Root in the Tan, begin to ſpread open their Hearts, and prepare to ſhew their Fruit; which thoſe that are thus treated ſeldom fail of doing by *Chriſtmas*, or ſoon after; ſo that the Fruit will ripen much earlier in the *Summer* than thoſe which are kept in Pots, becauſe they fruit earlier in *Winter*, and then do not receive any Check in the *Spring*. When theſe Plants are well rooted in the Tan, they will thrive much faſter than thoſe in Pots, and their Roots will extend quite over the Bark-bed, ſo that the Fruit will be well nouriſhed, and the Stems of theſe Fruit being much ſtronger than thoſe in Pots, will ſupport the Fruit much better.

The Plants which are thus planted in the Tan will require leſs Water than thoſe in the Pots, eſpecially in *Winter*, during which Seaſon they need not be watered oftener than twice a Week, and the Quantity given to each Plant ſhould not be more than a Pint; but in the *Summer*, they will require a larger Share of Water, and to be oftener repeated. When the Plants are placed into the Tan, it will be proper to fix down a few Stakes round the Bark-bed, to which a couple of Lines of Packthread may be fixed to ſurround the Bed; the loweſt of which ſhould be about a Foot above the Bark, and the other a Foot above that. The Uſe of theſe Lines is to ſupport the Leaves, ſo as to bear them out of the Walk, that they may not be broken or bruiſed, by Perſons walking near them; which is a much better Method than cutting off the large Leaves, as is moſt commonly practiſed, which is certainly injurious to the Plants, becauſe they not only bleed at the wounded Parts, but do alſo imbibe ſome noxious Damps from the circumambient Air.

As the Plants which are planted in the Tan cannot be removed in the *Spring*, ſo it will be proper to ſtir the Surface of the Bark-bed at that Seaſon; but this muſt be carefully performed with the Hands, ſo as not to break or bruiſe any of the Leaves of the Plants: And if at the ſame Time a little new Tan is added, to raiſe the Surface of the Bed where it may have ſunk too much, it will not be amiſs, provided Care be taken not to raiſe the Tan too high about the Stems of the Plants, which would cauſe the under Leaves of the Plants to decay. During the *Summer* Seaſon they muſt be managed in the ſame Manner as hath been directed for thoſe Plants which are kept in Pots, with this Difference only, *viz.* that they will require leſs Water, and not ſo large a Share of Air; for as the Heat of the Tan will be nearly ſpent before *Summer*, ſo the only Warmth of the Stove will be what is occaſioned by the Heat of the Sun, for I do not approve of making any Fires in the Stoves in *Summer*, unleſs there is an abſolute Neceſſity for it, which can never happen but when the Weather is very bad, and no Sun appears for ſome Days, and then there ſhould be only very ſlight Fires made, and thoſe continued no longer than during the dark Weather; for one Hour's Sun-ſhine, in the *Spring* and *Autumn*, when the Rays are weak, will warm the Air of the Stoves ſufficiently.

There are ſome Perſons who will object to this Method of planting the Plants in Tan, for no other Reaſon, but becauſe they think there ſhould be new Tan added, to renew the Heat of the Bed in the *Spring*, which cannot be practiſed in this Method. But this I am ſatisfied there is no Neceſſity for, from ſeveral Experiments, as well as from the Reaſon of Things; for I have obſerved a much greater Warmth in the Tan, after it has been a whole Year in the Bed, than there ever is in the Earth eighteen Inches below the Surface in the hotteſt Countries where the *Ananas* grow; ſo that if the Air of the Stove is kept ſufficiently warm, there will require no additional Heat to the Roots of the Plants.

As theſe Plants will ripen their Fruit earlier than thoſe in Pots, ſo they will be all of them cut before the Time for bringing the young Plants into the Stove for the ſucceeding Year; therefore the old Stools may be taken out of the Bed, and the Suckers taken off for an Increaſe (if any of them are then remaining on); and if a larger Supply of Plants are wanting, the Stools may be planted into Pots, and preſerved through the *Winter*, which will put out new Suckers the following *Spring*; but where this is not wanted, they may be thrown away.

STRAMONIUM; Thorn-apple.

The *Characters* are:

The Flower conſiſts of one Leaf, ſhaped like a Funnel, and cut into ſeveral Segments; out of the Flower-cup riſes the Pointal, which, when the Flower decays, becomes a roundiſh Fruit, armed for the moſt part with ſharp Thorns, and divided into four Cells formed by a Partition, diſpoſed in the Figure of a Croſs, furniſhed with four Placenta's *or nutritive Membranes, to which ſeveral Kidney-ſhap'd Seeds do adhere.*

The *Species* are;

1. STRAMONIUM *fructu ſpinoſo rotundo, flore albo ſimplici. Tourn.* Thorn-apple, with a round prickly Fruit, and a ſingle white Flower.

2. STRAMONIUM *fructu ſpinoſo oblongo, caule & flore violaceo. Boerh. Ind.* Thorn-apple, with a longiſh prickly Fruit, and Violet-coloured Stalks and Flowers.

3. STRAMONIUM *ferox. Boccon.* Thorn-apple, with very long, ſharp Prickles.

4. STRAMONIUM *Americanum minus, Alkekengi folio. Tourn.* Leſſer American Thorn-apple, with a Winter-cherry Leaf.

5. STRAMONIUM *Malabaricum, fructu glabro, flore ſimplici violaceo. Tourn.* Malabar Thorn-apple, with a ſmooth Fruit, and a ſingle Violet-coloured Flower.

6. STRAMONIUM *fructu ſpinoſo rotundo, flore violaceo duplici vel triplici. Tourn.* Thorn-apple, with a round, prickly Fruit, and Violet-coloured Flowers, which are two or three times double.

There are ſome other *Species* of this Plant which are preſerved in ſome curious Botanick Gardens; but as they have little Beauty or Uſe, ſo I ſhall not enumerate them in this Place. The firſt Sort is uſed to make a cooling Ointment, which is by many Perſons greatly eſteemed. This, tho' not a Native of this Country, yet is now become ſo common upon Dunghills, and other rich Grounds, as not to be eaſily eradicated. The Seeds falling, do continue all the *Winter* in the Ground, and in *Spring* the Plants will come up, and, if ſuffered to ſtand, will ſpread over the whole Spot of Ground, and produce ſuch Quantities of Seeds as to leave a Stock to furniſh the Ground for ſome Years.

The ſecond Sort is not as yet quite ſo common as the former, though it is equally as hardy; and where the Seeds are permitted to fall, the Plants will come up in great Plenty the following *Summer*. This Sort will grow much larger than the former. I have meaſured one of theſe Plants which grew upon a rich Soil upward of ſix Feet high, and divided into many ſtrong Branches, which ſpread almoſt eight Feet Diameter; ſo that 'tis unfit to ſtand in ſmall Pleaſure-gardens, and only to have a Place in ſome outward Part of a Garden or Yard, becauſe it takes up too much Room.

The third Sort is ſomewhat like the former in the Appearance of the Plant, but the Fruit is ſmaller, and beſet with very long, ſharp Thorns; for which Variety it is preſerved in the Gardens of thoſe who are curious in *Botany*.

This *Species* is by ſome ſuppoſed to be the *Dutro* of the *Perſians*, with the Seeds of which they uſe to intoxicate Perſons on whom they have any Deſigns.

This Sort is not quite ſo hardy as the two former, ſo muſt be ſown on a moderate Hot-bed in the *Spring*; and when the Plants are come up, they ſhould be tranſplanted on a new Hot-bed to bring the Plants forward, but you muſt be careful not to draw them too much by keeping the Glaſſes cloſe, which will render them very weak and unfit to ſtand abroad: Therefore after they have taken Root, they ſhould have Plenty of freſh Air when the Weather is warm, and in *May* they ſhould be inured to the open Air by Degrees, into which they may be tranſplanted in *June*, obſerving to raiſe the Plants with a large Ball of Earth, and plant them in a rich Soil, giving them Water until they have taken Root. In *July* theſe Plants will flower, and their Seeds will ripen in *Auguſt*.

The fourth Sort will grow larger than the laſt mentioned. This is preſerved more for the ſake of its long, tubulous, white Flowers, than any other Beauty in the Plant. It is ſomewhat tender, and ſhould be ſowed on a Hot-bed in the *Spring*, and managed as the former; otherwiſe, if the Seaſon proves cold, the Seeds will not ripen; tho' I have ſometimes had Plants of this Kind which came up from Seeds that ſcattered in *Autumn*, and ripened their Seeds very well; ſo that I believe, in a few Years, it may be inured to this Climate, ſo as to thrive with little Care.

The fifth and ſixth Sorts do produce very beautiful Flowers, which afford an agreeable Scent at ſome Diſtance, but if ſmelt to very cloſe, is offenſive to the Head. The Flowers of theſe Kinds are Violet-coloured on the Outſide, but are white on the Inſide; and thoſe of the ſixth Sort have two or three Flowers within each other, in the Manner of the *Primroſe*, which is called *Hoſe in Hoſe*. Theſe two Sorts are much more tender than either of the former, and muſt be ſown early in the *Spring* on a Hot-bed; and when the Plants are come up, they muſt be tranſplanted into a freſh Hot-bed to bring them forward; and as the Heat of this Bed declines, there ſhould be a freſh one prepared, in which ſhould be plunged Pots filled with light, rich Earth, into which the Plants ſhould be placed, obſerving to water and ſhade them until they have taken Root; after which they ſhould have Air given to them, in Proportion to the Heat of the Seaſon, and muſt be often watered, being very thirſty Plants.

Thus they muſt be puſhed on by Heat, in the Manner directed for *Amaranths*; to which the Reader is deſired to turn for their farther Culture. In *July*, if the Seaſon be warm, they may be removed into the open Air, placing them in a warm Situation, where they will produce their Flowers plentifully; and if the *Autumn* be warm, their Seeds will ripen very well; but it will be a ſure Method to preſerve one Plant of each Kind under Glaſſes, leſt thoſe in the open Air ſhould not perfect their Seeds.

STRAWBERRY, *vide* Frigaria.

STRAWBERRY-TREE, *vide* Arbutus.

STYLE: The *Style* of a Flower is a Body accompanying the *Ovary*, either ariſing from the Top of it, or ſtanding as an Axis in the Middle, with Embryons of the Seeds round it.

STYRAX; [takes its Name of *Stiria*, Lat. an *Iſicle*, becauſe a reſinous Matter iſſues, like Drops, out of the Tree. We have many Gums from this Tree: The firſt is the Red *Styrax*; or, as it is called by ſome, the *Jews Frankincenſe*, becauſe they believe it to be that Reſin that the *Wiſe Men* brought and offered to our *Saviour*. This Maſs is rediſh, or yellowiſh, and is extracted out of the Tree by an Inciſion. Another Kind is the *Styrax Calamita*, becauſe in old Times it was tranſported in Pipes of Reeds to preſerve its Odour. This *Styrax* is on the Outſide of a red Colour, and white within, of a ſweet aromatick Scent, very grateful. The third is Liquid *Styrax*, which is an oily, viſcous Subſtance, of the Conſiſtence of an Ointment, of a greyiſh Colour and an aromatick Scent; but this is the product of a different Tree] the Storax Tree.

The *Characters* are;

The Flower conſiſts of one Leaf, ſhaped like a Funnel, and cut into ſeveral Segments; out of whoſe Flower-cup riſes the Pointal, which is fixed like a Nail in the forepart of the Flower; this afterwards becomes a roundiſh, fleſhy Fruit, including one or two Seeds in hard Shells.

We have but one *Species* of this Plant, *viz.*

STYRAX *folio mali cotonei. C. B. P.* Storax-tree, with a Quince-tree Leaf.

This Plant grows plentifully in ſeveral Parts of *Aſia*, from whence it hath been brought into many curious Gardens in *Europe*, tho' at preſent it is very rare in *England*.

It may be propagated by ſowing the Seeds in Pots filled with freſh, light Earth, and plunged into a moderate Hot-bed: This ſhould be done as ſoon as poſſible, when the Seeds are procured; for if they are ſown the latter End of *Summer*, and the Pots kept in a moderate Hot-bed of Tanners-bark all the *Winter*, the Plants will come up the ſucceeding *Spring*; whereas thoſe ſown in the *Spring* do often remain in the Ground a whole Year before the Plants come up.

When the Plants are up, they ſhould be each tranſplanted into a ſeparate ſmall Pot, filled with light, freſh Earth, and plunged into a very moderate Hot-bed, obſerving to water and ſhade them until they have taken Root; after which they ſhould be inur'd to the open Air by Degrees, into which they muſt be removed in *June*, placing them in a warm Situation; in which Place they may remain till the Beginning of *October*; at which Time they ſhould be removed into the Green-houſe, placing them where they may enjoy the Benefit of freſh Air when the Weather is mild; for theſe Plants are tolerably hardy, and do only require to be ſheltered from ſevere Froſt, for in *Italy* they grow extremely well in the open Air, and produce Fruit in great Plenty; from whence I have received a Parcel of the Seeds: But as theſe Plants do grow very ſlowly with us, ſo it would be a good Way to procure ſome from *Italy*, which might be brought over in the *Spring*, packed up in Caſes with Moſs, as is practiſed in bringing over *Orange-trees*, *Jaſmines*, &c. and theſe Plants being well grown before they are brought over, will be more hardy than thoſe raiſed from Seeds here, and will be more likely to produce Fruit.

The *Reſin* of this Tree is brought over for Medicinal Uſe.

I ſhall beg Leave to add another Tree in this Place, which although very different in its Characters from the foregoing, yet as it hath not been ſettled to any particular Genus by the *Botaniſts*, and having long paſſed under the Name of *Storax*, I ſhall continue it by that Name in this Place, having the Authority of Mr. *Ray* for ſo doing.

STYRAX *arbor Virginiana, aceris folio. Raii Hiſt.* The Virginian Storax-tree, with a Maple Leaf, *commonly called* Liquid-amber.

This Tree grows very plentifully in *America*, from whence the Seeds have been brought into *England*, where there has been a great Number of Plants raiſed therefrom, which are found to be hardy enough to endure the Cold of our ordinary *Winters* in the open Air: And it is very probable, as the Trees grow larger, and more woody, ſo they will the better reſiſt the Cold; but while they are young, the tender Branches are very ſubject to periſh with ſevere Froſt.

This Plant may be propagated by ſowing the Seeds in the *Spring* in Pots filled with freſh, light Earth, which ſhould be plunged into a moderate Hot-bed, and duly water'd; when the Plants are come up, (which ſometimes happens in ſix Weeks after ſowing, though often they remain in the Ground until the ſecond Year; in which Caſe, the Earth of the Pots ſhould not be diſturbed until you ſee whether the Plants will come up or not) they ſhould be carefully kept clear from Weeds, and watered frequently; and in *June* they ſhould be removed into the open Air, placing them in a warm Situation, where they may remain until *October*; at which Time they ſhould be placed in a common Hot-bed Frame, where they will be protected from ſevere Froſt: But the Glaſſes being kept off in mild Weather, they may enjoy the free Air.

Towards the latter End of *March*, or the Beginning of *April*, theſe Plants may be taken out of the Pots, and planted into the full Ground: In order to which, a Bed or two of light, freſh Earth ſhould be prepared in a warm Situation, into which the Plants may be planted about a Foot aſunder each Way, which will be full Room enough for them to grow two Years; and being placed ſo cloſe, they may be much eaſier covered, if the *Winter* ſhould prove very ſevere.

When they are planted, the Surface of the Ground muſt be covered with Mulch, to prevent the Wind and Sun from drying the Ground too faſt; and if the Seaſon proves dry, it will be proper to water them now and then until they have taken Root, after which they will require no farther Care but to keep them conſtantly clear from Weeds until *November* following; when it will be proper to lay a little freſh Mulch upon the Surface of the Ground to keep out the Froſt; and if the *Winter* ſhould be very ſevere, the Plants muſt have a little *Peas-haulm*, or ſome Mats thrown over them to protect them from the Froſt.

In theſe Beds the Plants may remain two Years; after which they ſhould be removed in the *Spring* to the Places where they are to remain, or elſe into a Nurſery, where they muſt be planted at a greater Diſtance, ſo as to have Room to grow two or three Years longer. Theſe Trees will grow very vigorouſly after they have ſtood two or three Years; ſo that when their Roots have acquired Strength, they will make great Progreſs in their Growth: With us they will grow to be upward of twenty Feet high, ſo ſhould be placed amongſt Trees of the ſame Growth, and in a warm Situation.

The Leaves of this Tree do ſweat out a liquid Reſin in hot Weather, which when rubbed between the Fingers, emits a fragrant Scent; but I have not ſeen any Flowers produced in *England* as yet.

SUBER; The Cork-tree.

The *Characters* are;

It is in all reſpects like the Ilex, *excepting the Bark of the Tree, which in this is thick, ſpungy and ſoft.*

The *Species* are;

1. SUBER *latifolium perpetuo virens. C.B.P.* The Broad-leafed ever-green Cork-tree.

2. SUBER *anguſtifolium non ſerratum. C. B P.* The narrow-leafed Cork-tree, with ſmooth Edges.

There are ſeveral other Species of this Tree mentioned in ſome of the *Italian* Catalogues of Plants; but the two Sorts here mentioned are all I have obſerved in the *Engliſh* Gardens.

Theſe Trees may be propagated by ſowing their Acorns in the *Spring*, in the Manner directed for the *Ilex*, to which theſe exactly agree in Culture; therefore, to avoid Repetition, the Reader is deſired to turn to that Article for farther Inſtruction.

SUBTERRANEOUS, is that which is under or within the Surface, Bowels, or Caverns of the Earth, or the hollow Places of the Earth that are under Ground.

SUCCORY, *vide* Cichorium.

SUCCULENT PLANTS, are ſuch whoſe Leaves are thick, and abound with Juice.

SULPHUREOUS, is full of Brimſtone.

SUMACH, *vide* Rhus.

SUMMITS, or *Apices* are thoſe Bodies which contain the prolifick Powder, analogous to the Male Sperm in Animals; Theſe generally hang upon the *Stamina* or Threads, which ſurround the *Ovary* in Flowers.

SUN, has uſually been reckoned among the Number of Planets, but he ought rather to be numbered among the fixed Stars.

According to the *Copernican* Hypotheſis, which is now generally received, and which has even Demonſtration on its Side, the *Sun* is the Centre of the planetary and cometary Syſtem; round which all the Planets and Comets, and our Earth, among the reſt, revolve in different Periods, according to their different Diſtances from the *Sun*.

But the *Sun*, tho' eaſed of that prodigious Motion, whereby the Antients imagined him to revolve daily round our Earth; yet is he not a perfectly quieſcent Body.

From the *Phænomena* of his *Maculæ* or Spots, it evidently appears, that he has a Rotation round his Axis, like that of the Earth, whereby the natural Day is meaſured, only ſlower.

Some of theſe Spots have made their firſt Appearance near the Edge or Margin of the *Sun*, and have been ſeen ſome time after on the oppoſite Edge; whence, after a Stay of about fourteen Days, they have re-appeared in their firſt Place, and taken the ſame Courſe over again, finiſhing their intire Circuit in twenty-ſeven Days time; which is hence deduced to be the Period of the *Sun*'s Rotation round his Axis.

This Motion of the Spots is from Eaſt to Weſt; whence it is concluded, that of the *Sun* to which the other is owing, is from Eaſt to Weſt.

Dr. *Hook* thinks it reaſonable to conclude, That the Superficies of the *Sun* is covered with Air, or Atmoſphere, or ſome other fluid Body; and that this Atmoſphere, though poſſibly eighty times thicker than that about our Earth, yet in Compariſon of the vaſt Diameter of the *Sun*'s Body, becomes wholly inviſible to us, though aſſiſted by the beſt Teleſcopes.

He ſuppoſes it alſo to look as bright as the Body of the *Sun* itſelf, and that it is really the Shell of this Atmoſphere, and not the very Body of the *Sun* that ſhines: And from hence he ſays, That all the *Phænomena* of the *Maculæ* and *Fœculæ* of the *Sun* will be ſolved, and that they are only Clouds or Smoaks in this Atmoſphere.

He concludes, That the *Sun* itſelf within this Atmoſphere is a ſolid and opacous Body, from theſe Reaſons:

1. The Conſtancy of its Rotation.
2. The Fixedneſs of its Axis.
3. The Power of its Gravitation or Attraction toward its Centre.

He concludes, That theſe prove its Solidity and Opacity, from the diſappearing of the ſolar Spots in the Limb, and their not returning backwards, as they would ſeem to do if the Body were tranſparent as the Atmoſphere is, or the Flame of a Candle, or the Radiation or hazy Light about the *Nucleus* of a Comet, through which, as well as through its Beard, the ſmall fixed Stars may be ſeen.

He thinks the ſuperficial Parts of the *Sun* to conſiſt of Bodies, ſimilar to our Nitre and Sulphur; and that theſe are ſet on Fire, and conſequently, that the Phyſical Cauſe of its Light is the actual Burning or Fire of its ſuperficial Parts.

Nor can there be any Objection of Moment brought againſt this Hypotheſis, from the Danger of the *Sun*'s Fire being burnt quite out in ſo many thouſand Years as it hath been in Being; for (ſays he) ſuppoſing it to have grown ſome Minutes leſs, ſince it began to give Light, none can contradict it by any Obſervations we have upon Record.

For ſuppoſing we had Aſtronomical Obſervations of 4000 Years ſtanding, as we have none above 2000 of that kind; and allowing that the *Sun*'s Diameter hath been obſerv'd to be as many Minutes as it is now; yet it could not thence be concluded, that the *Sun* did not loſe a Mile in Diameter every Year, and conſequently be now 4000 Miles leſs in Diameter than it then was.

For ſince his Diameter is near 87 times greater than that of the Earth, which latter he ſuppoſes 8000 Miles, then the *Sun*'s muſt be 696000 Miles. Now 4000 is but the 174th Part of the Diameter, and conſequently would have diminiſh'd it but $\frac{1}{8}$ of a Minute, which is a much leſs Quantity than the Ancients pretended to obſerve to.

But ſuppoſing they could have obſerv'd even to Seconds, yet that could not have contradicted it, becauſe it is poſſible the *Sun* may have approached as much nearer us as that Diminution amounts to, and for which, he ſaith, he could ſhew a Reaſon.

Sir *Iſaac Newton* alſo in his *Opticks*, gives good Reaſon to ſuppoſe the *Sun* and fix'd Stars to be great Earths, vehemently hot; whoſe Heat is conſerv'd by the Greatneſs of their Bodies; and the mutual Action and Re-action between them and the Light which they emit, and whoſe Parts are kept from fuming away, not only by their Fixity, but alſo by the vaſt Weight and Denſity of the Atmoſpheres incumbent on them, and every way ſtrongly compreſſing them, and condenſing the Vapours and Exhalations which ariſe from them.

The Light ſeems to be emitted from the *Sun* and fix'd Stars (which probably are *Suns* to other Syſtems) much after the manner as Iron, when heated to ſuch a Degree, as to be juſt going into Fuſion by the vibrating Motion of its Parts, emits with Force and Violence copious Streams of liquid Fire all around: Great Bodies muſt preſerve their Heat *longeſt*, and that, perhaps, in the Proportion of their Diameters.

Sir *Iſaac Newton* hath made it probable, that the great Comet in the Year 1680, in its *Perihelion*, went ſo near the *Sun*, as that it acquired a Heat, which would not intirely go off in 50,000 Years: Whence we may gueſs, that if the *Su* and fix'd Stars be only Collections of denſe and ſolid Matter, like the Planets, but heated to a very intenſe Degree they may be many Millions of Years without loſing any conſiderable Part of their Heat.

According to *Caſſini*, the *Sun*'s Diſtance from the Earth is 172,800,000 *Engliſh* Miles.

As *for the annual Motion of the* Sun *round the Earth*; it i eaſily ſhewn by Aſtronomers, that the annual Motion of th Earth will occaſion ſuch an Appearance. A Spectator in th *Sun* would ſee the Earth move from *Weſt* to *Eaſt*, for th ſame Reaſon that we ſee the *Sun* move from *Eaſt* to *Weſt* and all the *Phænomena* reſulting from this annual Motion, i which ſoever of the Bodies it be, will appear the ſame fro either.

As to the Nature, Properties and Figure of the *Su* &c.

1. As the ſolar Spots are found ſometimes to ſtay thre Days longer behind the *Sun* than they ſpend in paſſing ov the Hemiſphere viſible to us; we eaſily deduce, that the don't adhere to the Surface of the *Sun*, but are at ſome Diſtance therefrom.

2. As the Spots frequently riſe, and vaniſh, even in th Midſt of the *Sun*'s Diſk, and undergo ſeveral Changes, bo with regard to Bulk, Figure and Denſity, it follows, th they frequently riſe, *de novo*, about the *Sun*, and are aga diſſipated.

3. Hence it ſhould follow, that they are form'd out the Exhalations of the *Sun*, and are no other than ſol Clouds.

4. Since then Exhalations proceeding from the *Sun*, riſe bove him, and ſtop at a certain Altitude; it is evident, th is ſome Fluid encompaſſing the *Sun*, to urge the Exhalatio

to riſe; and this Fluid muſt be denſer at Bottom, and rarer at Top, like our Atmoſphere.

5. Since Spots frequently diſſolve and diſappear in the Middle of the *Sun*'s Diſk; the Matter of the Spots, that is, the Solar Exhalations, fall back again to the *Sun*: Whence it follows, that there muſt ariſe various Alterations in the *Sun*'s Atmoſphere, and the *Sun* himſelf.

6. Since the Revolution of the Spots round the *Sun* is found very regular, and likewiſe very near the *Sun*; it follows, that they do not revolve round the *Sun*, but that the *Sun*, together with his Atmoſphere, wherein the *Maculæ* are, move round their common Axis, in an Interval of about twenty-ſeven Days; and hence it is, that the Spots near the Limb, being view'd obliquely, appear narrow and long.

7. Since the *Sun* in every Situation appears like a circular Diſk, its Figure, as to Senſe, muſt be ſpherical, though it is really ſpheroidical.

8. That the Subſtance of the *Sun* is Fire, is thus prov'd: The *Sun* ſhines, and his Rays collected by concave Mirrors or convex Lens's, burn, conſume, and melt the moſt ſolid Bodies, or elſe convert them into Aſhes or Glaſs.

Wherefore, as the ſolar Rays are diminiſh'd by their Divergency in a Duplicate *Ratio* of the Diſtances reciprocally taken, 'tis evident their Force and Effect is the ſame when collected by a burning Lens or Mirrour, as if we were at ſuch Diſtance from the *Sun* where they were equally denſe. The *Sun*'s Rays therefore, in the Neighbourhood of the *Sun*, produce the ſame Effects as might be expected from the moſt vehement Fire; conſequently the *Sun* is of a fiery Subſtance.

Hence it follows, that its Surface is every where fluid; that being the Condition of Flame.

Indeed it is not abſolutely determined, whether the whole Body of the *Sun* be fluid, as ſome think, or ſolid, as others; but as there are no other Marks, whereby to diſtinguiſh Fire from other Bodies, but Light, Heat, a Power of Burning, Conſuming, Melting, Calcining, and Vitrifying, we don't ſee what ſhould hinder, but that the *Sun* may be a Globe of Fire like ours, inveſted with Flame.

9. Since the *Maculæ* are form'd out of the Solar Exhalations, it appears, that the *Sun* is not pure Fire; but that there are heterogeneous Particles mixed along with it.

As for the Diſtance of the *Sun*, Aſtronomers are not agreed; the Reaſon is, that the Determination thereof depends on that of the Parallax, and the Parallax of the *Sun* not being to be found without a long and operoſe Calculation.

Some make the mean Diſtance of the *Sun* from the Earth, 7490 Diameters of the Earth, others 10,000, others 12,000.

The learned *Herman Boerhaave*, treating concerning Fire, ſays we have two vulgarly reputed Sources or Funds of it, *viz.* in the *Sun*, and the *Centre* of the Earth.

For the firſt we have the concurrent Opinions of the Philoſophers of all Ages, except one, who held the *Sun* to be cold.

As to the Central Fire, though our Obſervations do not go ſo far, yet this is manifeſt, that there is an ample Proportion of Fire under-ground; and even that Fire appears much more abundant there than on the Surface; ſo that at leaſt a ſubterraneous Fire muſt be granted.

Thus they who dig Mines, Wells, &c. conſtantly obſerve, that while they are yet but little below the Surface, they find it a little cool; as they proceed lower it grows much colder, as being then beyond the Reach of the *Sun*'s Heat, inſomuch that Water will freeze almoſt inſtantaneouſly; and hence the Uſe of Ice-houſes, &c. But a little lower, about forty or fifty Feet, it begins to grow a little warmer, ſo that no Ice can bear it; and then the deeper they go, ſtill the greater Heat, 'till at length it endangers the Stoppage of Reſpiration, and puts out their Candles.

Morinus, a *French* Author, who had the Curioſity to deſcend himſelf into the Mines of *Hungary*, ſome of which are three or four hundred Fathoms deep, relates, That after he had deſcended about an hundred Fathoms, he came into a very warm Region of the Earth, which laſted to the Bottom of the Mine; being ſo hot both in *Winter* and *Summer*, that the Labourers uſually work without their Cloaths: He adds, That he himſelf was ſcarce able to bear the Heat. He was further told by the Overſeers, that it was univerſal; the lower they deſcend beyond an hundred Fathoms, the hotter it ſtill growing.

Dr. *Boerhaave* adds, That if they venture farther with a lighted Candle, than the Place where it put their Candles out, the Place ſhall be found immediately full of Flame; as once happened in the Coal-Pits in *Scotland*, where a hardy Digger, deſcending to an unuſual Depth, with a Light in his Hand; the Fumes, which are there found very copious, caught Fire thereby (they being no other than Oil or Sulphur greatly rarefied and volatiliz'd by Heat) and burnt the whole Mountain down.

It ſeems as if Nature had lodg'd another *Sun* in the Centre, to contribute on its Part to the giving of Motion to Bodies, and to the promoting of Generation, Nutrition, Vegetation, Germination, &c. of Animals, Vegetables, and Foſſils; and that all Productions, under-ground in particular, as of Metals, Salts, &c. are wholly owing thereto.

How this ſubterraneous *Sun* aroſe may admit of ſome Doubt; whether it were form'd there from the Beginning, like the *Sun* in the Firmament, or gradually produc'd by a ſecondary Collection of vague Fire into this Place.

What pleads in Favour of the former Opinion, are Volcanoes, or burning Mountains, which appear to have exiſted from the firſt Ages: For *Ætna*'s Flames are ſpoke of among the ancient Poets, as even then of great Antiquity; and ſuch Mountains are found in the coldeſt Regions, *viz. Nova Zembla* and *Ice-land*; as well as the hotteſt, as *Borneo*, &c.

As to this, Mr. *Boyle* obſerves, that it cannot be reaſonably pretended, that the ſubterraneal Heat proceeds from the Rays of the *Sun*, ſince they heat not the Earth above ſix or ſeven Feet deep, even in the Southern Countries. And if the lower Part of the Earth were of its own Nature cold, and receiv'd the Heat it affords only from the *Sun*, the deeper Men deſcend therein, the leſs Degree of Heat and Steams they would meet with.

Dr. *Boerhaave* adds, that as to the other Opinion, it is urg'd, that ſuch Source of Fire might have aroſe there in Time, on the Principle of *Gravity*.

For though Fire be by Nature equally diſſeminated every where, yet as we ſhew it to be a Body, and inveſted with the other Properties of Body, it muſt have Weight, and in conſequence thereof muſt have a Tendency towards the Centre.

Hence it muſt be accumulated deep under Ground; and the more ſo, the nearer the Centre, which may be eſteem'd the common Seat or Receptacle it all tends to.

This may receive ſome Confirmation from hence, That the central Space is allow'd to be poſſeſſed by the heavieſt and moſt ſolid Bodies; but we know of nothing to enter the Pores of theſe Bodies, and make them more ſolid than others, except Fire.

Upon the whole, in the firſt View, there ſhould be two great Fires, an upper or *ſolar*, and a lower or *central* one, in all reſpects alike, and the ſame with each other, according to the *Dogma* of *Triſmegiſtus*.

On the ſecond View, the central and ſubterraneous Fire is not original and elementary, but determined and collected Fire; ſuch as we have it on various Occaſions about the Surface.

It may be added, that the denying Vent or Paſſage to this ſubterraneous Fire, appears to be the Cauſe of Earthquakes; thoſe uſually ariſing upon a Vulcano's appearing to be ſtopt up, or ceaſing its Eructations, and going off again upon its opening, or burning afreſh.

Fire may be collected in two manners: Firſt, by a Luminary determining its Rays into a Paralleliſm; ſecondly, by Attrition.

Firſt, Fire is collected when by any Means a Quantity thereof is driven into a leſſer Compaſs; it being Part of the Character of Fire, that it ſpreads itſelf equally; ſo that if left to itſelf, it would be found no more here than there, are conſequently would be inſenſible every where; but if by any Cauſe it be directed toward any certain Part, than it diſcovers itſelf: And ſuch a *Cauſe* is the *Sun*, which revolving with prodigious Velocity around his Axis, directs the impervious Corpuſcles of Fire, every Way in parallel Right Lines, and determines them toward certain Places.

The *Sun* therefore does not produce or emit Fire, but only puts it in Motion in Right Lines, and thus collects it. And hence it is that we perceive Fire ſo long as the *Sun* is above the Horizon; and upon his ſetting, loſe it again; by reaſon, as his Action ceaſes, the Fire again ſpreads itſelf all around.

The *Sun*, according to that excellent Chymiſt, the young *Lemery*, ſeems to be no other than a huge Maſs, or Collection of the Matter of Fire or Light, though placed at ſuch a Diſtance as to diſable it to act on Bodies here on Earth, otherwiſe than by one of theſe two Ways: Firſt, by Emanations or Emiſſions of his own Subſtance tranſmitted hither; but this Hypotheſis being ſubject to great Difficulties, and not ſufficiently anſwering to certain *Phænomena*, Recourſe is had to another, which ſuppoſes Trains of Fire or Light, diſpos'd in all the Interſtices of the grand Expanſe of Air and Æther between the *Sun* and us, and that theſe Trains are made to act on terreſtrial Bodies, by their being vigorouſly driven or impell'd toward ſuch Bodies, by the immediate Action of the *Sun* thereon.

Theſe Trains, in effect, may be eſteem'd as a Sort of little *Suns* prolonged, but always depending on the great *Sun*, as the Source of their Motion and Action on Bodies; 'tis thoſe that form the Rays of Light; they do not, in point of Matter, differ from the Subſtance of the *Sun* himſelf; but only in this, that the ſame thing is more copious in one Caſe than the other.

In the *Sun* we may ſuppoſe the Matter of Light more abundant than the Focus of our largeſt Burning-glaſſes. Thus from the vehement Action of the Rays of the *Sun*, collected in ſuch Glaſs, we learn what Uſe the Air interpoſed between the Rays of Light is of, in tempering their Action, and rendering it more ſupportable; ſince without ſuch Medium, inſtead of warming and illuminating, it would blind and burn us.

So that the Air may be conſider'd as having ſomewhat of the ſame Effect, with reſpect to the Rays of Light falling upon us, that the Water in a *Balneum Mariæ* has. *Mem. de l'Acad. Ann.* 1713.

Omitting to enter into a particular Diſcuſſion about the Matter of the *Sun*, and whether it be Fire, to us it appears very extraordinary, that the *Sun* after a continual Emiſſion of the Corpuſcles of Fire upwards of 5000 Years, ſhould not be yet exhauſted.

The Sun and Stars, according to Sir *Iſaac Newton*'s Conjecture, are no other than great Earths vehemently heated: For large Bodies, he obſerves, preſerve their Heat the longeſt, their Parts heating one another; and why may not great, denſe, and fixed Bodies, when heated beyond a certain Degree, emit Light ſo copiouſly, as by the Emiſſion and Reaction thereof, and the Reflection and Refraction of the Rays within the Pores, to grow ſtill hotter, 'till they arrive at ſuch a Period of Heat as is that of the *Sun?*

Their Parts may be further preſerved from fuming away, not only by their Fixity, but by the vaſt Weight and Denſity of their Atmoſpheres incumbent on them, and ſtrongly compreſſing them, and condenſing the Vapours and Exhalations ariſing from them.

Thus we ſee, that warm Water in an exhauſted Receiver, ſhall boil as vehemently as the hotteſt Water, open to the Air; the Weight of the incumbent Atmoſphere, in this latter Caſe, keeping down the Vapours, and hindering the Ebullition, 'till it has conceiv'd its utmoſt Degree of Heat.

So alſo, a Mixture of Tin and Lead, put on a red-hot Iron, *in vacuo*, emits a Fume and Flame; but the ſame Mixture in the open Air, by reaſon of the incumbent Atmoſphere, does not emit the leaſt ſenſible Flame. *Ibid. Optic.*

But to return to Dr. *Boerhaave*. It is, ſays he, much ſafer to ſay, that the *Sun* has the Power of determining Fire, than that it furniſhes it. The Caſe may be the ſame, as in M. *Villette*'s *Mirror*, which, when expos'd to the naked *Sun*, produces ſuch amazing Effects, and yet has no Effect at all, if the *Sun* be covered from it, by the Interpoſition of a Cloud, or the like: The Mirror may appear the Cauſe of Burning, but it is only an Inſtrument neceſſary thereto; and the *Sun* may be no more.

If now the *Sun* impel the Matter of the Fire in Right Lines, we call it Light, which Light is not any fiery Corpuſcles in the *Sun* itſelf, but the vague Fire above-mentioned, put in a new Determination by the *Sun*, and collected into ſome one Place.

Hence ariſes Heat. For all Heat depends on Fire; nor is it felt, uſeleſs increaſed in proportion to our Senſes, *i. e.* ſo as to be capable of affecting our Organs.

While the *Sun* is above the Horizon he impels all the Rays, before vague and fluctuating toward a Focus; and ſuch Impulſion or Determination is always in Right Lines; ſo that all our Light, Heat, and Colour is the Effect of a rectilinear Motion.

Suppoſe, for Inſtance, a Fire in a dark Place, and a Thermometer placed at a certain Diſtance therefrom, with an Iron Plate between them; in this Caſe the Thermometer will not be affected by the Fire, by reaſon that the rectilinear Paſſage of the Heat is ſtopped. Nor need it be added, that under the like Circumſtances, no Light, Colour, &c. is perceivable; ſo that none of theſe act but in Right Lines.

If there were no *Sun*, nor any Body to ſupply its Place, there would be no Heat, *i. e.* the Fire would not be determined in Right Lines: So that the *Sun* is the Father of all Heat; or ſome other Body that acts in the ſame Manner as the *Sun*: For the *Sun* does not make Heat, but only the Difference between the Heat of the Day and the Night.

The Exceſs of Heat which we feel by Day, is not owing to the Matter of the Fire, but to the *Sun*. For as to the Quantity of Fire, it has been obſerv'd, 'tis the ſame by Night as by Day, and that is the Determination in parallel Lines, that makes the Difference in point of Heat.

Thus no body would imagine, in ſtretching forth his Hand, that it ſhould be preſs'd, as with a huge Weight, both upward and downward, as if pinch'd in a Preſs, and yet there is no Diſpute as to the Fact; and the only Reaſon why he is not ſenſible of it, is, that the Preſſure is equal every Way.

So it is with Fire, which, when equally moved every Way, does not give any ſenſible Heat; but when the *Sun* ſhines, he moves or directs it in Right Lines, and thus renders its Heat perceivable.

As to this, another Author adds; 'Tis not very difficult to conceive how Fire ſhould become ſenſible, either to the Feeling or the Sight, by being thus determined in Right Lines.

By ſuch Determination the vague, fluctuating Corpuſcles are form'd into Rays, and a Train of them driven upon the Organ in a conſtant Succeſſion.

Hence each ſubſequent one ſeconding the Effort of the preceding one, the Impreſſion by ſuch a Series of Augmentations at length is felt. Thus the Air, with which we are every Way ſurrounded, if left at Liberty is not perceived; but if its Parricles be driven or directed in a Stream, whether by a Pair of Bellows, or any other Cauſe that excites a Wind, the Impreſſion it makes will be ſenſible.

Dr. *Boerhaave* adds; It may be doubted therefore, whether the *Sun*, for all his Spots, be a hot Body; ſince, if he were really ſo, he muſt tranſmit us more Fire in *Winter* than in *Summer*.

As to this, *Bacon de forma calida* ſays, It has often been wondered at, why in *Nova Zembla* the *Sun* ſhould never have Power to melt Ice; notwithſtanding that, for the Space of ſome Weeks, his Brightneſs is not leſs conſpicuous than with us.

So the *Dutch*, who wintered in that unhappy Region, expected no leſs, and that in the Month of *July* the Sea ſhould be thaw'd, and they left at Liberty to purſue their Voyage; but were miſtaken. This gave my Lord *Bacon* Occaſion to obſerve, that the *Sun*'s direct Rays have no ſenſible Effect, not even on a level Country; nor yet the reflected Rays, unleſs the Line of Reflection be near that of Incidence, *i. e.* unleſs the Angle intercepted between them be very ſmall; ſo that they may, as it were, ſtrengthen and increaſe the Effect of each other. Now, the more perpendicularly the Rays fall, the ſmaller is the Angle: Hence, in *Nova Zembla*, where they fall extremely obliquely, the Rays by Reflection are ſever'd, and that Effect thus render'd inſenſible.

Dr. *Boerhaave* alſo adds: After the ſame Manner ariſe *Colours*, which are nothing elſe but the Matter of Fire drawn in parallel Lines, without which Motion there would no ſuch thing ever be ſeen.

If now the Particles of Fire, before moveing in a parallel Direction, become determin'd anew in Lines that converge, the Effect of the Fire muſt of Neceſſity be heightened by reaſon a larger Quantity of Fire is, by ſuch Means, collected into one Place.

And were it not that by ſuch Increaſe of Quantity its Particles have a greater Attrition, the Forces of Fire would be proportionable to the Spaces it poſſeſs'd.

But in bringing the Particles ſo near, 'tis impoſſible but they muſt ſtrike on each other; and hence, the nearer they approach, the greater and quicker the Attrition; and a briſk Attrition does collect Fire of itſelf.

If then the Quantity of Fire in any Place be increaſed, *e. g.* ſix-fold, the Attrition will of conſequence be augmented proportionably thereunto.

Some maintain, that Fire acts with more Force as the Reſiſtance of the *Medium* is leſs; but the contrary is true; for Fire would be incapable of warming, unleſs either reflected or collected.

The Heat would be never the greater for the *Sun*'s acting on the Fire, unleſs in its Progreſs it were either refracted or reflected, and by that Means determined to one Place more than to another.

And hence it is, that the Cold *cæteris paribus*, is always greateſt in ſtill Weather; and that in the Severity of *Winter*, and particularly froſty Weather, the Heavens are clear.

Thus alſo the Tops of the talleſt Mountains, where the Reflection and Refraction are leſs conſiderable, by reaſon of the want of Clouds, are eternally cover'd with Snow; as in *Peru*, *Mexico*, the *Alps*, &c. And to the ſame Cauſe it is owing, that the Nights in *Armenia* are ſhivering cold.

In the mountainous Places in theſe Countries, we are told, there is no ſuch thing as pure Water, but all Ice.

Plants make a Shift to grow about the Feet of the Mountains, but higher up no Vegetable can live; not for want of Food, but through the Intenſeneſs of the Cold; Men, ſtaying there but a little Time, catch violent Agues, which, with a longer Stay, grow incurable.

Heat then depends not upon the Fire's being ſent or determined toward us, but only by its being reflected, either by Mountains or Clouds.

If Fire be propagated through an uniform *Medium*, it will never produce any conſiderable Heats.

And hence it is that the Degree of Heat is not ſo very intenſe in the Torrid Zone, as one would otherwiſe expect; but that in the Iſland of *Ormus* 'tis perfectly ſcorching, and not endurable by any Mortal, unleſs they were to ſcreen themſelves under Water.

The Heat here is ſaid to be ſo vehement, that People, like Fiſhes, are forced to ſleep in Ciſterns of Water, with only the Head out, which is kept ſuſpended by a Contrivance for that Purpoſe: The Caſe is, that the ſaid Iſland is full of Salt Rocks, which act like ſo many *Specula*, and reflect the Light in great abundance; ſo that the Iſland at a Diſtance appears like one continued Fire.

Another Cauſe which ſome alledge for this exceſſive Heat is, that the Iſland was anciently full of white Mountains, which having in Time been all laid level, the whole Surface of the Iſland is white, and thus diſpoſed to reflect abundance of Light.

Heat therefore does not immediately depend on the *Sun*, but on Bodies that reflect. Hence in high Places, and where the Atmoſphere is very rare, the Heat is extremely feeble, and *vice verſa*.

But it remains here to be obſerved, that according as the Direction of the *Sun*'s Rays is greater or leſs, greater or leſs Heat is produced. For,

1. A Body ſtriking perpendicularly on another, acts on it with all its Force.

2. A Body ſtriking obliquely againſt another, acts with the leſs Force, the more it deviates from the Perpendicular.

Now Fire directed by the *Sun* into Right Lines, muſt obſerve the ſame mechanical Law as other Bodies, and conſequently its Action muſt be meaſured by the Sine of the Angle of Incidence.

And hence Fire ſtriking on any Obſtacle in a Direction parallel thereto, has no ſenſible Effect, by reaſon the Proportion is almoſt infinite, *i. e.* nothing.

Accordingly Dr. *Halley* obſerves, that the *Sun* radiating on the Earth in the Morning has but little Effect, but that when raiſed to the Meridian he acts with all his Force.

Now this is owing to the Atmoſphere, which being replete with an infinite Number of Corpuſcles, reflects more of the *Sun*'s Rays to the Earth, when they fall perpendicularly, than would otherwiſe arrive there. For whereas falling obliquely, they would be reflected, and thus be thrown off, and diſperſed into other Parts; now that their Incidence is perpendicular, they will paſs directly through.

And hence ariſes what is frequently obſerved by Sailors, viz. That when the *Sun* radiates obliquely upon the Sea, as in the Evening, there is no enduring his Rays; by reaſon they are all reflected from the Water, and ſcarce any loſt therein: So that the Rectitude or Obliquity of the Rays contribute very conſiderably to the collecting of Fire.

And this obliquity, &c. is to be conſidered in a two-fold reſpect, both with reſpect to the Matter in the Atmoſphere, nd to the Surface of the Earth.

Now Heat may be varied two Ways.

1. By means of the Atmoſphere; for this does not always emain the ſame. Thus, *e. g.* Water is naturally tranſpa-ent, and if you warm it, it ſtill retains its Tranſparency; ut if you make it boil, the Vapour iſſuing from it, though erhaps a Million of times rarer than the primitive Water, ill not be tranſparent, but opaque, by reaſon its Parts now e in a different Arrangement.

And hence thoſe Legions of Corpuſcles every where float-g in the vaſt Receptacle of the Atmoſphere, whenever ey acquire a different Diſpoſition, which they frequently , alter the Collection of the Rays on the Earth. Add, at thoſe white Clouds which appear in *Summer-time*, are, it were, ſo many Mirrors, and occaſion exceſſive Heat.

Theſe cloudy Mirrors are ſometimes round, ſometimes ncave, polygonous, &c. When the Face of the Heaven covered with ſuch white Clouds, the *Sun* ſhining among em muſt of Neceſſity create a vehement Heat, ſince many his Rays, which would otherwiſe perhaps never touch our rth, are hereby reflected to us; thus if the *Sun* be on one e, and the Clouds on the oppoſite one, they will be perfect Burning-glaſſes. And hence the Phænomena of Thunder, &c.

I have, ſays Dr. *Boerhaave*, obſerv'd a kind of hollow Clouds full of Hail and Snow; during the Continuance of which the Heat was extreme; ſince by ſuch Condenſation they were enabled to reflect much more ſtrongly: After this came a ſharp Cold, and then the Clouds diſcharged their Hail in great Quantity; to which ſucceeded a moderate Warmth. Frozen, concave Clouds therefore, by their great Reflections, produce a vigorous Heat; and the ſame when reſolv'd, exceſſive Cold.

Hence it is probable, that Thunder is only produc'd when ſuch concave Clouds, before convolved into ſpherical Figures, are driven with oppoſite Motions againſt each other; and the Rays tranſmitted through thoſe Spheres from burning *Foci*.

All Clouds, 'tis probable, contain Snow and Ice, but theſe in their Fall through the warmer Regions of the Atmoſphere nearer the Earth, liquify and diſtil in Drops.

The Meteors in the Atmoſphere have likewiſe their Share in reflecting of Fire. Theſe, in effect, are a Sort of wandering Fire, viſible by Night, and which determine the Fire over and upon the Earth.

2. It is varied by means of the Earth: For as the Surface of the Earth varies, ſo muſt the Heat. Thus ſandy Places, reflecting more Rays than others, muſt excite a greater Degree of Heat.

On the higheſt Mountains we always find the moſt Cold, Snow, and Hail.

In the ſultry Region of *Peru*, the Mountains are all *Summer* long cover'd with Snow, by reaſon they only receive direct, and but little refracted Fire; and the Effect of Fire ariſing merely from being determin'd by the *Sun* into a Paralleliſm, is found, by Computation to be very inconſiderable. For this Effect, as already obſerv'd, is greater in *Winter* than in *Summer*.

Though the *Sun* be in his Apogee in the *Summer*, and in his Perigee in *Winter*, yet will a Night's Ice bear its ſhining upon it five or ſix Hours ere it be thaw'd.

And if as the *Sun* riſes nearer toward the Zenith, the Ice and Snow at length begin to run, this is not owing to the greater Force of the *Sun*, but to the greater Reflection and Collection of his Rays from the Circumſtances and Poſition of the Atmoſphere and Earth.

But the higheſt Tops of Hills are always free from Snow; the Reaſon whereof is, that Water, *i. e.* the Vapours and Exhalations emitted therefrom, never riſe by the *Sun*'s Action above a Mile high. But there are Mountains a Mile and a half high; to the Tops of theſe therefore, Vapour, and conſequently Clouds, can never mount.

And hence it is, that in very high Mountains, as the *Pico de Theide* in *Bohemia*, tho' the middle Part be eternally inveſted with Ice and Snow, and the Bottom ſcorch'd with intolerable Heat, yet on the Top you find yourſelf in a pure, thin, ſerene Air, and view the Clouds hovering at a conſiderable Diſtance below you. Hence alſo it is, that all Thunder is confined within leſs than a Mile's Height.

Add that in Caverns, and the hollow Parts under-ground, the Heat is very great; ſo that the Air is coldeſt in the higheſt Places, and hotteſt in the loweſt; but in the intermediate Atmoſphere very unequal.

Heat therefore depends on Clouds, Mountains, &c. which reflect the Light variouſly, and on the Direction of the *Sun*'s Rays, or the Poſition of his Body with reſpect to us.

Hence again we gather, that Fire is the univerſal Cauſe of all the Motions about our Earth; for all Fluidity depends on Fire; and accordingly in the large Burning-glaſſes the firmeſt Bodies become fluid, and evaporate in Fume: And the more fluid any Body is, the more Fire it contains; whence it is, that Water depriv'd of all its Fire, fixes into Ice, and when expos'd afreſh to the Fire, reſolves into Water; and all Fluids whatever, if deſtitute of Fire, would do the ſame.

Thus far the Learned *Boerhaave*.

The *Sun* (ſays a certain Author) may be accounted the *Parens Naturæ*, or the *Primum Mobile* of all vegetative Motion.

The *Sun*'s attractive Virtue is very conſpicuous, in the Exhalation of thoſe crude and unwholeſome Vapours, with which the Earth is often infeſted; which, if they were ſuffer'd to continue long upon the Face of the Earth, would render it a miſerable Deſert.

The *Sun*, by ſubliming thoſe crude and hurtful Vapours, and their being rarefied before their Deſcenſion and Diſtribution, forms them into Rain, which is of great Conſequence in Vegetation.

To this he adds, the Attraction of Plants themſelves, which creates a kind of Emulation in them, which ſhall grow the talleſt.

But that which the Antients did uſe to attribute to Attraction, may now be very well ſolved by Pulſion. To apply which to the Matter in Hand: When the Surface of the Sea, *&c.* is divided by the Heat of the *Sun*, and the Power of the Air, their Aſcenſion through the Atmoſphere, either by the Rarefaction of the Air by the *Sun*, or otherwiſe by the Reſpiration of the Terraqueous Globe, which in this Caſe may be ſuppoſ'd to act like the Body Natural; or elſe that the Air being rarefied by the *Sun* Beams, does, by the Gravitation of his own Body in general, force thoſe humid Vapours by Pulſion upwards, through thoſe Beams or Rays of Light, which are, as it were, ſo many Pipes or Tubes for their ready Paſſage, Aſcenſion, and Conveyance.

Or if thoſe Vapours are convey'd by the Undulation of the Air in a perpendicular Manner, rather than a radient one, through the Rays and Beams of Light, which ſoever of theſe Ways it is, the *Sun* is the principal Agent in this Buſineſs; and the whole Proceſs is either Attraction, Pulſion, or Reſpiration, forwarded by the virtual Power of it.

That the Rarefaction of the Air by Heat is a great Help to Attraction or Pulſion, may be diſcovered by the Fire-Engine made by Mr. *Savory*; we cannot ſay that the Water is either forced or attracted by the Heat, but that the Air that is in the Pipe is lighten'd by its rarefying Quality to ſuch a Degree, that the *Æquilibrium* is loſt, and the Impulſe and Preſſure of the Air, which is without, forces the Water to that great Height that is ſeen in the Operation.

And ſo, if a little Scrip of Paper burning and fuming be put into a common Drinking-glaſs, and it be turned up immediately, and put upon a Plate of Water, it ſeems as tho' it would ſuck it up into the Glaſs; when indeed, the Truth of the Experiment is, that it is only the outward Preſſure and the inward Weakneſs of the Air to reſiſt, being purified by Heat: For if the ſame Glaſs ſhould be plung'd into a Baſon of Water up to the Foot of it, yet the Water that is in the Baſon would not enter into the Glaſs till the Air, either having loſt its own Strength, or rather inſinuated or incorporated itſelf in the Water, loſes its own Strength; ſuch is the Force of Air.

But this may ſuffice concerning what the Antients call *Attraction*, which in many Caſes is ſolv'd by *Pulſion*, or the Preſſure and elaſtick Power of the *Air*, rather than by the attractive Power of the *Sun*.

It is ſufficiently prov'd by ocular Demonſtration, that the Vapours of the Sea, Rivers, Lakes, and all the Humidities of the Ground, are drawn up after this manner.

And that Heat is an Agent in this Operation, has been clearly prov'd by the Experiments of that learn'd Naturaliſt Dr. *Halley*; by taking a Veſſel of Water four Inches deep, and ſeven, and nine Tenths in Diameter; which being warm'd to ſuch a Degree, as it might be ſuppos'd the Air may do it, in ſome of the hotteſt Months; and letting it ſtand about two Hours time, and weighing it, found it had evaporated near half an Ounce; altho' there did not appear any Reek or Smoak, nor did the Water ſeem warm, by putting his Finger into it; from which it may be concluded, that out of that ſmall Superficies of the Water, ſix Ounces would be evaporated in the Space of twenty-four Hours.

Upon this Suppoſition, every ten ſquare Inches of the Surface of Water, yield in Vapour *per* Day a Cube Inch of Water; and each ſquare Foot half a Wine Pint; and every Space of four Feet ſquare, a Gallon; a Mile ſquare 6914 Tun; a ſquare Degree ſuppoſe of 69 *Engliſh* Miles will evaporate 33 Millions of Tuns.

This will account for the *Caſpian* Sea being always at a Stand, and neither waſting nor overflowing; and alſo for the Current ſaid to ſet always in at the *Streights* of *Gibraltar*, notwithſtanding that thoſe *Mediterranean* Seas receive ſo many, and ſo conſiderable Rivers.

This Experiment has been carry'd yet farther by the *Oxford* Society; who, ſuppoſing a cubical Foot of Water to weigh 76 Pounds, and this Foot containing 1728 cubick Inches, and divided in the 76 Pounds, gives half an Ounce and $13\frac{1}{3}$ Grains, which is the Weight of a cubical Inch of Water; therefore the Weight of the 233 Grains is $\frac{233}{253\frac{1}{3}}$, or 35 Parts of a cubick Inch divided by 38.

Then the Area of a Circle, the Diameter of which is 7 Inches and upwards, is more than 49 ſquare Inches; which if it be divided by $\frac{35}{38}$ Parts of an Inch, the Quantity of Water carry'd off in Vapours, the Product will be $\frac{35}{1862}$ or $\frac{1}{53}$ Parts of an Inch, waſted in that Experiment. This is a plain Proof of what a great Quantity of Water may be thus carry'd off, in great Dimenſions of Water, even enough to ſupply all Rains, Dews, *&c.*

But the *Sun* beſides this has a diffuſive Power, (not to dwell on the Light it conveys to theſe ſublunary Regions) without which the whole Race of Mankind muſt wander and grovel in the Dark; for by its genial and chearful Rays, it exhilarates the vegetable Part of the Creation, and makes Nature herſelf to ſmile.

It has an Influence upon deep Grounds, by warming and chearing the Pores of the Earth, when dilated and ſodden by too much Wet, and puts the emulgent Fibres of Plants upon ſeeking their Food.

It helps the Surface of the Ground by attracting or diſpelling the Vapours, which would otherwiſe make it noxious: But more particularly it warms and heats the Ground, and by its powerful Influence, contributes to diſſolve the latent Salt, and prepares them for being ſucked in by the Fibres of the Palnts, which by the ſame genial Force are put in Action to ſeek out for their Food.

The *Sun* alſo exhales all ſuperfluous Moiſture, and by its vital Heat comforts the dilated Pores.

The *Sun* diffuſes the early Dews, which, if they lay too long on Plants, would rot rather than refreſh them: It alſo preſſes them into the Nerves, and other analogous Parts. This influential Power operates on the Boughs, Branches, Leaves and Fruit.

The *Sun* alſo qualifies the Air; which otherwiſe by its Frigidity would ſtop the very Courſe of Nature. And indeed it would be difficult to inſtance any thing in the whole Circle of *Botanology* that does not participate of a Share of this virtual and diffuſive Good.

From what has been ſaid, we may eaſily account for the Difference of Heat in *Summer* and *Winter*, *viz.* from the Obliquity of the *Sun*'s Rays: This therefore ſhould be well conſider'd in the Contrivance of *Stoves*, to preſerve the moſt tender Exotick Plants, which ought to have their Glaſſes ſo ſituated as to receive the *Sun*'s Rays in direct Lines as great a Part of the Year as poſſible: For which Reaſon the Stoves which have upright Glaſſes in Front, and ſloping Glaſſes over them, are juſtly preferred to any at preſent contriv'd. And from hence we ſee the Advantage of making the back Part and Ceiling of all Greenhouſes and Stoves as white as poſſible, ſince it is evident that the Rays of Light are hereby reflected with much greater Force, and ſo conquently the Heat is greatly increas'd, which ſhould always be obſerved in Buildings of this Kind.

From hence alſo we may learn, that Countries in the ſame Latitude may be very different in their Heat, according to their Situation in reſpect to the *Sun*'s Rays, or according to the Nature of the Soil in reflecting the Rays with a greater or leſs Force: So that in preſerving Exotick Plants, the Heat which they require can't be exactly determin'd from the Latitude of the Places of their Growth: But the Situation of the Places muſt alſo be conſider'd, as whether they grew on Hills, Mountains or Vallies; and if on the Side of Hills, which Side in reſpect to the *Sun*; with ſeveral other Obſervations which ought to be made by ſuch as collect Plants in foreign Countries.

I ſhall here add a Table of the Shadow of the *Sun* at the ſeveral Seaſons of the Year, which was communicated to me by Mr. *Timothy Sheldrach* of *Norwich*; by which a Perſon may more readily ſee what Effect Walls, Buildings, *&c.* have in ſhading the Ground to ſeveral Diſtances, according as the *Sun* is more or leſs elevated above the Horizon; as alſo how great the Shade will be in Green-houſes as the Piers are in Breadth, or the Wall in Front is in Height below the Saſhes.

The firſt three Tables ſhew the Length of Shadows in the *Summer* and *Winter Solſtice*, and in the *Vernal* and *Autumnal Equinoxes*. Suppoſe a Mountain, Column, or other Body, whoſe perpendicular Height is one Degree; the Length of the Shadow from any Thing of that Altitude is here ſhewn in every Degree of Latitude, at the above-mentioned times, in Degrees and Minutes: And where a ſhorter Meaſure than a Mile is required, it is ſhewn in Seconds. The fourth Table is calculated for the Latitude of 51° 30′, which is pretty near that of *London*. This fourth Table ſhews the Length of the Shadow made by any perpendicular Body of five Feet Altitude on a Plane, at the Time the *Sun* enters every Sign of the *Zodiack*, which at a South *Sun* will be found very exact on a true Level.

SUPERFICIES of the Ground, &c. is the outward Part or Surface of it.

SURFACE, is the bare Outſide of a Body or Superficies.

SURIANA.

The *Characters* are;

It hath a Roſe-ſhaped Flower, conſiſting of ſeveral Petals, which are placed in a circular Order, from whoſe Empalement ariſes the Pointal, which afterwards becomes the Fruit, which generally conſiſts of four Capſules, in which are included four roundiſh Seeds.

We know but one *Species* of this Plant, *viz.*

SURIANA *foliis portulacæ anguſtis. Plum. Nov. Gen.* Suriana, with narrow Purſlain Leaves.

This Plant was ſo named by Father *Plumier*, who diſcovered it in the *French* Settlements in *America*, in Honour to Dr. *Joſeph Surian* of *Marſeilles*, who was a very curious Botaniſt.

The Seeds of this Plant were brought from the *Havanna*, by the late Dr. *William Houſtoun*, who found the Plants growing there in great Plenty on the Shore, in moiſt Places where the Salt Water uſually flows. It alſo grows plentifully in ſome Parts of the Iſland of *Jamaica*.

It is propagated by Seeds, which muſt be ſown on a Hot-bed early in the *Spring*, and when the Plants are come up, they muſt be carefully cleaned from Weeds, and frequently refreſhed with Water. In warm Weather the Glaſſes of the Hot-bed ſhould be raiſed every Day, to admit freſh Air to the Plants, to prevent their drawing up too weak. When the Plants are fit to tranſplant, they ſhould be taken up carefully, and each planted in a ſeparate ſmall Pot, filled with freſh light Earth, and plunged into a Hot-bed of Tanners-bark, obſerving to ſhade them until they have taken new Root; after which Time they muſt be duly watered every Evening in hot Weather, and they muſt have freſh Air admitted to them every Day in Proportion to the Warmth of the Seaſon. In this Hot-bed the Plants may remain till the Autumn, when the Nights begin to be cold, at which Time they ſhould be removed into the Stove, and plunged into the Bark-bed. During the *Winter* Seaſon theſe Plants muſt be kept warm, eſpecially while they are young, otherwiſe they will not live through the *Winter* in this Country; they muſt alſo be frequently refreſhed with Water, but it muſt not be given to them in large Quantities in cold Weather, for too much Moiſture in *Winter* will ſoon deſtroy them. Theſe Plants do make but ſlow Progreſs the firſt Year, but afterwards they will grow pretty freely, if they are not ſtunted in *Winter*. They muſt be conſtantly kept in the Stove in this Country, and if they are plunged into the Bark-bed, they will make the greater Progreſs. In *Summer* they muſt have a large Share of Air, by opening the Glaſſes of the Stoves, and if their Leaves are covered with Filth (which the Plants in Stoves do often contract) they ſhould be carefully waſhed with a Sponge, otherwiſe the Plants will not only appear unſightly, but it will retard their Growth.

Theſe Plants do uſually grow about ſeven or eight Feet high, and as they retain their Leaves throughout the Year, ſo they afford an agreeable Variety amongſt other Plants in the Stove.

SYCAMORE, *vide* Acer Majus.

SYMPHYTUM: [Some derive it from σὺν, *with*, and φύω, to *grow to*, becauſe this Plant is conſolidating and vulnerary, and of great Uſe in cauſing Fleſh to grow again: Others derive it of συμφυεῖ, to *conglutinate*, becauſe if the Leaves or Roots of this Plant are boiled with Fleſh, the Fleſh returns again into one Maſs; hence it is called *conſolida major officinarum*] Comfrey.

The *Characters* are;

The Flower conſiſts of one Leaf, ſhaped like a Funnel, having an oblong Tube, but ſhaped at the Top like a Pitcher; out of the Flower-cup (which is deeply cut into five long, narrow Segments) riſes the Pointal, attended with four Embryo's, which afterwards become ſo many Seeds, in Form ſomewhat like the Head of a Viper, and do ripen in the Flower-cup.

The *Species* are;

1. SYMPHYTUM *conſolida major fœmina, flore albo vel pallide luteo. C. B. P.* The greater Female Comfrey, with a white or pale-yellow Flower.
2. SYMPHYTUM *conſolida major mas, flore purpureo. C. B. P.* The greater Male Comfrey, with a purple Flower.
3. SYMPHYTUM *majus, tuberoſa radice. C. B. P.* Greater Comfrey, with a tuberoſe Root.
4. SYMPHYTUM *minus tuberoſâ radice. C. B. P.* Smaller Comfrey, with a Tuberoſe Root.
5. SYMPHYTUM *Echii folio ampliore, radice rubra, flore luteo. Inſt. R. H.* Comfrey, with a broad Vipers-bugloſs Leaf, a red Root, and a yellow Flower.
6. SYMPHYTUM *Echii folio ampliore, radice rubra, flore exalbido. Inſt. R. H.* Comfrey, with a broad Vipers-bugloſs Leaf, a red Root, and a whitiſh Flower.
7. SYMPHYTUM *Echii folio anguſtiore, radice rubra, flore luteo. Inſt. R. H.* Comfrey, with a narrow Vipers-bugloſs Leaf, a red Root, and a yellow Flower.
8. SYMPHYTUM *Creticum, echii folio anguſtiore, longiſſimis villis horrido, flore croceo. Tourn. Cor.* Candy Comfrey, with a narrow Vipers-bugloſs Leaf, covered with very long Hairs, and a Saffron-coloured Flower.
9. SYMPHYTUM *Orientale, echii folio ampliore, longiſſimis villis horrido, flore croceo. Tourn. Cor.* Eaſtern Comfrey, with a broad Vipers-bugloſs Leaf, covered with long Hairs, and a Saffron-coloured Flower.
10. SYMPHYTUM *Orientale, echii folio, flore albo, tenuiſſimo. Tourn. Cor.* Eaſtern Comfrey, with a Vipers-bugloſs Leaf, and a very narrow white Flower.
11. SYMPHYTUM *Orientale, echii folio minore, flore nunc albo nunc flaveſcente. Tourn. Cor.* Eaſtern Comfrey, with a ſmaller Vipers-bugloſs Leaf, and a Flower ſometimes white, and at other times of a yellowiſh Colour.

12. **Symphytum** *Orientale oleæ folio, argenteo, flore flaveſcente. Tourn. Cor.* Eaſtern Comfrey, with a ſilvery-olive Leaf, and a yellowiſh Flower.

13. **Symphytum** *Orientale, anguſtifolium, flore cæruleo. Tourn. Cor.* Eaſtern Comfrey, with a narrow Leaf and a blue Flower.

14. **Symphytum** *Conſtantinopolitanum, borraginis folio & facie, flore albo. Tourn. Cor.* Conſtantinople Comfrey, with the Leaf and Face of Borage, and a white Flower.

15. **Symphytum** *Orientale, folio ſubrotundo aſpero, flore cæruleo. Tourn. Cor.* Eaſtern Comfrey, with a rough, roundiſh Leaf and a blue Flower.

16. **Symphytum** *Orientale, folio ſubrotundo aſpero, flore cæruleo odoratiſſimo. Tourn. Cor.* Eaſtern Comfrey, with a rough roundiſh Leaf, and a very ſweet blue Flower.

The firſt Sort grows wild upon the Sides of Banks and Rivers in divers Parts of *England*, where it is commonly gathered to ſupply the Markets for Medicinal Uſe. The ſecond Sort is ſometimes found wild in *England*, but is leſs common than the former; in *Holland* it is the only Sort I obſerved wild, where it grows in great Plenty on the Sides of the Canals almoſt every where.

The third Sort I never yet obſerved growing wild, but it is preſerved in many Gardens for Variety.

All theſe Plants may be cultivated, either by ſowing their Seeds in the *Spring*, or by parting of their Roots; the latter Way, being the moſt expeditious, is chiefly practiſed where they are planted for Uſe. The beſt Seaſon for parting their Roots is in *Autumn*, at which Time almoſt every Piece of a Root will grow: They ſhould be planted about eighteen Inches aſunder, that they may have Room to ſpread, and will require no farther Care but to keep them clear from Weeds, for they are extreme hardy, and will grow upon almoſt any Soil, or in any Situation.

The fourth Sort is pretty common in ſeveral *Engliſh* Gardens, where it is preſerved for the Sake of Variety: This increaſes pretty faſt by its Roots, ſo is ſeldom propagated by Seeds. The fifth, ſixth and ſeventh Sorts grow wild in *Spain* and *Portugal*, from whence their Seeds may be obtained; theſe have red Roots, ſomewhat reſembling thoſe of the *Alkanet*, and are by ſome Botaniſts ranged amongſt the *Alkanets*.

The other Sorts were diſcovered by Dr. *Tournefort*, in the *Levant*, from whence he ſent their Seeds to the Royal Garden at *Paris*. Theſe are all of them pretty hardy Plants, ſo may be propagated by ſowing their Seeds on a Bed of freſh, undunged Earth, in the *Spring* of the Year, and when the Plants are come up, they ſhould be carefully cleared from Weeds, and where they are too cloſe, they muſt be thinned, ſo as to allow them four or five Inches Diſtance from each other; and the following *Michaelmas* they may be tranſplanted where they are deſigned to remain, which ſhould be in freſh undunged Earth, at about two Feet Diſtance from each other, where they may remain to flower and ſeed.

SYRINGA; [ſo called of σύριγξ, a *Pipe*, becauſe the Branches of this Shrub, the Pith being taken out, may ſerve for making Pipes for Syringes] The Mock-orange, *vulgo*.

The *Characters* are;

The Flower, for the moſt part, conſiſts of five Leaves, which are placed circularly, and expand in form of a Roſe; from whoſe Flower-cup riſes the Pointal, which afterwards becomes a roundiſh Fruit, adhering to the Flower-cup, divided into four Cells, which are full of ſmall Seeds.

The *Species* are;

1. **Syringa** *alba, ſive Philadelphus Athenæi. C. B. P.* The common white Syringa or Mock-orange.
2. **Syringa** *flore albo pleno. C. B. P.* The double white Syringa.
3. **Syringa** *flore albo ſimplici, foliis ex luteo variegatis.* The ſtrip'd-leafed Syringa.
4. **Syringa** *nana nunquam florens.* The Dwarf Syringa.

The firſt Sort is very common in moſt *Engliſh* Gardens, but the ſecond is not quite ſo plenty, though, indeed, it is a Variety ſcarce worth obſerving, ſince the Flowers are always ſingle where they are produced in Bunches; and where they are produced ſingly, they are double: But this ſo rare, that many times upon a large Shrub there cannot be found ſix double Flowers.

The variegated Sort is preſerved in the Gardens of ſuch as are curious in ſtrip'd Plants, tho' there is no great Beauty in it, becauſe when the Plants are vigorous, the Stripes in the Leaves do ſcarcely appear.

The Dwarf Sort is not worth a Place in a Garden, unleſs for the Sake of Variety, ſince it never produces any Flowers.

All theſe Plants may be eaſily propagated, by taking off their Suckers in *Autumn*, (which they produce very plentifully) and planting them out in a Nurſery at three Feet Diſtance Row from Row, and a Foot aſunder in the Rows, obſerving to keep the Ground between them conſtantly clear from Weeds, as alſo to dig it up every *Spring* to looſen it, that the Roots of the Plants may more readily extend themſelves. In this Nurſery they may remain two Years, by which Time they will be fit to tranſplant out where they are to remain; which may be into ſmall Wilderneſs Quarters, or amongſt flowering Shrubs in Clumps, obſerving to place them with other Sorts of Shrubs of the ſame Growth, for theſe ſeldom do grow above ſix or ſeven Feet high in *England*, and the Dwarf Sort not more than three or four.

They are extreme hardy, ſo may be planted in almoſt any Soil or Situation, and will require no farther Culture but to take off the Suckers every Year, and cut out the dead Wood, as alſo to keep them clear from Weeds in *Summer*, and dig the Ground about their Roots every *Winter*, which will make them thrive and flower very plentifully. The Seaſon of their flowering is in *May*, and in cool Seaſons they do continue in Beauty the firſt Part of *June*: Their Flowers have a Scent ſomewhat like thoſe of the *Orange-tree*, from whence it had the Name of *Mock-orange*: But if theſe are placed in a cloſe Room, or are ſmelt to too cloſely, they have a ſtrong, diſagreeable Scent, and too powerful for the Ladies; but when they are in the open Air, the Scent is not ſo affecting.

T A

TABERNÆMONTANA.

The *Characters* are;

It hath a tubulous Flower, conſiſting of one Leaf, which is ſpread open toward the Top, and divided into ſeveral Parts; from the Bottom of the Flower ariſes the Pointal, which afterwards becomes the Fruit, compoſed of two Capſules which open lengthways, and are filled with oblong Seeds, ſurrounded with a thin Pulp.

The *Species* are;

1. **Tabernæmontana** *lacteſcens, citrii foliis undulatis. Plum. Nov. Gen.* Milky Tabernæmontana, with a waved Citron Leaf.
2. **Tabernæmontana** *lacteſcens, Lauri folio, flore albo, ſiliquis rotundioribus. Houſt.* Milky Tabernæmontana, with a Bay Leaf, and a white Flower, and rounder Pods.

The firſt of theſe Sorts is common in the Iſland of *Jamaica*, and in ſeveral other Places in the warm Parts of *America*; where it riſes to the Height of fifteen or ſixteen Feet, having a ſmooth ſtrait Trunk, covered with a whitiſh Bark; at the Top of the Trunk come out the Branches, which are irregular, and beſet with ſhining green Leaves; from the Foot-ſtalks of theſe Leaves are produced the Flowers, which are yellow, and extremely ſweet-ſcented: Theſe Flowers are ſucceeded by two forked Pods, in which the Seeds are contained. This Genus of Plants is very near of kin to the *Nerium* or *Oleander*, and has been by ſome Botanical Writers ranged under that Head; but the Seeds of this Genus have no Down adhering to them, as have thoſe of the *Oleander*: and being included in a ſoft pulpy Subſtance, Father *Plumier* has conſtituted this Genus in Honour to Dr. *James Theodore*, who was called *Tabernæmontanus*, from a little Village in *Germany*, where he was born. He was one of the moſt knowing Botaniſts of his Age, and publiſhed at *Francfort* a Folio, in a long Form, in the Year 1590, in which are the Figures of two thouſand two hundred and fifty Plants.

The ſecond Sort was diſcovered at *La Vera Cruz*, by the late Dr. *William Houſtoun*, who ſent the Seeds into *England*, from whence ſeveral of the Plants have been raiſed.

Both theſe Plants are very impatient of Cold, ſo will not live in this Country, unleſs they are placed in a warm Stove: they may be propagated by Seeds, which ſhould be ſown early in the *Spring*, on a Hot-bed; and when the Plants are come up, they muſt be carefully tranſplanted into ſmall Pots, filled with light, rich Earth, and then plunged into a Hot-bed of Tanners-bark, being careful to ſhade them in the Heat of the Day, until they have taken new Root; after which Time they muſt have free Air admitted to them every Day when the Weather is warm, but if the Nights ſhould prove cold, the Glaſſes of the Hot-bed ſhould be covered with Mats every Evening, ſoon after the Sun goes off from the Bed. Theſe Plants muſt be often refreſhed with Water, but it muſt not be given to them in large Quantities, eſpecially while they are young; for as they are full of a milky Juice, ſo they are very ſubject to rot with much Moiſture.

The Plants may remain during the *Summer* Seaſon in the Hot-bed, provided the Tan is ſtirred up to renew the Heat when it wants, and a little new Tan added; but at *Michaelmas*, when the Nights begin to be cold, the Plants ſhould be removed and plunged into the Bark-bed in the Stove, where, during the *Winter* Seaſon, they muſt be kept in a moderate Degree of Warmth; and in cold Weather they ſhould have but a little Water given to them, leſt it ſhould rot them. As theſe Plants are too tender to live in the open Air in this Country, ſo they ſhould conſtantly remain in the Stove, where, in warm Weather, they may have free Air admitted to them, by opening the Glaſſes of the Stove, but in cold Weather they muſt be kept warm; with this Management the Plants will thrive and produce their Flowers, and as they are always green, ſo they will make a pleaſant Diverſity amongſt other tender exotick Plants in the Stove.

Theſe Plants may alſo be propagated by Cuttings, during the *Summer* Seaſon; which ſhould be cut off from the old Plants, and laid to dry in the Stove five or ſix Days before they are planted, that the wounded Parts may heal, otherwiſe they will rot. Theſe Cuttings ſhould be planted in Pots filled with freſh light Earth, and plunged into the Hot-bed of Tanners-bark, obſerving to ſhade them from the Sun in the Middle of the Day in hot Weather, as alſo to refreſh them now and then with a little Water. When the Cuttings have taken Root, they may be tranſplanted into ſeparate Pots, and treated in the ſame Manner as thoſe which are raiſed from Seeds.

TAGETES; African *or* French Marygold.

The *Characters* are;

The Flower is radiated, conſiſting of divers Florets, which are plain, and cut into ſeveral Segments; but the Diſk of the Flower conſiſts of half Florets, which ſtand upon the Embryo's; the Flower-cup conſiſts of one Leaf, is tubulous, and incloſes the Embryo's which afterwards become angular Seeds, with a a Leaf upon the Head of each.

The *Species* are;

1. TAGETES *maximus rectus, flore ſimplici ex luteo pallido. J. B.* Greateſt upright African Marygold, with a ſingle, pale, yellow Flower.

2. TAGETES *maximus rectus, flore maximo multiplicato. J. B.* Greateſt upright African Marygold, with a large double Flower.

3. TAGETES *maximus rectus, flore maximo multiplicato aurantii coloris.* Greateſt upright African Marygold, with a very large double Orange-colour'd Flower.

4. TAGETES *maximus rectus, flore maximo multiplicato ſulphurei coloris.* Greateſt upright African Marygold, with a very large double Brimſtone-colour'd Flower.

5. TAGETES *maximus rectus, flore maximo multiplicato, pallide luteo odorato.* Greateſt upright African Marygold, with a very large double Flower, of a pale, yellow Colour, and a ſweet Scent.

6. TAGETES *maximus rectus, flore maximo multiplicato, pallide luteo & fiſtuloſo.* Greateſt upright African Marygold, with a large, double, pale, yellow, and piped Flower, *commonly call'd* The Quilled African.

7. TAGETES *Indicus medius, flore ſimplici luteo pallido. J. B.* Indian middle French Marygold, with a ſingle, pale, yellow Flower.

8. TAGETES *Indicus medius, flore luteo multiplicato. H. L.* The Middle French Marygold, with a double yellow Flower.

9. TAGETES *Indicus minor, ſimplici flore, ſive Caryophillus Indicus, ſive flos Africanus. J. B.* Leſſer *or* Common French Marygold, with a ſingle Flower, *call'd* Indian Clove Gilliflower.

10. TAGETES *Indicus minor, multiplicato flore. J. B.* Double French Marygold, *vulgo.*

11. TAGETES *Indicus, flore ſimplici fiſtuloſo. H. L.* Single French Marygold, with a piped Flower.

12. TAGETES *Indicus, flore fiſtuloſo duplicato. H. L.* Double French Marygold, with a piped Flower.

13. TAGETES *Indicus minimus, flore ſericea hirſutie obſito. H. L.* The leaſt French Marygold, with a ſoft hairy Flower.

All theſe Plants are annual, ſo muſt be propagated from Seeds every *Spring*, which may be ſown upon a moderate Hot-bed in *March*; and when the Plants are come up, they ſhould have Plenty of freſh Air, for if they are drawn too much, they will not afterward become handſome, notwithſtanding they have all poſſible Care taken of them. When they are about three Inches high, they ſhould be tranſplanted on a freſh Hot-bed, which may be arched over with Hoops, and covered with Mats, (for theſe Plants are hardy enough to be brought up without Glaſſes:) In this Bed they ſhould be planted about ſix Inches aſunder each Way, obſerving to water and ſhade them until they have taken Root; but as the Plants do acquire Strength, ſo they ſhould be inur'd to bear the open Air by Degrees; and about the Beginning of *May*, they ſhould be taken up, with a Ball of Earth to the Root of each Plant, and plac'd in a Nurſery in a warm Situation, about eighteen Inches aſunder, obſerving to water and ſhade them until they have taken Root, and in very dry Weather the Waterings ſhould be repeated: In this Nurſery they may remain until their Flowers appear, ſo as to diſtinguiſh thoſe with double Flowers: which may be taken up with a Ball of Earth to each Plant, and planted into the Borders of the Parterre Garden, or into Pots, for furniſhing the Courts, *&c.* where the ſeveral Varieties being intermix'd with other annual Plants, do afford an agreeable Variety.

Thoſe with ſingle Flowers ſhould be pull'd up, and thrown away as good for little, becauſe the Seeds produc'd from them will rarely produce double Flowers; therefore great Care ſhould be taken to ſave only the Seeds of thoſe whoſe Flowers are very double of every kind, from which there will always be a good Quantity of double ones produc'd, tho' from the very beſt Seeds there will always be many ſingle Flowers; but the ſmall Sorts do always produce a greater Number of double Flowers than the large, which are more apt to degenerate.

Theſe Plants have a ſtrong, diſagreeable Scent, eſpecially when handled; for which Reaſon they are not ſo greatly eſteem'd for planting near Habitations: but the Flowers of the ſweet-ſcented Sort being more agreeable, are moſtly coveted to plant in ſmall Gardens. All theſe Sorts do begin to flower in *May*, and continue all the latter Part of the Year, until the Froſt prevents their Flowering: for which, together with the little Trouble requir'd in their Culture, they have greatly obtain'd in moſt *Engliſh* Gardens.

TAMARINDUS; [ſo call'd of *Tamur*, a *Date*, becauſe its Fruit does ſomewhat reſemble a *Date*] The Tamarind-Tree.

The *Characters* are;

The Flower conſiſts of ſeveral Leaves, which are ſo plac'd as to reſemble a papilionaceous one in ſome meaſure; but theſe expand circularly: From whoſe many-leav'd Flower-cup riſes the Pointal, which afterwards becomes a flat Pod, containing many flat angular Seeds, ſurrounded with an acid, blackiſh Pulp.

We have but one *Species* of this Tree; *viz.*

TAMARINDUS. *Raii Hiſt.* The *Tamarind*-Tree.

There are ſome who imagine the *Tamarind*-Tree of the *Eaſt-Indies*, and that of the *Weſt-Indies* to be different, but I don't remember to have ſeen them diſtinguiſh'd by any Botanick Author; though, indeed, from the different Appearance of the Pods, they ſeem very different; for the Pods which I have ſeen of the *Eaſt-Indian* Sort were very long, and contain'd ſix or ſeven Seeds in each; whereas thoſe of the *Weſt-Indies* do rarely contain more than three or four: but from the Plants which I have rais'd from both Sorts of Seeds, I can't diſtinguiſh them aſunder as yet.

Theſe Trees do grow to a great Magnitude in their native Countries; but in *Europe* they are preſerv'd as Curioſities by thoſe who are Lovers of rare Plants.

They are eaſily propagated by ſowing their Seeds on a Hot-bed in the *Spring*; and when the Plants are come up, they ſhould be planted each into a ſeparate ſmall Pot fill'd with light rich Earth, and plung'd into a Hot-bed of Tanners-Bark, ners-Bark, to bring 'em forward, obſerving to water and ſhade them until they have taken Root; and as the Earth in the Pots appears dry, ſo they muſt be water'd from time to time, and ſhould have Air given to them in Proportion to the Warmth of the Seaſon, and the Bed in which they are plac'd: When the Pots in which they are planted are fill'd with their Roots, the Plants ſhould be ſhifted into Pots of a larger Size, which muſt be fill'd up with rich light Earth, and again plung'd into the Hot-bed, giving them Air, as before, according to the Warmth of the Seaſon: But in very hot Weather the Glaſſes ſhould be ſhaded with Mats in the Heat of the Day, otherwiſe the Sun will be too violent for them through the Glaſſes: Nor will the Plants thrive if they are expos'd to the open Air, even in the warmeſt Seaſon, ſo that they muſt be conſtantly kept in the Bark-ſtove both *Winter* and *Summer*, treating them, as hath been directed, for the *Ananas*, with whoſe Culture they will thrive exceedingly.

Theſe Plants, if rightly manag'd, will grow very faſt, for I have had 'em upwards of three Feet high in one *Summer* from Seed, and had one Plant which produc'd Flowers the ſame Seaſon it was ſown; but this was accidental, for I have never ſince had any of them flower, altho' I have ſeveral Plants of different Ages, one of which is five Years old, and about ſeven Feet high, with a large ſpreading Head.

TAMARISCUS, The Tamariſk-Tree.

The *Characters* are;

The Flowers are roſaceous, conſiſting of ſeveral Leaves, which are placed orbicularly; from whoſe Flower-cup riſes the Pointal, which afterwards becomes a Pod, (ſomewhat like thoſe of the Sallow) *which opens into two Parts, and contains ſeveral downy Seeds.*

The *Species* are;

1. Tamariscus *Narbonenſis. Lob. Icon.* The French *or* narrow-leav'd Tamariſk-Tree.
2. Tamariscus *Germanica. Lob. Icon.* The German Tamariſk.

Theſe Trees are preſerv'd in the Gardens of thoſe who are curious in collecting the various Kinds of Trees and Shrubs; but they have not much Beauty to recommend them; for their Branches are produced in ſo ſtraggling a manner, as not by any Art to be train'd up regularly, and their Leaves are commonly thin upon the Branches, and do fall away in *Winter*; ſo that there is nothing to recommend them but their Oddneſs.

They may be eaſily propagated, by laying down their tender Shoots in the *Spring*, or by planting Cuttings in an Eaſt Border at that Seaſon, which, if ſupplied with Water in dry Weather, will take Root in a ſhort time; but they ſhould not be removed until the following *Spring*; at which Time they may be either placed in a Nurſery, to be train'd up two or three Years, or elſe into the Quarters where they are deſign'd to remain, obſerving to mulch their Root, and water them according as the Seaſon may require, until they have taken Root; after which, the only Culture they will require, is, to prune off the ſtraggling Shoots, and keep the Ground clean about them.

Theſe Plants delight in a ſandy Soil, not over-rich, and ſhould be placed amongſt Shrubs of a middling Growth; for they rarely grow above 15 or 16 Feet high in *England*, but are very hardy in reſpect to Cold.

TAMNUS, The Black Briony.

The *Characters* are;

It is Male and Female in different Plants; the Flowers of the Male Plant conſiſt of one Leaf, and are Bell-ſhaped, but theſe are barren; the Embryo's are produced on the Female Plants, which afterwards become an oval Berry, including roundiſh Seeds: to theſe Notes ſhould be added, that theſe Plants have no Claſpers, as the White Briony hath.

The *Species* are;

1. Tamnus *racemoſa, flore minore luteo palleſcente. Tourn.* The common Black Briony.
2. Tamnus *Cretica, trifido folio. Tourn. Cor.* Black-briony of Crete, with a trifid Leaf.
3. Tamnus *Americana, tubifera, radice fungi-formi. Plum.* American Black-briony, with a Root reſembling a Muſhroom.
4. Tamnus *Americana, racemoſa, minor. Plum.* Smaller branching American Black-briony.
5. Tamnus *Americana, racemoſa, major. Plum.* Greater branching American Black-briony.
6. Tamnus *Americana, amplis foliis, ſubtus purpureis. Plum.* American Black-briony, with large Leaves, which are purple on their Underſide.
7. Tamnus *Americana, anguriæ folio. Plum.* American Black-briony, with a Water-melon leaf.

The firſt Sort is rarely cultivated in Gardens, but grows wild under the Sides of Hedges in divers Parts of *England*, and is there gather'd for Medicinal Uſe. It may be eaſily propagated by ſowing the Seeds ſoon after they are ripe, under the Shelter of Buſhes, where, in the *Spring*, the Plants will come up, and ſpread their Branches over the Buſhes, and ſupport themſelves, requiring no farther Care; and their Roots will abide many Years in the Ground, without decaying.

The ſecond Sort was diſcovered by Dr. *Tournefort* in the *Levant*, from whence he ſent the Seeds to the Royal Garden at *Paris*. This is a very hardy Plant, ſo will thrive in the open Air in this Country. It may be propagated by Seeds, which ſhould be ſown in the *Autumn* (ſoon after they are ripe) on a Bed of freſh Earth, and when the Plants are come up, they muſt be kept clear from Weeds, and thinned where they are too cloſe together, which is all the Management they will require, till the *Autumn* following, when the Roots ſhould be taken up as ſoon as the Leaves decay, and tranſplanted where they are deſigned to remain, which ſhould be near a Hedge, on which they may climb, otherwiſe the Branches will trail on the Ground, and in wet Seaſons will rot.

The other five Sorts were diſcovered by Father *Plumier* in *America*; theſe are very common in *Jamaica*, and ſeveral other Places in the *Weſt-Indies*, where the Woods have not been cleared; but theſe are too tender to live in the open Air in *England*, ſo muſt be preſerved in Stoves, and kept in a moderate Temperature of Warmth in the *Winter* Seaſon. They are propagated by Seeds, which ſhould be ſown on a moderate Hot-bed early in the *Spring*; and when the Plants are come up, they ſhould be each planted into a ſeparate ſmall Pot, filled with freſh, light Earth, and plunged into a Hot-bed of Tanners-bark, where they ſhould remain during the *Summer* Seaſon, obſerving to water them plentifully in hot Weather, as alſo to admit a large Share of Air to them, by raiſing the Glaſſes of the Hot-bed with Stones every Day. In the *Autumn* the Branches of theſe Plants will decay to the Root, at which Time the Pots ſhould be removed and placed in the Stove, where, during the *Winter* Seaſon, the Roots will remain in an unactive State, ſo ſhould not have too much Moiſture leſt it rot them; in the *Spring* they will ſhoot out again, when the Pots ſhould be placed near ſome Support to which their Shoots may faſten, otherwiſe they will twine round whatever Plants do grow near them; for in the Countries of their natural Growth, they climb up the talleſt Trees to a very great Height. Theſe are Male and Female in different Plants, as is the common Sort.

TANACETUM, Tanſy.

The *Characters* are;

It hath a floſculous Flower, conſiſting of many Florets, divided into ſeveral Segments, ſitting on the Embryo, and contained in a ſquamous and hemiſpherical Empalement; the Embryo afterwards becomes a Seed, not at all downy: To theſe Notes muſt be added, thick Flowers gathered into a Kind of Head.

The *Species* are;

1. Tanacetum *vulgare luteum. C. B. P.* Common Tanſy.
2. Tanacetum *foliis criſpis. C. B. P.* Curled *or* Double Tanſy.
3. Tanacetum *vulgare, foliis variegatis.* Common Tanſy, with ſtriped Leaves.
4. Tanacetum *vulgare luteum maximum. Boerh. Ind.* The largeſt common Tanſy.
5. Tanacetum *Africanum arboreſcens, foliis lavendulæ, multifido folio. H. Am.* African ſhrubby Tanſy, with Leaves like the multifid Lavender.
6. Tanacetum *Orientale, minus. Tourn. Cor.* Smaller Eaſtern Tanſey.
7. Tanacetum *Davuricum, humilius, foliis tenuiter diſſectis. Amman.* Tanſy of Davuria, with fine cut Leaves.
8. Tanacetum *Africanum, fruticans, multiflorum, foliis tanaceti vulgaris decuplo minoribus. Boerh. Ind.* Shrubby African Tanſey, with many Flowers, and Leaves like the common Sort, but ten times leſs.

The firſt and ſecond Sorts are very common in *England*, being promiſcuouſly cultivated in Gardens, for the Uſe of the Kitchen; but the firſt ſhould be propagated for medicinal Uſe. The third Sort is a Variety of the firſt, which is by ſome preſerved for the ſake of its variegated Leaves. The fourth Sort is very like the common in Appearance, but is much larger, and has leſs Scent.

All theſe Sorts are eaſily propagated by their creeping Roots, which, if permitted to remain undiſturbed, will in a ſhort Time overſpread the Ground where they are planted; ſo that the Slips ſhould be placed at leaſt a Foot aſunder, and in particular Beds, where the Paths round them may be often dug, to keep their Roots within Bounds. They may be tranſplanted either in *Spring* or *Autumn*, and will thrive in almoſt any Soil or Situation.

The common *Tanſy* is greatly uſed in the Kitchen early in the *Spring*, at which Seaſon that which is in the open Ground, or eſpecially in a cold Situation, is hardly forward enough to cut; ſo that where this is much wanted at that Seaſon, it is the beſt Way to make a gentle Hot-bed in *December*, and plant the old Roots thereon, without parting them, and arch the Bed over with Hoops, to cover it with Mats in cold Weather, by which Method the *Tanſy* will come up in *January*, and be fit to cut in a ſhort Time after.

The fifth Sort was brought from the *Cape of Good Hope*, and is preſerved in the Gardens of thoſe who are curious in collecting exotick Plants. This may be propagated by planting Cuttings or Slips during any of the *Summer* Months, upon a Bed of light, rich Earth, obſerving to water and ſhade them, until they have taken Root, after which they may be taken up, and planted in Pots filled with light, freſh Earth, placing them in a ſhady Situation until they have taken new Root, and then they may be expoſed in an open Place, amongſt other exotick Plants, until the Beginning of *October*, when they muſt be removed into the Greenhouſe, obſerving to place them in the cooleſt Part thereof, and as near the Windows as poſſible, that they may enjoy the free Air in mild Weather, otherwiſe they will draw up weak, and be liable to grow mouldy, and decay.

They muſt alſo be frequently watered; but in very cold Weather they muſt not have too much Water given them at each Time; tho' in *Summer* they ſhould have it in Plenty. With this Management (together with obſerving to ſhift them into larger Pots, as they ſhall require it) the Plants will grow large, and produce a great Quantity of Flowers, which commonly appear early in the *Spring*, and thereby greatly add to the Variety of the Green-houſe.

The ſixth Sort was diſcovered by Dr. *Tournefort* in the *Levant*, from whence he ſent the Seeds to the Royal Garden at *Paris*. The ſeventh Sort was ſent to me from *Peterſburgh*, by Dr. *Amman*, who is Profeſſor of Botany in that Univerſity. Theſe are both very hardy Plants, ſo may be propagated by Seeds, or parting of their Roots, in the ſame Manner as is practiſed for the common Sort, but the Roots of theſe Kinds do not creep ſo much as thoſe of the common Sort.

The eighth Sort was brought from the *Cape of Good Hope* to ſome curious Gardens in *Holland*, where it has been propagated and been diſperſed to ſeveral Parts of *Europe*. This Kind will riſe to the Height of three or four Feet, and become ſhrubby, producing a great Number of Flowers at the Extremity of every Branch, early in the *Spring*, but ſeldom perfects its Seeds in this Country. It may be propagated with great Eaſe, for every Cutting which is planted in *Summer* will take Root, provided they are ſhaded from the Sun, and duly watered in dry Weather: When theſe Cuttings are rooted, they ſhould be tranſplanted into Pots filled with freſh Earth, and placed in a ſhady Situation, until they have taken new Root, after which Time they may be placed amongſt other hardy exotick Plants, in a ſheltered Situation, where they may remain until *October*, when they muſt be removed into the Green-houſe, and placed where they may enjoy as large a Share of free Air as poſſible in mild Weather, otherwiſe the Shoots will draw weak and be unſightly. In *February* theſe Plants will begin to flower, and they will continuing flowering ſeveral Months, ſo do afford an agreeable Variety amongſt other Plants in the Green-houſe; and being hardy, in reſpect to Cold, and eaſy to propagate, renders them worthy of a Place in every good Collection of Plants.

TAN or TANNERS-BARK, is the *Bark* of the Oak Tree, chopped and ground into coarſe Powder, to be uſed in Tanning or Dreſſing of Skins; after which it is of great Uſe in Gardening: Firſt, by its Fermentation, (when laid in a Body) which is always moderate, and of a long Duration, which renders it of great ſervice to Hot-beds: and, ſecondly, after it is well rotted, it becomes excellent Manure for all Sorts of cold, ſtiff Land, upon which one Load of *Tan* is better than two of the beſt rotten Dung, and will continue longer in the Ground.

The Uſe of *Tan* for Hot-beds has not been very many Years known in *England*, and was brought over firſt from *Holland*, where it had been long uſed for thoſe Purpoſes: I have been informed, that it was firſt uſed in *England* for raiſing Orange Trees, which is about the Beginning of King *William*'s Reign; but it was diſuſed long after that, and it is within fifteen or ſixteen Years paſt that it was again brought into Uſe, for raiſing the Pine-apple; ſince which Time it has yearly grown more in Uſe for Hot-beds; and I doubt not but in a few Years it will be generally uſed for thoſe Purpoſes wherever it can be procured eaſily.

There are commonly two or three Sorts of *Tan*, which are ground into Powder of different Sizes, ſome being in very groſs Pieces, and others are ground very fine; theſe are different in their Effects, when laid to ferment; for the ſmall Sort will heat more violently, but will loſe its Heat in a ſhort Time; but the large Sort being moderate in Fermentation, does continue its Heat a long Time: So that whoever makes a Hot-bed of *Tan*, muſt proportion a Mixture of each Sort according as they would have their Beds work; for if they intend to have a moderate Heat, and can ſtay a Fortnight or three Weeks, for its beginning to ferment, they ſhould uſe but very little ſmall *Bark*: But where the Heat is wanted ſooner, there ſhould be a larger Proportion of the ſmall *Bark*.

This *Tan* ſhould be taken in a Fortnight's Time after it comes out of the Pit, and laid up in a round Heap for a Week, to drain; (eſpecially if it be in *Winter* or *Spring*, while the Seaſon is moiſt) after which it may be put into the Trench where the Hot-bed is deſigned, which ſhould be bricked on the Sides quite round, to prevent the Earth from mixing with the *Bark*. Theſe Trenches ſhould be proportioned to the Size of the Frames which are to cover them, and the Depth in the Ground, according to the Moiſture of the Place where they are ſituated; for if the Ground is very wet, the Bed ſhould be raiſed above the Surface of the Ground, becauſe if ever the Water riſes into the *Bark*, it will cool it ſo much as not to be retrieved again to its former Heat, without taking it out of the Trench again, and freſh mixing it up.

The Thickneſs which the Bark ſhould be laid in the Trench, muſt not be leſs than three Feet, and the Width four Feet; for where it is laid in a leſs body, it ſeldom heats, and if it is forced by laying hot Dung under it (as is ſometimes practiſed, the Heat will ſoon decay. In laying the *Bark* into the Trench, you ſhould be very careful to ſtir up every Part of it, that it may not ſettle in Lumps, as alſo to preſs it down gently; but by no Means tread or beat it down too cloſe, which will prevent its heating. Then the Glaſſes ſhould be placed over the Bed immediately after it is finiſhed, which ſhould be kept cloſe down, in order to draw a Heat in the *Bark*, and to prevent Wet from falling thereon; in a Fortnight's Time after the *Bark* will begin to heat, and when it is found of a due Temper, the Plant may be removed into it.

A Hot-bed well prepared with this *Tan*, will continue a moderate Heat upwards of ſix Months, and there being very little Steam ariſing from it, in compariſon to Horſe-dung, renders it much better for the Growth of all Sorts of Plants; and when the Heat begins to decay, if the *Tan* be freſh ſtirred up, and a little new added to it, it will heat again, and continue ſome Months longer. The farther particular Directions for the Management of theſe Hot-beds, being already exhibited under the Article of *Hot-beds*, the Reader is deſired to turn back to that for farther Inſtructions.

In the above Account I have mentioned only two or three Sorts of *Bark*; but upon being more acquainted with it, I find there are ſeveral Degrees of Fineneſs to which the Tanners do grind their *Bark*; and in ſome Countries they only chop their *Bark* into large Pieces before they uſe it, ſo that the latter Sort is not proper for Hot-beds, for the Pieces being very large, do lie ſo hollow, as to admit the Air amongſt it, and unleſs there is a good Quantity of ſmall *Bark* mixed with it, it ſeldom ferments well, therefore where the ground *Bark* can be procured, it ſhould always be preferr'd to that which is chopp'd. But where no other Sort can be procured, there ſhould be a Quantity of Bran, Saw-duſt or Chaff mixed with the *Tan*, which when well mixed, will cauſe it to ferment, and whenever the Heat abates, if the *Tan* is ſtirred up from the Bottom of the Bed, and ſome freſh Bran or Saw-duſt added, it will renew the Heat of the *Bark*; for as the Pieces are large, ſo it will be much longer before it is conſumed than the ſmall *Bark*, for ſo long as any Subſtance remains in it, there will be a Heat continued, which may be increaſed by freſh ſtirring of it, and adding a little new *Bark*, Bran or Saw-duſt.

The beſt Sort of *Tan* for Hot-beds, is that which is ground of a middling Size, neither too ſmall nor too large; this will ferment moderately, and continue its Heat a long Time. Before the *Tan* is put into the Pit where the Hot-bed is deſigned, it will be proper to lay it in a round Heap, until it begins to ferment, eſpecially if it is in the *Spring* or *Autumn*; but in the *Summer* Seaſon there is no need of this Precaution, becauſe at that Seaſon, the Sun thro' the Glaſſes of the Hot-bed, will ſoon cauſe it to ferment; and where there is ſome warm *Tan* left in the Pit, to mix with the new, that will alſo cauſe it to heat ſoon, provided the new *Tan* is not too wet.

The Thickneſs which I directed the *Bark* to be laid in the Hot-bed, was three Feet, and the Width at leaſt four Feet, but it will be much better to have the Bed ſix or ſeven Feet wide, or more, where there is proper Conveniency for it; becauſe when the Bed is narrow, the two outſide Rows of Pots will receive little Benefit from the Heat; and where the Width is ſo great, two Feet and a half in Thickneſs will be ſufficient. For the ſame Reaſon alſo the Length of the Bed ſhould be in Proportion; therefore I ſhould always prefer a Bed of twenty Feet long, to thoſe which are ſhorter. There are ſome Perſons who make their Tan-beds much wider than what is here mentioned; but I think they ſhould not be more than eight Feet wide, becauſe it will be very difficult to come at thoſe Plants which are plunged in the Middle of the Bed, without injuring thoſe near the Sides, but this is only for Bark-pits in Stoves; for where the Hot-bed is made in Frames, it ſhould not exceed ſix Feet and a half, which is full as wide as can be well reached, to water and weed the Pots which are plunged therein.

There are ſome Perſons who imagine their Beds ſhould always be very warm, ſo are frequently ſtirring them, and adding new *Tan* to them, and very often lay warm Horſe-dung under the *Tan*, or round the Sides of it to increaſe the Heat; which is not neceſſary, becauſe, unleſs it be to raiſe very difficult exotick Seeds, or to forward the rooting of Plants in *Spring* or *Autumn*, there doth not require an extraordinary Heat to the Roots of Plants, which many times is very prejudicial to them; for, from ſome Experiments which were made by a Friend of mine at *Jamaica*, by placing Thermometers in the Earth at different Depths, he found the Heat nearly equal through the Year (excepting juſt at the rainy Seaſons) at three Feet below the Surface; and this Heat was not greater than that of *Tan* when in a very ſlow Fermentation. So that when the *Tan* is too hot, it is not ſo proper for the Growth of Plants, as when the Warmth is moderate, which is a Proof of the Abſurdity which ſome People are guilty of, in ſuppoſing they can produce as good Fruit of the *Ananas* with *Bark* alone, as thoſe who have Stoves to warm the Air of the Stove, in which the Plants are placed; for although there is no Neceſſity of a very great Heat to their Roots, yet the circumambient Air ſhould be ſufficiently warmed in *Winter*, otherwiſe the Plants will make no Progreſs; ſo that inſtead of ſhewing their Fruit in *January* and *February*, which is their proper Seaſon, they do often fruit in *May* and *June*, and ſometimes later, and conſequently do not ripen till the following *Winter*, when the Sun having little Power of heating the Air, the Fruit are good for little. It is very common to ſee the Plants, which are placed in Stoves, dropping their Leaves in *Winter*, and puſhing out new ones ſoon after, which ſeldom remain long on the Plants before they fall; this is frequently occaſioned by the Bed being very warm in which they are placed, when at the ſame Time the Air of the Stove is never ſufficiently warmed, which is certainly a great Error; for by the Experiments which my Friend made with ſeveral Thermometers in *Jamaica*, he found that even in the cooleſt Seaſons, the Spirit ſeldom fell ſo low as forty Degrees above the freezing Point, in the Night, and in the Day-time at the ſame Seaſons, the Spirit uſually roſe to ſixty Degrees above the freezing Point. But in the hotter Seaſons, the Spirit roſe ſo high, as to break the Glaſſes of the common Thermometers when placed entirely in the Shade.

The Hot-beds in the Stoves which are made of good *Tan*, will rarely want renewing oftener than twice a Year, that is in the Beginning of *March*, and toward the End of *September*; but at neither of theſe Times ſhould the *Bark* be entirely taken out of the Pits; for if that which is moſt conſumed is thrown out (which is generally the upper Part) and the reſt mixed with the new *Tan*, it will ferment again ſlowly, and prevent the Bed from being too hot, which is frequently the Caſe when the Bed is entirely made of new *Tan*. But this only to be underſtood of ſuch Hot-beds which are deſigned to maintain tender exotick Plants; for where they are made for raiſing of *Cucumbers* and *Melons*, the Beds ſhould be entirely made of new *Tan* (excepting juſt about the Holes where the Plants are placed, which ſhould have ſome old *Tan*, for the Plants to root in, after their Roots have extended thro' the Earth laid in the Holes) which ſhould be laid in a Heap to ferment, at leaſt a Fortnight or three Weeks, before the Bed is made, and then it will be proper to wait a Week, that the Bed may be in a proper Temperature of Heat, before the Plants are placed into it. Thoſe Perſons who have *Tan* in plenty, and are willing to uſe it for Hot-beds, to raiſe *Cucumbers* and *Melons*, ſhould have their Plants in Baskets, ſo that they may at any Time remove them into the Hot-bed, without injuring them: And if after they are placed in the Hot-bed, the Heat ſhould be too violent, they may be raiſed up for a few Days until the Heat is abated, which will prevent the Heat from ſcorching the Roots of the Plants. The Hot-beds which are made of *Tan*, if they are properly managed, are much preferable to thoſe made of Horſe-dung, for theſe Purpoſes; for as the Heat will not be ſo violent as is that of the Horſe-dung, ſo the Plants will not be in ſo much Danger of being ſcorched; and the Heat continuing longer in theſe Hot-beds, the Fruit will be brought forward much ſooner; and the Plants will extend their Roots quite thro' the *Tan*, which will occaſion their growing ſtronger, ſo that the Fruit will be large and well nouriſhed.

When the *Tan* which is conſumed in the Hot-beds is thrown out, it is a very proper Manure for ſtiff, cold Land, but if it is laid on hot, dry Ground, it ſhould be ſpread very thin, otherwiſe inſtead of mending the Land, it will increaſe its Heat, and render it too light. There are ſome Perſons who prepare their Flower-beds with rotten Tan, which from many Experiments I have found has proved very pernicious to them, eſpecially to *Ranunculus's* and *Anemonies*; for in Beds thus prepared, I have loſt more than half the Roots, and thoſe which have lived, produced very weak Flowers; and upon taking up their Roots the following *Summer*, I have found them ſmaller than when they were planted: Whereas in ſome adjoining Beds, which were prepared with rotten Neats-dung, the Roots have very few of them died, and have flowered very ſtrong, and made a large Increaſe; though they were planted at the ſame Seaſon, in the ſame Situation, and had equal Managemet. I have alſo found that rotten Tan is very prejudicial to Orange Trees, therefore it ſhould never be mixed with the Earth, which is deſigned for them, nor for any other Plants which require a cool loamy Soil; for nothing is more prejudicial to them than this Manure.

But altho' this rotten Tan is improper for Flowers, Orange Trees, and many other Plants in Gardens, yet it is an excellent Manure for ſtrong cold Corn-land; and I have often been ſurpriſed to ſee in ſome Countries great Heaps of Tan lie neglected in Tanners-yards, when the neighbouring Farmers have fetched much worſe Manure ten or fifteen Miles for their Land; whereas if they were once to try this, they would prefer it to moſt other Manures yet known.

TAPIA, The Garlick Pear-Tree.

The *Characters* are;

It hath an Anomalous Flower, conſiſting of four Petals or Leaves, which ſtand erect; the lower Part being occupied by a Number of Chives; the Pointal, which is fixed on a long Footſtalk, riſes from the Center of the Empalement, and afterwards becomes a globular fleſhy Fruit, in the Center of which are included many Seeds, which are ſhap'd almoſt like Kidney's.

We have but one *Species* of this Plant, *viz.*

TAPIA *arborea triphylla. Plum. Nov. Gen.* The Garlick Pear-Tree, vulgo.

The Name *Tapia* is what the *Armenians* call this Tree; ſo Father *Plumier* has conſtituted it as a new Genus by the ſame Name. The *Engliſh* Inhabitants of *America* call it Garlick-Pear, from the Fruit having a very ſtrong Scent of Garlick.

This Tree is pretty common in *Jamaica*, and ſeveral other Places in the warmer Parts of *America*, where it uſually riſes to the Height of thirty or forty Feet, and ſpreads into many Branches. During the dry Seaſons, theſe Trees are uſually deſtitute of Leaves, but when the Rains begin, they thruſt out their Flowers at the Extremity of their

Branches, and ſoon after the Leaves come out, which are of a dark green Colour, and are always three together on the ſame Footſtalk. When the Flowers fall off, the Pointal becomes a round Fruit, about the Size of a Tennis-ball; which when ripe, has a rough browniſh Rind, and a mealy ſweetiſh Pulp, ſomewhat like ſome of the *European* Pears, but has a ſtrong Scent of Garlick. This Fruit is often eaten by the Inhabitants of *America*, by way of Deſert, tho' they are not very tempting. The Swine, which are ſometimes fattened with this Fruit, have the ſtrong Scent of Garlick communicated to their Fleſh. Theſe Trees generally grow on low moiſt Land in ſeveral Parts of *America*.

In *Europe* this Tree is preſerved by ſome curious Perſons who cultivate tender exotick Plants. It is propagated by Seeds, which ſhould be ſown on a Hot-bed early in the *Spring*; and when the Plants are come up, they ſhould be each tranſplanted into a ſeparate ſmall Pot, filled with rich Earth, and then plunged into a moderate Hot-bed of Tanners-bark; obſerving to ſhade them from the Sun every Day until they have taken new Root; after which time, they muſt be treated in the ſame Manner as hath been directed for the *Guanabanus*; with which Management, this Plant will thrive and make a Variety in the Stove, amongſt other tender exotic Plants.

TARRAGON: *vide* Draco Herba.

TAXUS, [ſo call'd of τόξα, *Poiſons*, becauſe this Tree in old time was uſed in compounding Poiſons, in warm Climates] The Yew-tree.

The *Characters* are;

It hath amentaceous Flowers, which conſiſt of many Apices, for the moſt part ſhaped like a Muſhroom, and are barren; but the Embryo's (which are produced at remote Diſtances on the ſame Tree) do afterwards become hollow, Bell-ſhaped Berries, which are full of Juice, and include Seeds ſomewhat like Acorns, having, as it were, a little Cup to each.

The *Species* are;

1. Taxus. *J. B.* The common Yew-tree.
2. Taxus *folio latiori, magiſque ſplendente. Boerh. Ind.* Yew-tree, with a broader and more ſhining Leaf.
3. Taxus *foliis variegatis. H. R. Par.* The Yew-tree, with ſtriped Leaves.

The two firſt Sorts are often promiſcuouſly cultivated in Gardens, without Diſtinction; but the third is preſerved by ſome for the ſake of its variegated Leaves: tho' there is very little Beauty in them; for during the *Summer* Seaſon, when the Plants are in Vigour, the Stripes in the Leaves are hardly to be perceived; but in *Winter* they are more obvious; however, the Stripe being rather a Blemiſh than any real Beauty, it is hardly worth preſerving.

There is hardly any Sort of ever-green Tree which has been ſo generally cultivated in the *Engliſh* Gardens, upon the account of its being ſo tonſile, as to be with Eaſe reduced into any Shape the Owner pleaſed; and it may be too often ſeen, eſpecially in old Gardens, what a wretched Taſte of Gardening did generally prevail, from the Monſtrous Figures of Beaſts, &c. we find theſe Trees reduced into; but of late this Taſte has been juſtly exploded by many Perſons of ſuperior Judgment: for what could be more abſurd than the former Methods of planting Gardens? where, in the Part next the Habitation, were crowded a large Quantity of theſe and other Sorts of ever-green Trees, all of which were ſheer'd into ſome trite Figure or other; which, beſides the obſtructing the Proſpect from the Houſe, occaſion'd an annual Expence, to render the Trees diſagreeable. For there never was a Perſon, who had conſider'd the Beauty of a Tree in its natural Growth, with all its Branches diffuſed on every Side, but muſt acknowledge ſuch a Tree infinitely more beautiful than any of thoſe ſhorn Figures, ſo much ſtudied by Perſons of a groveling Imagination.

The only Uſe I would recommend this Tree for in Gardens, is to form Hedges for the Defence of Exotick Plants, for which Purpoſe it is the moſt proper of any Tree in Being: the Leaves being ſmall, the Branches are produced very cloſely together, and if carefully ſhorn, they may be render'd ſo cloſe, as to break the Winds better than any other ſort of Fence whatever, becauſe they will not be reverberated, as againſt Walls, Pales, and other cloſe Fences, and ſo conſequently are much to be preferr'd for ſuch Purpoſes.

Theſe Trees may be eaſily propagated by ſowing their Berries in *Autumn*, as ſoon as they are ripe, (without clearing them from the Pulp which ſurrounds them, as hath been frequently directed) upon a Bed of freſh undung'd Soil, covering them over about half an Inch thick with the ſame Earth.

In the *Spring* the Bed muſt be carefully clear'd from Weeds, and if the Seaſon prove dry, it will be proper to refreſh the Bed with Water now and then, which will promote the Growth of the Seeds, many of which will come up the ſame *Spring*, but others will remain in the Ground until the *Autumn* or *Spring* following; but where the Seeds are preſerved above Ground till *Spring* before they are ſown, the Plants do never come up till the Year after; ſo that by ſowing the Seeds as ſoon as they are ripe, there is many times a whole Year ſaved.

Theſe Plants, when they come up, ſhould be conſtantly clear'd from Weeds, which, if permitted to grow amongſt them, would cauſe their Bottoms to be naked, and many times deſtroy the Plants, when they continue long undiſturb'd.

In this Bed the Plants may remain two Years; after which, in the *Spring* of the Year, there ſhould be a Spot of freſh undung'd Soil prepared, into which the Plants ſhould be removed the Beginning of *April*, placing them in Beds about four or five Feet wide, planting them in Rows about a Foot aſunder, and ſix Inches Diſtance from each other in the Rows; obſerving to lay a little Mulch upon the Surface of the Ground about their Roots, as alſo to water them in dry Weather until they have taken Root, after which they will require no farther Care, but to keep them clear from Weeds in *Summer*, and to trim them according to the Purpoſe for which they are deſign'd.

In theſe Beds they may remain two or three Years, according as they have grown, when they ſhould be again removed into a Nurſery, placing them in Rows at three Feet Diſtance, and the Plants eighteen Inches aſunder in the Rows, obſerving to do it in the *Spring*, as was before directed, and continue to trim them in the *Summer* Seaſon, according to the Deſign for which they were intended; and after they have continued three or four Years in this Nurſery, they may be tranſplanted where they are to remain; always obſerving to remove them in the *Spring*.

Theſe Trees are very ſlow in growing; but yet there are many very large Trees upon ſome barren cold Soils, in divers Parts of *England*: the timber of theſe Trees is greatly eſteem'd for many Uſes.

TELEPHIOIDES, Baſtard Orpine.

The *Characters* are;

It hath a Roſe-ſhap'd Flower, conſiſting of ſeveral Petals, which are conſtantly placed in a circular Order; from whoſe Empalement riſes the Pointal, which afterward becomes a roundiſh Fruit, divided into ſix Cells, each containing a ſingle Seed of the ſame Form with the Cell.

The *Species* are;

1. Telephioides *Græcum, humifuſum, flore albo. Tourn. Cor.* Low trailing Greek Baſtard Orpine, with a white Flower.
2. Telephioides *Americanum, erectum, folio ovali ſubtus glauco, flore herbaceo.* Upright American Baſtard Orpine, with an oval Leaf, which is of a Sea-green underneath, and an herbaceous Flower.
3. Telephioides *Americanum, arboreſcens, fructu parvo, foliis acuminatis. Houſt.* Tree-like American Baſtard Orpine, with a ſmall Fruit and pointed Leaves.
4. Telephioides *Americanum, arboreſcens foliis latis, ſubrotundis, & ſubtus incanis, fructu maximo. Houſt.* Tree-like American Baſtard Orpine, with broad roundiſh Leaves, which are hoary underneath, and the largeſt Fruit.
5. Telephioides *Americanum, arboreſcens, foliis latioribus ſubrotundis, fructu majore, ex longo pediculo pendulo. Houſt.* American Tree-like Baſtard Orpine, with broader roundiſh Leaves, and a larger Fruit hanging on long Footſtalks.

The firſt Sort was diſcovered by Dr. *Tournefort* in *Greece*; who conſtituted this Genus, giving it this Name from the Similitude there is between this Plant and the true Orpine of *Imperatus*. There is a low trailing Plant, which ſeldom continues more than two Years; it is propagated by Seeds, which ſhould be ſown in the *Spring* on a Bed of freſh Earth, where they are deſigned to remain; and when the Plants are come up, they ſhould be thinned where they are too cloſe, leaving them about ſix Inches aſunder; after this, they muſt conſtantly be kept clear from Weeds; in *July* the Plants will begin to flower, which are always produced behind the Leaves; and toward the latter End of *Auguſt* the Seeds will begin to ripen, and if they are not gathered as ſoon as ripe, the Pods will open and ſcatter them on the Ground, ſo that if they are not look'd after two or three times a Week, moſt of the Seeds will be drop'd; but the Plants will come up from theſe ſelf-ſown Seeds, and if they are kept clear from Weeds they will require no other Culture.

The ſecond Sort grows plentifully in *Barbadoes*, *Jamaica*, and ſeveral other Places in the *Weſt Indies*, where the Seeds ſcatter themſelves in ſuch Plenty, that in the Earth which is brought from thence, the Plants frequently come up, eſpecially if it be put on a Hot-bed, by which Method this Plant was firſt brought into *Europe*. This Sort grows erect, about two Feet high, and the Stem appears woody, but it ſeldom continues thro' the *Winter*, eſpecially if it has produced Seeds; ſo that I believe it to be annual; for the Plants which ariſe in the *Spring*, flower about *Midſummer*, and the Seeds ſoon after ripen; ſo that if they are not frequently look'd after, they are ſoon ſcattered; but the Seeds which fall into the Pots which are near the Plants, will come up the following *Spring*; ſo that when once the Plant is obtained, and permitted to ſhed its Seeds, there will be little Danger of loſing it, provided it is allowed a Place in the Hot-bed or the Stove, for it is too tender to thrive in the open Air in this Country.

The third Sort was diſcovered by the late Dr. *Houſtoun*, at *La Vera Cruz*, from whence he ſent the Seeds to *England*. This Sort riſes to the Height of eight or ten Feet, having a woody Stem; the Leaves are branched into many Wings, and the Flowers which are ſmall and of a whitiſh green Colour, grow on the Under-ſide of the Leaves, and are ſucceeded by ſmall Fruit, which hath not as yet ripened in *England*. The Leaves of this Plant fall off in *Winter*, and new ones come out the following *Spring*, ſo that for near four Months, the Plants are intirely deſtitute of Leaves.

The fourth and fifth Sorts were diſcovered by the late Dr. *Houſtoun* at *Campechy*; where they grow to the Height of twelve or fourteen Feet. The Leaves of theſe Kinds are broad, and come out alternately on the Branches. The Fruit of the fifth Sort is about the Size of a ſmall Nut, and is produced on the under-ſide of the Leaves, hanging on very long Foot-ſtalks. The Fruit of the fourth Sort is as large as Wallnuts, and hath hard woody Coverings or Shells. There are but few of theſe Seeds which come to Maturity in the Countries of their Growth; for I have examined many of the Fruit of both Kinds, and have not found one in forty of them which had perfect Seeds in them; ſo that whoever collects their Seeds abroad, ſhould throw them into Water, and take ſuch of them only, as ſink to the Bottom, for thoſe which ſwim on the Surface of the Water, ſeldom have any Kernels in them.

Theſe three Sorts are propagated by Seeds, (which muſt be procured from the Countries of their natural Growth, for they do not produce any Seeds in *England*) which ſhould be ſown on a Hot-bed early in the *Spring*, and when the Plants are come up, they ſhould be each tranſplanted in ſeparate ſmall Pots, filled with light freſh Earth, and then plunged into a moderate Hot-bed of Tanners-bark; being careful to ſhade them from the Sun every Day, until they have taken new Root; after which time they ſhould have freſh Air admitted to them every Day, by raiſing the Glaſſes of the Hot-bed in proportion to the Warmth of the Seaſon; and they muſt be frequently watered in hot Weather. In this Bed the Plants may remain till *Michaelmas*, when the Nights begin to be cold, at which time they ſhould be removed into the Stove, and plunged into the Bark-bed; where, during the *Winter* Seaſon, they muſt be kept very warm, otherwiſe they will not live in this Country. When the third Sort drops its Leaves, it ſhould be watered ſparingly, for if it hath too much Moiſture during the time it is deſtitute of Leaves, it very often periſhes. The fourth and fifth Kinds keep their Leaves throughout the Year; ſo theſe will require to be frequently refreſhed with Water, eſpecially if the Air of the Stove is kept warm. As theſe Plants are too tender to thrive in the open Air in this Country, even in the warmeſt Seaſon of the Year, ſo they ſhould be conſtantly kept in the Stove, and if they are continued in the Bark-bed, it will greatly promote their Growth. But in *Summer*, when the Weather is warm, they ſhould have a large Share of freſh Air admitted to them, by opening the Glaſſes of the Stove; and if their Leaves ſhould contract any Filth, they muſt be waſhed, otherwiſe it will retard the Growth of the Plants. When the Plants have filled the ſmall Pots with their Roots, they ſhould be ſhifted into Pots a little larger, which ſhould be filled with freſh light Earth; obſerving whenever the Plants are ſhifted to trim their Roots; and if their Leaves ſhould flag after being removed, it will be proper to ſhade them from the Sun for a few Days, until they have taken new Root. With this Management the Plants will thrive very faſt, and in three Years will produce their Flowers, when they will afford an agreeable Variety, being mixed with other tender exotic Plants.

TELEPHIUM, Orpine, or Live-long.

The *Characters* are;

It hath a Roſe-ſhap'd Flower conſiſting of ſeveral Leaves placed orbicularly; out of whoſe many-leav'd Empalement, riſes the Pointal, which afterward becomes a three-cornered Fruit, conſiſting of one Cell, which is filled with roundiſh Seeds. To theſe Notes ſhould be added, that the Leaves are placed alternately on the Branches.

The *Species* are;

1. TELEPHIUM *Dioſcoridis Imper.* The true Orpine of Dioſcorides, according to Imperatus.
2. TELEPHIUM *Americanum, portulacæ folio. Inſt. R. H.* American Orpine, with a Purſlain-leaf.
3. TELEPHIUM *maritimum, ſedi folio, flore rubello. Inſt. R. H.* Maritime Orpine, with a Houſeleek-leaf, and a red Flower.
4. TELEPHIUM *maritimum, ſedi folio, flore albo. Inſt. R. H.* Maritime Orpine, with a Houſeleek-leaf, and a white Flower.

The firſt Sort is a Native of *Italy*, *Spain*, and the ſouthern Parts of *France*, from whence the Seeds have been procured by ſome Perſons who are curious in Botany; who preſerve it in their Gardens for the Sake of Variety. It is a low Plant, whoſe Branches trail on the Ground; the Leaves are ſmall and roundiſh, of a glaucous Colour, and of a pretty thick Conſiſtence. The Flowers are ſmall, and of a whitiſh green Colour; ſo that the whole Plant makes but an ordinary Appearance.

This Sort may be propagated by Seeds, which ſhould be ſown early in the *Spring*, on a Bed of freſh light Earth, in an open Situation; and when the Plants are come up, they ſhould be thinned, ſo as to leave them ſix or eight Inches aſunder, and they muſt be conſtantly kept clear from Weeds; for if theſe are permitted to grow, they will ſoon overbear the Plants, and deſtroy them. In *June* they will begin to flower, and their Seeds will ripen in *Auguſt*; when they muſt be carefully watched to gather the Seeds, otherwiſe they will ſoon be ſcattered abroad; and if the Ground is not diſturbed, the Plants will come up in Plenty, and require no other Care, than to keep them clear from Weeds.

The ſecond Sort is a Native of *America*, from whence the Seeds have been brought to ſeveral curious Gardens in *Europe*. This a tender Plant, ſo the Seeds ſhould be ſown on a Hot-bed early in the *Spring*; and when the Plants are come up, they ſhould be each tranſplanted into a ſeparate ſmall Pot, filled with light freſh undunged Earth, and then plunged into a moderate Hot-bed of Tanners-bark; obſerving to ſhade them from the Sun in the middle of the Day for a little time, if the Weather ſhould prove hot, until they have taken new Root; after which time they ſhould have free Air admitted to them every Day, in Proportion to the Warmth of the Seaſon; and in hot Weather they muſt be frequently refreſhed with Water; but as the Leaves and Branches are ſucculent, ſo they ſhould not have too much Moiſture, leſt it rot them. In *July* the Plants will begin to flower, and in *September* the Seeds will ripen, and the Plants will periſh ſoon after, for they are annual; ſo that if the Plants are not brought forward early enough in the *Spring*, they will not produce good Seeds in this Country.

The third Sort was brought from the *Cape of Good Hope*, where it grows in great Plenty near the Sea Side. The fourth Sort is a Variety of the third, only differing in the Colour of its Flower. Theſe Sorts may be propagated by Seeds, which ſhould be ſown on a moderate Hot-bed in the *Spring*; and when the Plants are come up, they may be tranſplanted on another moderate Hot-bed, to forward their Growth; and when they are pretty ſtrong, they ſhould be each planted into a ſeparate Pot filled with freſh Earth, and placed on a gentle Hot-bed, to forward their making new Roots; and in *June* they ſhould be inured to bear the open Air by Degrees, into which they may be removed and placed in a warm Situation, amongſt *Ficoides*'s and other ſucculent Plants, which are Natives of the ſame Country; where they may remain till *October*, when they ſhould be removed into an airy Glaſs-caſe, where they may be treated in the ſame Manner as hath been directed for the *Ficoides*'s; with which Management theſe Plants will thrive very well. Theſe Plants may alſo be propagated by Cuttings, which may be taken from the old Plants during any of the *Summer* Months, and ſhould be laid to dry for a few Days before they are planted, in the ſame Manner as is practiſed for other ſucculent Plants; then they may be planted in a Bed of light Earth, where they will ſoon take Root, and may be planted afterwards in Pots, and treated as the ſeedling Plants.

TEREBINTHUS, The Turpentine-Tree.

The *Characters* are;

It is Male and Female in different Plants; the Flowers of the Male have no Petals, but conſiſt of a Number of Stamina *with Chives; the Embryo's which are produced on the Female Trees do afterwards become an Oval Fruit with a hard Shell, incloſing one or two oblong Kernels: to theſe Notes muſt be added, the Leaves are pennated, or wing'd, which are produced by Pairs, oppoſite, and end in a ſingle Lobe.*

The *Species* are;

1. TEREBINTHUS *vulgaris. C. B. P.* The common Turpentine-tree.
2. TEREBINTHUS *Indica Theophraſti, Piſtachia Dioſcoridis. Lob. Adv.* The Piſtachia-tree: *vulgo.*
3. TEREBINTHUS *peregrina, fructu majore, piſtachiis ſimile, eduli. C. B. P.* Foreign Turpentine-tree, with a larger eatable Fruit, like the Piſtachia-nut.
4. TEREBINTHUS *peregrina, fructu minore & cœruleo, eduli. C. B. P.* Foreign Turpentine-tree, with a ſmaller blue eatable Fruit.
5. TEREBINTHUS, *ſeu piſtachia trifolia. Inſt. R. H.* The three leav'd Turpentine or Piſtachia-tree.
6. TEREBINTHUS *Cappadocica. H. R. Par.* The Turpentine-tree of *Cappadocia.*
7. TEREBINTHUS *Americana, piſtachiæ fructu non eduli. Plum.* American Turpentine-tree, with a Fruit like the Piſtachia-nut, which is not eatable.
8. TEREBINTHUS *major, betulæ cortice, fructu triangulari. Sloan. Cat.* The greater Turpentine-tree, with a Bark like the Birch-tree, and a triangular Fruit, commonly called in the *Weſt-Indies* the Birch-tree.

The firſt and ſecond Sorts of theſe Trees are very common in ſeveral Iſlands of the *Archipelago*, from whence there are annually great Quantities of the *Piſtachia* Nuts brought into *England*, which do eaſily riſe if ſown on a Hot-bed in the *Spring*; ſo that the Trees of this Kind are much more common in *England* than are thoſe of the firſt Sort, whoſe Fruit are rarely brought over freſh: beſides, the Shells of theſe Nuts are much harder than thoſe of the *Piſtachia*, ſo that many times the Plants do not come up until the ſecond Year, which may alſo have contributed to the preſent Scarcity of the Plants in *England*.

The Seeds (or Nuts) of both theſe Trees ſhould be ſown in Pots fill'd with freſh light Earth, and plung'd into a moderate Hot-bed, obſerving to refreſh the Earth with Water frequently, as it may have Occaſion; and when the Plants are come up, (which thoſe of the *Piſtachia* will do in ſix Weeks after ſowing) they ſhould be inured to bear the open Air by degrees, into which they muſt be removed the Beginning of *June*, placing them where they may be ſcreen'd from the Violence of the Winds; in which Situation they may remain until *October*, when they ſhould be removed either into a common Hot-bed Frame, or elſe into a Green-houſe, where they may be defended from hard Froſt, but ſhould have as much free Air as poſſible in mild Weather, and muſt be frequently refreſh'd with Water.

In *March* following theſe Plants ſhould be removed, and each planted in a ſeparate Pot, fill'd with freſh light Earth, and as the *Spring* advances, ſo they ſhould be again removed into the open Air, and placed among other Exotick Plants, obſerving to water them frequently in dry Weather; and when their Roots are confined by the Smallneſs of the Pots, they muſt be ſhifted, being careful not to break the Earth off from their Roots, which will greatly injure them, unleſs it be done before the Plants begin to ſhoot in the *Spring*; for at that Seaſon they may be tranſplanted with as much Safety as any other deciduous Trees.

In this Manner theſe Plants ſhould be treated for three or four Years, while young; after which Time the *Piſtachia's* may be planted into the full Ground, obſerving to place them in a warm Situation, and dry Soil, where they will endure the Cold of our ordinary *Winters* very well, as may be ſeen by a very large Tree of this Kind, now growing in the Gardens of the Earl of *Peterborough*, at *Parſons-Green* near *Fulham*, which produces abundance of Fruit, without any manner of Care. Nor do I believe, but that the common *Turpentine-tree* would endure the Cold of our Climate, if after the Plants have acquired Strength, they are planted againſt a good Wall upon a dry Soil; for much Wet about the Roots of theſe Trees in *Winter*, is very often the Occaſion of their rotting, whereby the Trees are deſtroy'd.

The third, fourth and fifth Sorts grow in the eaſtern Countries, where their Fruit is eaten, but they are at preſent very rare in *Europe*. The ſixth Sort was originally brought from *Cappadocia*; the Fruit of this Sort is not eatable. Theſe Trees may be propagated as the two firſt and ſhould be treated in the ſame Manner as thoſe afterwards, for they are equally hardy, ſo will thrive in the open Air, if they are planted in a warm Situation. I ſaw young Plants of all theſe Kinds, in the Garden of the late Dr. *Boerhaave* near *Leyden*, which were growing in the full Ground, and had reſiſted the *Winters* Cold very well.

The ſeventh and eighth Sorts grow plentifully in the Iſland of *Jamaica*, and in ſeveral other Places in the *Weſt-Indies*; where the fifth Sort is called the *Hog-Doctor* or *Boar-tree*, and the eighth Sort is called the *Birch-tree*. Theſe Trees grow to the Height of thirty or forty Feet in the Places of their natural Growth, and have very large Trunks. The ſeventh Sort produces ſmall purple Flowers, at the Extremity of the Branches, which generally appear before the Leaves come out; for the Trees are deſtitute of their Leaves a conſiderable Time. From the Trunk and Branches of this Tree, there iſſues out a Balſam of the Conſiſtence and Smell of Turpentine, which is greatly uſed by the Inhabitants to heal green Wounds.

The eighth Sort produces ſmall purple Flowers at the Extremity of the Branches, which do generally precede the Leaves, like the other Sort; for the Leaves of this Tree fall off in *November*; and in *February* they put out new ones. The Trunk and Branches of this Tree being wounded, there flows out a liquid Balſam, which the Inhabitants call *Hoggum*, and make uſe of it to vomit or purge in chronical Diſeaſes; the uſual Doſe is a Quarter of an Ounce for a ſtrong Man, which is given in a Glaſs of Water, and will certainly vomit in a Quarter of an Hour after taking, without making the Perſon ſick, or cauſing any Uneaſineſs. The Inhabitants of *Jamaica* confidently affirm, that when the wild Hogs are wounded, they will repair to theſe Trees, and rub againſt the Trunks till the Balſam flows out; when they rub their wounded Part on the Balſam, which cures them; which occaſioned their calling it the *Hog-Doctor-tree*.

Theſe Trees may be propagated either by Seeds, or Cuttings; but the Seeds will not retain their growing Quality long, therefore they ſhould be put into a Box of Earth ſoon after they are ripe, and when the Plants are come up, and have obtained Strength, they may be brought to *England*; but there ſhould be great Care taken of them in their Paſſage, that they are not injured by ſalt Water; nor ſhould they have much freſh Water given to them, eſpecially as they come into a cooler Climate; for too much Moiſture will ſoon deſtroy them. In like manner alſo ſhould the Cuttings of theſe Trees be managed; for they ſhould be planted in Tubs of Earth, and kept in the Country until they are well rooted; for if they are ſent over before they have taken good Root, they ſeldom come good to *England*. When theſe arrive, they ſhould be each tranſplanted into ſeparate Pots, filled with freſh light Earth, and plunged into a moderate Hot bed of Tanners-bark; obſerving if the Seaſon is very warm, to ſhade them from the Sun in the Heat of the Day, and refreſh them every other Day with Water, but do not give it to them in great Quantities, leſt it rot their tender Roots. When the Plants have taken good Root, and recovered the Injuries they received in their Paſſage, they may be treated in the ſame Manner as is practiſed for other tender exotic Plants, keeping them conſtantly in the Bark-ſtove; for they are too tender to live in the open Air in this Country. During the *Winter* Seaſon, when they are deſtitute of Leaves, they ſhould have but little Water; but in the *Summer*, when the Weather is warm, they may have frequent Refreſhings, and a good Share of Air ſhould be admitted to them at that Seaſon. With this Management the Plants will thrive, and afford an agreeable Variety in the Stove, amongſt other Plants of the ſame Country.

TERGIFOETUS PLANTS, are ſuch as bear their Seeds on the Back-ſides of their Leaves.

TERRASSES: A *Terraſs* is a ſmall Bank of Earth, raiſed and trimm'd according to Line and Level, for the proper Elevation of any Perſon that walks round a Garden, that he may have a better Proſpect of all that lies round him; and theſe Elevations are ſo neceſſary, that thoſe Gardens that have them not, are deficient.

When *Terraſſes* are rightly ſituated, they are great Ornaments to ſuch Gardens as have them, for their Regularity and Opening, eſpecially when they are well built, and beautified with handſome Stairs, and fine Aſcents.

Sometimes under them are made Vaults, Grotto's, and Caſcades of Water, with an Order of Architecture, and a great many Statues in Niches; and on the Coping above are ſet Vaſes and Flower-pots, orderly ranged and diſpoſed.

There are ſeveral Kinds of *Terraſs* Walks:

1. The Great *Terraſs*, which lies next to the Houſe.
2. The Side or Middle *Terraſs*, which is commonly cut above the Level of the *Parterre*, *Lawn*, &c.
3. Thoſe *Terraſſes* which encompaſs a Garden.
4. Thoſe *Terraſſes* which lie under one another, being cut out of a large Hill; and theſe are different one from another, in ſome reſpect or other.

As to the Breadth of Side *Terraſſes*, this is uſually decided by its Correſpondence with ſome Pavilion or ſome little Jettee of Building; but moſt of all by the Quantity of Stuff that is to ſpare for thoſe Purpoſes.

The Side *Terraſs* of a Garden ought not to be leſs than twenty Feet, and but very ſeldom wider than forty.

As for the Height of a *Terraſs*, ſome allow it to be but five Feet high, but others more or leſs according to their Fancies; but the moſt exact Perſons never allow above three Feet and a half; and in a ſmall Garden, and a narrow *Terraſs* Walk, three Feet, and ſometimes two Feet and a half high, are ſufficient for a *Terraſs* eighteen Feet wide; and two Feet nine Inches is ſufficient for a *Terraſs* of twenty Feet wide; but when the Garden is proportionably large, and the *Terraſs* is thirty or forty Feet wide, then it muſt be at leaſt three Feet, or three Feet and a half high.

The nobleſt *Terraſs* is very deficient without Shade; for which Elm Trees are very proper: For no Seat can be ſaid to be complete, where there is not an immediate Shade almoſt as ſoon as out of the Houſe; and therefore theſe ſhady Trees ſhould be detached from the Body and Wings of the Edifice.

Terraſſes ſhould be planted rather with Elm or good Oak, than with Yew or Holly, that muſt be always clipping.

The Diſtance of the Elms acroſs, will be about twenty Feet, and they may be planted thirty Feet aſunder in Lines.

TERNATEA.

The *Characters* are;

It hath a papilionaceous (or Pea-bloom) Flower, whoſe Standard almoſt hides the Keel and the Wings; the Pointal afterwards becomes a Pod, which opens two Ways, and is filled with Kidney-ſhaped Seeds. To theſe Notes ſhould be added, that the Leaves are winged, and are terminated by an odd Lobe.

The *Species* are;

1. TERNATEA *flore ſimplici, cæruleo. Acad. Reg. Scien.* Ternatea, with a ſingle blue Flower.
2. TERNATEA *flore pleno, cæruleo. Acad. Reg. Scien.* Ternatea, with a double blue Flower.
3. TERNATEA *flore ſimplici albido. Acad. Reg. Scien.* Ternatea, with a ſingle white Flower.
4. TERNATEA *Americana, perennis, flore cæruleo. Houſt.* American perennial Ternatea, with a blue Flower.

The Name which Dr. *Tournefort* has given to this Genus of Plants is, from the Place whence theſe Plants were firſt brought, which is one of the *Molucca Iſlands*, called *Ternate*.

The three firſt-mentioned Sorts are annual Plants, which periſh ſoon after they have perfected their Seeds. But the fourth Sort will abide ſeveral Years, provided the Plants are placed in a warm Stove. They are all of them tender Plants; ſo their Seeds ſhould be ſown on a Hot-bed early in the *Spring*; and when the Plants are come up, they ſhould be each tranſplanted into a ſeparate ſmall Pot, filled with freſh light Earth, and then plunged into a moderate Hot-bed of Tanners-bark; obſerving to ſhade them from the Sun, until they have taken new Root, and often refreſh them with Water. As theſe Plants have very ſlender Branches, ſo they twiſt round whatever Plants grow near them; therefore they ſhould have Sticks thruſt into the Pots, for them to twine round, that they may be ſupported from trailing on the Ground. In warm Weather theſe Plants ſhould have a large Share of free Air admitted to them, otherwiſe they will draw up too weak; and when they are grown ſo tall, as to reach the Glaſſes of the Hot-bed, they ſhould be taken out, and (after having ſhifted them into larger Pots) they ſhould be plunged into the Bark-bed in the Stove, where they ſhould remain, to flower and perfect their Seeds.

The Flowers of the firſt and ſecond Sorts are of a very deep blue Colour, and if put in Water and macerated, will dye the Water almoſt as blue as *Indigo*. The ſecond Sort, having very double Flowers, makes a fine Appearance when it is in flower; ſo is worthy of a Place in every good Garden, where there is Conveniency for bringing them to Perfection. For as they are very tender, ſo if they are not brought forward early in the *Spring*, and carefully treated afterward, they will not perfect their Seeds in this Country.

The third Sort differs from the firſt only in the Colour of the Flower, ſo may be admitted for the ſake of Variety, tho' the Flowers are not near ſo beautiful.

The fourth Sort was diſcovered by the late Dr. *William Houſtoun* in *Jamaica*, from whence he ſent the Seeds to *England*. This is an abiding Plant, which rarely produces any Flowers in this Country; for from ſeveral of theſe Plants, which have been raiſed in the Phyſic-garden, there has but one of them produced any Flowers as yet, and that not more than three Flowers, tho' it has remained ſeveral Years.

TERRENE, Earthy, or compoſed of Earth.

TERRESTRIAL, Earthy, or that belongs to Earth.

TETRAGONOCARPOS.

The *Characters* are;

It hath an apetalous Flower, whoſe Empalement is divided into four Parts; in the Middle of the Flower riſes the Pointal, which afterwards becomes a Fruit, having four Wings, or Corners, and four Cells; in each of which is contained one Seed.

The *Species* are;

1. TETRAGONOCARPOS *Africana, fruticans, foliis longis & anguſtis. H. Amſt.* African ſhrubby Tetragonocarpos, with long, narrow Leaves.
2. TETRAGONOCARPOS *Africana, folio portulacæ longo, flore herbaceo. Boerh. Ind. Alt.* African Tetragonocarpos, with a long Purſlain Leaf, and an herbaceous Flower.

The firſt of theſe Plants is pretty common in the *Engliſh* Gardens, where there are Collections of rare Plants. This may be propagated by Cuttings, which ſhould be cut off from the Plant a few Days before they are planted, that the Part where they are cut may be healed, otherwiſe they will rot; for the Leaves and Stalks of this Plant are very full of Moiſture. The beſt Time to plant theſe Cuttings is in *July*, that they may have Time to make good Roots before *Winter*. Theſe Cuttings may be planted on a Bed of freſh Earth; and if the Cuttings are ſhaded from the Sun in the Heat of the Day, it will be of Service to them. They ſhould be frequently refreſhed with Water; but they muſt not have it in too great Plenty, for that will rot them. In about ſix Weeks after Planting, the Cuttings will be ſufficiently rooted to tranſplant; therefore they ſhould be taken up, and planted into Pots, filled with light, freſh, undunged Earth, and placed in a ſhady Situation, until they have taken new Root; after which Time they may be placed with other hardy exotick Plants, in a ſhelter'd Situation, where they may remain till the Middle or latter End of *October*; at which Time they ſhould be removed into the Greenhouſe, and placed where they may enjoy as much free Air as poſſible in mild Weather; for they only require to be protected from the Froſt, being pretty hardy with reſpect to Cold; but they ſhould not have too much Moiſture in *Winter*. If theſe Plants are planted in the full Ground in the *Summer* Seaſon, they will grow prodigiouſly rank and large, as they alſo will if they are permitted to root into the Ground, through the Holes at the Bottom of the Pots; therefore the Pots ſhould be frequently removed to prevent it; for when they grow too freely, their Leaves will be very full of Moiſture; which, together with the Weight of the Fruit, which are always produced at the Extremity of the Branches, will weigh the Branches upon the Ground, and render the Plants very unſightly. The Plants of this Kind commonly grow very ſtraggling; therefore the more their Roots are confined in the Pots, the more cloſe and ſtunted will be the Heads of the Plants, which is what they ſhould always be kept to, in order to render them ſightly. The Flowers of this Plant have no great Beauty, but as the whole Face of this Plant is peculiar, ſo it may be allowed a Place in every Collection of Plants, for the ſake of Variety, ſince it requires no great Trouble to cultivate it.

This Plant may alſo be propagated by Seeds, which ſhould be ſown on a warm Border of light freſh Earth, where ſometimes they will remain a whole Year before the Plants come up; therefore, when they do not come up the firſt Seaſon, the Borders ſhould not be diſturbed, but kept conſtantly clear from Weeds; and when the Plants are come up about four Inches high, they ſhould be taken up and planted in Pots, (and treated in the ſame Manner as hath been directed for the Cuttings) for if they are ſuffered to grow in the Border till they are large, they will not tranſplant ſo well, nor will they make ſo handſome Plants.

The ſecond Sort is leſs common in the *Engliſh* Gardens than the former; but in ſome of the Gardens in *Holland* it is in great Plenty. This may be treated in the ſame Manner as the firſt Sort, and is equally hardy.

TETRAPETALOUS FLOWER, is one which is compoſed of only four ſingle Flower-leaves, called *Petala*.

TEUCRIUM, [takes its Name of King *Teucer*, who was the firſt amongſt the Antients, who brought this Plant into Uſe] Tree Germander.

The *Characters* are;

The Flower-cup is divided into five Parts at the Top, but is of the Bell-ſhaped Kind; the Flower has no Galea *or* Creſt, *but inſtead thereof, the* Stamina *occupy the upper Part; the Beard, or lower Lip, is cut into five Parts, the middle Segment being larger, is hollowed like a Spoon; in the Centre of the Flower riſes the Pointal, attended by four Embryo's, which afterwards become ſo many Seeds, ſhut up in a Husk, which was before the Flower-cup: To theſe Notes ſhould be added, the Flowers are produced from the Wings of the Leaves.*

The *Species* are;

1. Teucrium *multis. J. B.* Common Tree Germander.
2. Teucrium *Bæticum. Cluſ. Hiſt.* Spaniſh Tree Germander.
3. Teucrium *Bæticum, calice campanulato, folio eleganter variegato. Boerh. Ind.* Spaniſh Tree Germander, with a ſtriped Leaf.
4. Teucrium *Hiſpanicum, latiore folio. Inſt. R. H.* Spaniſh Tree Germander, with a broader Leaf.
5. Teucrium *ſupinum, perenne, foliis laciniatis. Inſt. R. H.* Low perennial Germander, with jagged Leaves.
6. Teucrium *ſupinum, annuum, Luſitanicum, foliis laciniatis. Inſt. R. H.* Low annual Portugal Germander, with jagged Leaves.
7. Teucrium *fruteſcens, ſtæchadis Arabicæ folio & facie. Tourn. Cor.* Shrubby Germander, with the Leaf and Face of Arabian Stæchas.
8. Teucrium *Orientale, latifolium, laciniatum flore parvo. Tourn. Cor.* Broad jagged-leafed Eaſtern Germander, with a ſmall Flower.
9. Teucrium *Orientale, anguſtifolium, laciniatum, flore magno, ſuave-rubente. Tourn. Cor.* Narrow jagged-leafed Eaſtern Germander, with a large ſoft-red Flower.
10. Teucrium *Orientale, anguſtifolium, laciniatum, flore magno, ſubcœruleo. Tourn. Cor.* Narrow jagged-leafed Eaſtern Germander, with a large blue Flower.
11. Teucrium *Hiſpanicum, ſupinum, humilius, verbenæ tenuifoliæ foliis. Jeſſieu.* Low trailing Spaniſh Germander, with Leaves like the narrow-leafed Vervain.
12. Teucrium *Creticum, odoratum, flore purpureo. H. R. Par.* Sweet Germander of Crete, with a purple Flower.
13. Teucrium *Americanum, halicacabos & alopecuroides. Plum. Cat.* American Tree Germander, like the Winter-Cherry and Fox-tail.
14. Teucrium *Americanum, chamædryos folio, flore albo. Houſt.* American Tree Germander, with a common Germander Leaf, and a white Flower.

The firſt Sort here mentioned was formerly preſerved in Green-houſes with great Care; but of late Years it hath been planted out into the open Air, and is found hardy enough to endure the Cold of our ſevereſt *Winters* without Shelter, provided it be planted on a dry Soil.

This may be propagated by planting Cuttings in the *Spring*, on a Bed of freſh light Earth, obſerving to ſhade and water them until they have taken Root, after which they will require no farther Care, but to keep them clear from Weeds until the following *Spring*, when they may be tranſplanted out into the Places where they are to remain, being careful in moving them not to ſhake off all the Earth from their Roots, as alſo to water them until they have taken freſh Root; after which the only Care they require, is to keep the Ground clean about them, and to prune off ſuch Shoots as are ill ſituated, whereby their Heads will appear more regular.

The *Spaniſh* Sort is tenderer than the former, though that will endure the Cold of our ordinary *Winters*, if planted on a dry Soil, and in a warm Situation; but in a ſevere hard Froſt it is often deſtroyed; for which Reaſon the Plants are generally preſerved in Pots, and removed into the Green-houſe in *Winter*. This is propagated in the ſame Manner as the former.

The Sort with ſtriped Leaves is leſs common than the plain, and is valued by thoſe that delight in variegated Plants. This is ſomewhat tenderer than the plain Sort, but may be propagated and preſerved in the ſame Manner, only obſerving to place it in a warmer Part of the Green-houſe in *Winter*.

There is no very great Beauty in theſe Plants; but they are preſerved, for the ſake of Variety, by thoſe who are curious in collecting the various Kinds of exotick Plants.

The fourth Sort is very like to the *Bætick* Tree-germander, from which it differs in the Leaves being broader, the Shoots ſtronger, and the young Shoots being whiter. This Sort may be propagated by Cuttings, which may be planted during any of the *Summer* Months, in a Bed of freſh Earth; obſerving to ſhade them from the Sun until they have taken Root, as alſo to refreſh them frequently with Water. When the Cuttings are well rooted, they ſhould be carefully tranſplanted, ſome of them into Pots, that they may be ſhelter'd in *Winter*, and others on a warm dry Border, where they will endure the Cold of our ordinary *Winters* very well, without any Covering. Theſe Plants, which are deſigned to live in the open Air, muſt be planted on a dry rubbiſhy Soil, in which they will grow more ſtunted, ſo will reſiſt the Froſt much better, than when they grow in a rich Soil, which cauſes them to be more luxuriant. Thoſe Plants which are planted in Pots ſhould be ſheltered under a Hot-bed Frame in *Winter*; where they may have a greater ſhare of Air than in a Green-houſe; for the Glaſſes ſhould not be put over them in mild Weather, theſe Plants only requiring to be protected from ſevere Froſt.

The ſeventh and twelfth Sorts are alſo ſhrubby Plants, which may be propagated, and treated in the ſame Manner as hath been directed for the firſt; with which Management theſe will thrive very well, and may be allowed to have a Place in the Garden, for the Sake of Variety.

The fifth Sort is a low trailing Plant, which puts out Roots from the Joints of the Stalks, whereby it may eaſily be propagated, as alſo from the Seeds, which require no farther Care, than to ſow them on a Bed of freſh Earth, in an open Situation; and when the Plants are come up, they muſt be kept clear from Weeds; and where they are too cloſe, ſome of them ſhould be drawn out to give Room for the others to grow. This Sort will ripen Seeds very well in this Country; and, if planted in a warm Situation, will endure the Cold of our ordinary *Winters* very well.

The ſixth, eighth, ninth, tenth and eleventh Sorts are annual Plants, of humble Growth. Theſe are propagated by Seeds, which ſhould be ſown on a Bed of freſh Earth in *March*, and when the Plants are come up, they muſt be thinned where they are too cloſe, and kept clear from Weeds, which is all the Culture they require; for as they are Plants which make no great Figure in a Garden, ſo they are not cultivated in great Plenty; a few Plants of each Sort, for the Sake of Variety, is as many as any curious Perſon commonly keeps. Theſe Plants will drop their Seeds, and the Plants will come up from the ſelf-ſown Seeds, full as well, if not better, than when they are ſown by Hand, ſo may be eaſily maintained.

The thirteenth Sort was diſcovered by Father *Plumier*, in the *French* Settlements in *America*; and the fourteenth was diſcovered by the late Dr. *Houſtoun*, at the *Havannah*; from whence he brought the Seeds to *England*. Theſe are both very tender Plants, ſo muſt be preſerved in a Stove, otherwiſe they will not live thro' the *Winter* in this Country. They may be propagated by Seeds, which ſhould be ſown on a moderate Hot-bed in the *Spring*; and when the Plants are come up, they ſhould be each tranſplanted into a ſeparate ſmall Pot, filled with freſh light Earth, and then plunged into a moderate Hot-bed of Tanners-bark, and ſhaded from the Sun in the Heat of the Day, until they have taken new Root; after which Time they ſhould have a large Share of free Air admitted to them in warm Weather, and muſt be plentifully watered. When theſe Plants are brought forward early in the *Spring*, ſome of them will produce their Flowers the ſame Seaſon, but they rarely produce ripe Seeds the firſt Year; ſo the Plants ſhould be removed into the Stove at *Michaelmas*, and during the *Winter* Seaſon, ſhould have a moderate Share of Heat, and will require to be frequently refreſhed with Water; but it muſt not be given to them in large Quantities when the Weather is cold, for that will often occaſion their Leaves falling off. Theſe Plants, which are preſerved thro' the *Winter*, will flower early the following *Spring*, and produce good Seeds; and the old Plants may be preſerved three or four Years, if they are conſtantly kept in a Stove.

THALICTRUM, [this Name is ancient, and written in a two-fold Manner; in the Manuſcripts ϑαλίγθρον and ϑαλίχτρον, but now it has obtain'd the Name of *Thalictrum* among all the Moderns, of ϑάλλω, to *grow green*: It was anciently uſed at Weddings: or becauſe of its green Leaves adorning Gardens, it is alſo call'd πήγανον, *i. e.* becauſe ſome Botaniſts have claſs'd this Plant with *Rues*] Meadow Rue.

The *Characters* are;

The Flower conſiſts of ſeveral Leaves placed orbicularly, which expand in form of a Roſe, in the Middle of which ariſe numerous Cluſters of Chives, encompaſſing the Pointal, which afterwards becomes a Fruit, in which are collected, as in a little Head, the Capſules, which are ſometimes wing'd, and ſometimes without Wings, each containing one Seed, for the moſt part oblong.

The *Species* are;

1. Thalictrum *Alpinum, aquilegiæ foliis, florum ſtaminibus purpuraſcentibus. Tourn.* Alpine Meadow Rue, with Columbine Leaves, and the Chives of the Flower of a purpliſh Colour, *commonly call'd* the Feather'd Columbine.

2. Thalictrum *Alpinum majus, aquilegiæ foliis, florum ſtaminibus albis, caule viridi. Tourn.* Greater Alpine Meadow Rue, with Columbine Leaves, white Chives to the Flowers, and a green Stalk.

3. Thalictrum *Canadenſe, caule purpuraſcente, aquilegiæ foliis, florum ſtaminibus albis. Tourn.* Canada Meadow Rue, with a purpliſh Stalk, Columbine Leaves, and white Chives to the Flower.

4. Thalictrum *Americanum minus. Park. Theat.* Leſſer American Meadow Rue.

5. Thalictrum *majus, ſiliquâ anguloſâ aut ſtriatâ. C. B. P.* Greater Meadow-rue, with an angular furrowed Pod.

6. Thalictrum *pratenſe, majus, Monſpelienſium, foliis rugoſis. H. R. Par.* Greater Montpelier Meadow-rue, with rough Leaves.

7. Thalictrum *majus, nonſtriatum. C. B. P.* Greater ſmooth Meadow-rue.

8. Thalictrum *majus, flavum, ſtaminibus luteis, vel glauco folio. C. B. P.* Greater yellow Meadow-rue, with yellow Chives, and a Sea green Leaf.

9. Thalictrum *magnum, flore luteo odorato. Vir. Luſit.* Great Meadow-rue, with a yellow ſweet Flower.

10. Thalictrum *minus, aſphodeli radice, parvo flore. Inſt. R. H.* Smaller Meadow-rue, with an Aſphodel-root, and a ſmall Flower.

11. Thalictrum *minus, aſphodeli radice, magno flore. Inſt. R. H.* Smaller Meadow-rue, with an Aſphodel-root, and a large Flower.

12. Thalictrum *minus. C. B. P.* Smaller Meadow-rue.

13. Thalictrum *pratenſe, anguſtifolium. C. B. P.* Narrow-leav'd Meadow-rue.

14. Thalictrum *pratenſe, anguſtiſſimo folio. C. B. P.* The narroweſt leav'd Meadow-rue.

15. Thalictrum *minus, alterum, Pariſienſium, foliis craſſioribus & lucidis. H. R. Par.* Another ſmall Meadow-rue of Paris, with thicker ſhining Leaves.

16. Thalictrum *minimum, fœtidiſſimum. C. B. P.* The leaſt and moſt ſtinking Meadow-rue.

17. Thalictrum *montanum, minus, foliis latioribus. Raij Syn.* Small Mountain Meadow-rue, with broader Leaves.

18. Thalictrum *minimum, montanum, atro-rubens, foliis ſplendentibus. Raij Syn.* Smalleſt Mountain Meadow-rue, with blackiſh-red ſhining Leaves.

The four firſt are all the Sorts which I have obſerved to be cultivated in the Flower-Gardens for their Beauty. They are commonly known by the Name of *Feather'd* or *Spaniſh Columbine* among the Gardeners, which Names, I ſuppoſe, they received from the Similitude that the Leaves of this Plant bear to thoſe of Columbine, tho' their Flowers are very different therefrom.

Theſe Plants are propagated by parting their Roots; the beſt Time for this Work is in *September*, when their Leaves begin to decay, that they may take freſh Root before the Froſt comes on to prevent them. They ſhould alſo be planted in a freſh light Soil, and have a ſhady Situation, in which they will thrive exceedingly; tho' they may be planted in almoſt any Soil or Situation, provided it be not too hot and dry. Theſe Roots ſhould not be parted or removed oftner than every other Year; but if they are permitted to ſtand three Years, they will flower much ſtronger for it.

They may alſo be propagated by ſowing their Seeds on an Eaſt Border, ſoon after they are ripe, obſerving to keep the Ground clear from Weeds; and the following *Spring* the Plants will come up, when they ſhould be frequently refreſh'd with Water, and conſtantly kept clean from Weeds: the *Autumn* following they may be planted out into Nurſery-beds, about five or ſix Inches aſunder, where they may remain until they have Strength enough to flower, when they ſhould be removed into the Borders of the Flower-Garden, placing them in the middle Line among Plants of large Growth, allowing them Room, otherwiſe they will ſpread over whatever Plants are near them.

Theſe Plants flower from the Beginning of *May* to the Beginning of *June*, and if the Seaſon be moderate, they will continue in Beauty a long time: this, together with their being hardy Plants, which require little Culture, renders them worthy of a Place in every good Flower-Garden; and their Flowers are very proper to intermix with others, for Baſons to adorn Halls, Chimnies, &c. in the *Summer* time.

The fifth Sort grows plentifully in moiſt Meadows, in diverſe Parts of *England*: The ſixth Sort is found growing wild about *Newmarket*, and on chalky Grounds in ſeveral Parts of *England*. The ſeventeenth and eighteenth Sorts, grow wild on the rocky Mountains of *Wales*, from whence they have been tranſplanted into ſome curious Gardens, where they are preſerved for the ſake of Variety.

The other Sorts are not Natives of *England*, yet they are equally hardy with the former, ſo will thrive in the open Air very well. Moſt of theſe Plants have creeping Roots, by which they ſpread very far, and may be eaſily propagated; but they ſhould not be planted amongſt other better Plants, becauſe theſe will overbear and deſtroy them. Theſe Plants ſhould be planted in a moiſt Soil, otherwiſe they will not flower very ſtrong. The beſt time to tranſplant them, is about *Michaelmas*, that they may be well rooted before the dry Weather comes on in the *Spring*.

The fifth, ſixth, ſeventh, eighth, ninth, thirteenth and fourteenth Sorts, are tall Plants, ſo may be planted amongſt other Plants of the ſame Growth, which delight in a moiſt Soil, in ſome obſcure Part of the Garden, where better things will not thrive; in which Places theſe will thrive and flower, and maintain themſelves without any other Care, but to keep them clear from very large Weeds, which would overbear and deſtroy them.

The other Sorts are of humble Growth, ſome of them ſeldom riſing above ſix Inches high, and the others not more than a Foot; ſo theſe may be planted in ſhady Borders with other hardy Plants, where they will thrive very well, provided they are watered in dry Weather, and will abide ſeveral Years. All theſe Sorts do flower in *May* and *June*, and their Seeds are ripe toward the end of *Auguſt*. But as theſe do propagate ſo faſt by their Roots, ſo they are rarely raiſed from Seeds, which is a more tedious Method, for it is commonly three Years before the ſeedling Plants produce their Flowers ſo ſtrong as the old ones.

THAPSIA, [ſo call'd of the Iſland *Thapſus*, where it grew in Plenty] Scorching Fennel, *or* Deadly Carrot.

The *Characters* are;

It hath an umbellated Roſe-ſhap'd Flower, conſiſting of five Petals, which are placed in a circular Order, and reſt on the Empalement, which afterwards become a Fruit, compoſed of two long furrowed Seeds, which have a large leafy Border.

The *Species* are;

1. Thapsia *maxima, latiſſimo folio. C. B. P.* The greateſt Scorching-fennel, with a very broad Leaf.

2. Thapsia *latifolia, villoſa. C. B. P.* Broad-leav'd hairy Scorching-fennel.

3. Thapsia *foliis Libanotidis, fœtidiſſima. C. B. P.* The moſt ſtinking Scorching-fennel, with Herb-Frankincenſe-leaves.

4. Thapsia *apii folio, Luſitanica, fœtidiſſima, flore albo. Inſt. R. H.* The moſt ſtinking Portugal Scorching-fennel, with a Smallage-leaf, and a white Flower.

5. Thapsia *tenuiore folio, Apula. Inſt. R. H.* Apulian Scorching-fennel, with a narrow Leaf.

6. **Thapsia**, *ſive Turbith Garganicum, ſemine latiſſimo. J. B.* Scorching-fennel, with very broad Seeds, whoſe Roots were ſuppoſed to be the Turbith.

7. **Thapsia** *Alpina, lucida, Thalictri aut Carotæ folio, flore albo. Bocc. Muſ.* Shining Scorching-fennel of the Alps, with a Meadow-rue or Carrot-leaf, and a white Flower.

8. **Thapsia** *Thalictri folio, Luſitanica, villoſa. Inſt. R. H.* Hairy Portugal Scorching-fennel, with a Meadow-rue-leaf.

9. **Thapsia** *Orientalis, Anethi folio, ſemine eleganter crenato. Tourn. Cor.* Eaſtern Scorching-fennel, with a Dill-leaf, and Seed beautifully notched.

10. **Thapsia** *Orientalis, aquatica, Angelicæ folio. Tourn. Cor.* Eaſtern Water Scorching-fennel, with an Angelica-leaf.

11. **Thapsia** *Cretica, Thalictri folio, villoſa, ſeminum alis purpuro-violaceis. Tourn. Cor.* Hairy Scorching-fennel of Crete, with a Meadow-rue-leaf, and Seeds with purple Violet Borders.

12. **Thapsia** *Carotæ folio. C. B. P.* Scorching-fennel, with a Carrot-leaf.

The firſt Sort grows plentifully in ſeveral Parts of *Spain*, and on the *Pyrenees*, where the Inhabitants ſometimes uſe the Roots in Medicine; but it purges upwards and downwards, with ſo much Violence, that it frequently puts thoſe who take it in great Hazard of their Lives.

The ſixth Sort, whoſe Roots have by ſome Botaniſts been ſuppoſed to be the *Turbith* of the Shops, grows on the Coaſt of *Africa*; from whence the Seeds have been brought into ſeveral curious Gardens in *Europe*, where the Plant is preſerved by thoſe who delight in Botany.

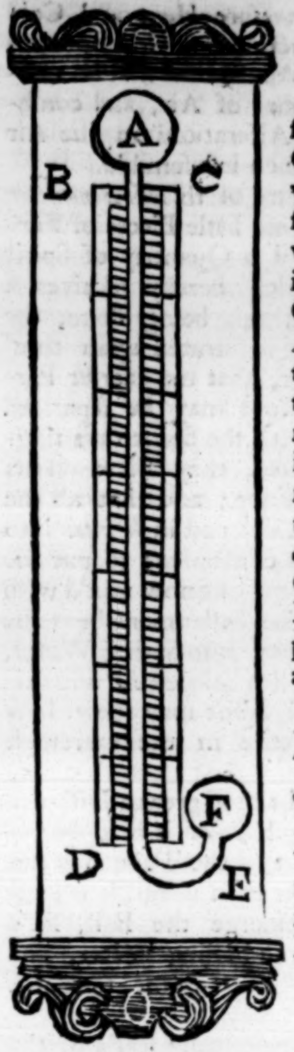
The twelfth Sort is mentioned in the Catalogue of Plants inſerted in the College Diſpenſatory, but is rarely uſed in Medicine; for it is of ſuch an acrid burning Quality, that it is very dangerous to take inwardly; but outwardly applied, it takes off Blemiſhes and Scabs from the Skin.

All theſe Plants are very hardy with reſpect to Cold, ſo that they will thrive in the open Air in this Country; but they ſhould have a loamy Soil, and in dry Weather ſhould be watered, otherwiſe their Flowers will fall off, without producing good Seeds. Theſe Plants are only propagated by Seed, which ſhould be ſown in *Autumn*; for if they are kept out of the Ground till *Spring*, they often miſcarry; or if they do grow, they commonly lie in the Earth a whole Year before the Plants come up; whereas thoſe Seeds which are ſown in *Autumn*, generally grow the following *Spring*. Theſe ſhould be ſown in Drills, in the Place where they are deſigned to remain; the Drills ſhould be at leaſt two Feet aſunder, becauſe the Plants ſpread their Leaves very wide. When the Plants come up in the *Spring*, they muſt be carefully clear'd from Weeds; and where they are too cloſe together, ſome of them ſhould be drawn out, to give Room for the others to grow; but at this time they need not be left more than two or three Inches apart. For the firſt Year the Plants ariſe from Seeds, they make but ſlow Progreſs; ſo the *Autumn* following, the remaining Part of the Plants may be taken up, leaving thoſe which are deſigned to remain, about eighteen Inches aſunder; and thoſe Plants which are taken up, may be tranſplanted into another Bed, if they are wanted. After the firſt Year theſe Plants will require no farther Care, but to keep them clear from Weeds; and every *Spring*, juſt before the Plants begin to puſh out new Leaves, the Ground ſhould be carefully dug between the Plants to looſen it; but the Roots muſt not be injured, leſt it ſhould cauſe them to decay. The Plants being thus managed, will continue ſeveral Years, and produce Flowers and Seeds annually, from which new Plants may be raiſed.

THERMOMETER, [Θερμόμετερ, of θερμὴ, *Heat*, and μετρέω to *meaſure*] An Inſtrument ſhewing, or rather meaſuring, the Increaſe and Decreaſe of the Heat and Cold of the Air.

Of which there are various Kinds; the Conſtructions, Defects, Theories, *&c.* whereof are as follow.

The Conſtruction of a Thermometer *depending on the Rarefaction of the Air.*

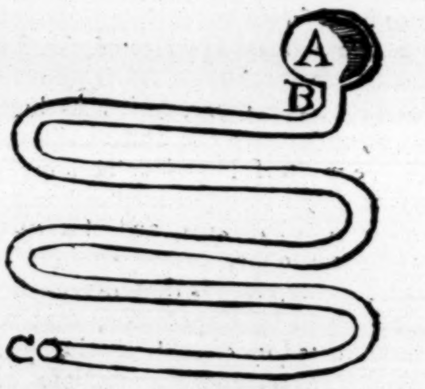


In the Tube A F, to which is faſten'd a Glaſs Ball A C, is put a Quantity of common Water, mix'd with *Aqua Regia*, to prevent its freezing; and the Mixture ting'd with a Solution of Vitriol, to give it a Greenneſs. In filling the Tube, Care is taken that there be ſo much Air left in the Ball and Tube, as that when at its greateſt Condenſation, in the Middle of *Winter*, it may juſt fill the Ball; and yet in its greateſt Rarefaction in *Summer*, may not drive all the Liquor out of the Tube. To the other Extreme of the Tube is faſten'd another Glaſs Ball, EF, open to the Air at F. On each Side the Tube is applied the Scale B D, divided into any Number of equal Parts.

Now, as the ambient Air becomes warmer, the Air in the Ball and the Top of the Tube expanding, will drive the Liquor into the lower Ball, and conſequently its Surface will deſcend; on the contrary, as the ambient Air grows colder, that in the Ball becoming condenſed, the Liquor will aſcend.

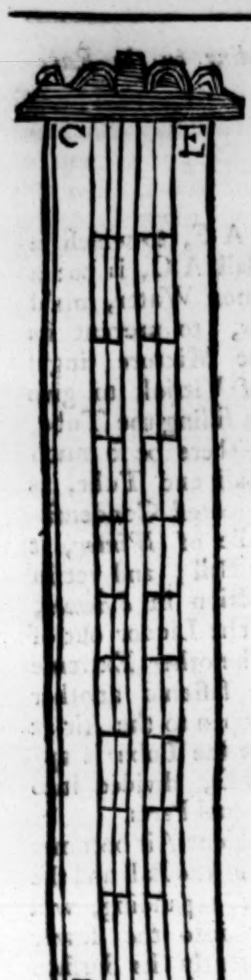
The Conſtruction of the Mercurial Thermometer.

In the ſame Manner, and with the ſame Caution as before, put a little Quantity of Mercury, not exceeding the Bigneſs of a Pea, into a Tube BC, thus bent with Wreaths, that taking up the leſs Height, it may be the more manageable, and leſs liable to Harm; divide this Tube into any Number of equal Parts, to ſerve for a Scale.



Here the Approaches of the Mercury towards the Ball A will ſhew the Increaſes of the Degree of Heat. The Reaſon is the ſame as in the former.

But both theſe Inſtruments are defective in this, that they are liable to be acted on by a double Cauſe: for not only a Decreaſe of Heat, but alſo an Increaſe of Weight of the Atmoſphere, will make the Liquor riſe in the one, and the Mercury in the other; and on the contrary, either an Increaſe of Heat, or Decreaſe of Weight of the Atmoſphere, will make it deſcend.



There being ſome Inconveniences attending the *Thermometers* juſt deſcribed, another has been attempted, that ſhould meaſure Heat and Cold by the Rarefaction and Condenſation of Spirits of Wine, tho' that be vaſtly leſs than that of Air, and conſequently the Alterations in the Air likely to be much leſs ſenſible.

The Structure of this *Thermometer* is this: On ſome little Pieces of *Turmerick* is pour'd a Quantity of Spirit of Wine, which hereby receives a red Tincture; this being done, the Spirit of Wine is filtrated again thro' a brown Paper, that the coarſer Particles of the Root may be ſeparated therefrom: with the Spirit thus tinged and prepared, they fill a Glaſs Ball with a Tube; and that all the Spirit may not deſcend in *Winter* into the Ball, it is convenient to put the Ball into a Lump of Snow mix'd with Salt; or, if the Inſtrument be to be made in *Summer*, into Spring Water, impregnated with Saltpetre; and that the condenſed Spirit may ſhew how far it will retire in the extremeſt Cold.

If it be ſtill at too great a Diſtance from the Ball, Part of it is to be taken out; and that the Tube may not be much longer than needs, it is convenient to immerge the Ball, fill'd with its Spirit, in boiling Water, and to mark the fartheſt Point to which the Spirit then riſes.

At this Point the Tube is to be hermetically ſeal'd by the Flame of a Lamp, and at the Sides is to be added a Scale, as in the former *Thermometers*.

Now the Spirit of Wine rarefying and condenſing very conſiderably, as the Heat of the ambient Air increaſes, the Spirit will dilate, and conſequently will aſcend in the Tube; and as the Heat decreaſes, the Spirit will deſcend, and the Degree or Quantity of Aſcent and Deſcent will be ſeen in the Scale.

Yet as the *Ratio* of Yeſterday's Heat to To-day's is not hereby diſcover'd, this Inſtrument is not ſtrictly a *Thermometer* any more than the former.

Here it is to be obſerv'd;

1. That as the natural Gravity of the Liquor makes it tend downwards, ſo it reſiſts its Aſcent out of the Ball into the Tube, and that the more, as it riſes higher; for which Reaſon it were beſt to have the Tube horizontal.

2. Since there muſt of Neceſſity be ſome Air left in the void Part of the Tube over the Liquor, that Air, by its Elaſticity, will tend downwards, and of conſequence will reſiſt the Riſe of the Liquor, and be compreſs'd by it as it does riſe; its Elaſticity therefore is thus increaſed.

3. Since it is found by Experience, that a leſs Degree of Heat is communicated more eaſily to the Spirit of Wine in the Ball than a greater, the Rarefactions of the Spirit of Wine are not proportionable to their producing Cauſes; eſpecially a greater Degree of Heat finds more Liquor in the Tube than a leſs does, to which, notwithſtanding, the Heat may be more eaſily communicated than to that ſtagnating in the Ball.

On theſe Accounts, this laſt *Thermometer*, call'd the *Florentine Thermometer*, (becauſe contrived by the *Academiſts del Cimento*) tho' it is that which is in common Uſe, is far from being an accurate Meaſure of Heat, *&c.* To which may be added, what Dr. *Halley* obſerves in the *Philoſophical Tranſactions*, That he has learn'd from thoſe that have kept Spirit of Wine long, that it loſes Part of its expanſive Force in Courſe of Time.

Various Authors have propoſed various Methods for finding a fix'd Point or Degree of Heat and Cold, from which to account for the other Degrees, and adjuſt the Scale; ſo that Obſervations made at the ſame or different Times, in different Places, may be compared together.

Some note the Place the Liquor is at in *Winter*, when Water begins to freeze; and again that in *Summer*, when Butter placed near the Ball of the *Thermometer* melts: the intermediate Space they divide into two equal Parts; the middle Point whereof anſwers in their Graduation to temperate Heat; and each Moiety they ſubdivide into ten Degrees, adding four other equal Degrees on each of the two Extremes.

But this Method ſuppoſes the ſame Degree of Heat and Cold to anſwer to the freezing of all Water, and the melting of all Butter, as alſo that all *Thermometers* receive the ſame Impreſſions from the ſame Degree of Heat: all which are contrary to Experience.

Others adviſe, That the Ball of the *Thermometer* be put into a Quantity of *Snow* and *Salt*, and the Point the Liquor is at to be noted; and that thence the *Thermometer* be removed into a deep Cave or Cellar, whither no external Air reaches, ſo that the Liquor receiving the Action of the temperate Air, may ſhew the Degree of temperate Heat. And laſtly, they divide the intermediate Space into fifteen or more equal Parts, which they continue beyond each Extreme: but this Method is liable to the like Inconvenience with the former.

Dr. *Halley* aſſumes *that* for a fix'd Degree of Heat, where Spirits of Wine begin to boil; but there is Reaſon to ſuſpect this too, of being precarious: tho' after him, M. *Amontons* retains the Degree of Heat, anſwering to boiling Water, for the graduating his Mercurial *Thermometer*. But as the different ſpecifick Gravities of Water argue a different Maſs and Texture, it is highly probable, that Heat of all boiling Waters is not the ſame; ſo that the Point is yet undetermin'd.

THERMOSCOPE, [of Θερμη, *Heat, and* σκοπεω, *I view*] An Inſtrument deſign'd to ſhew the Changes happening in the Air, with reſpect to *Heat* and *Cold*.

The Name of *Thermoſcope* is indifferently uſed with that of *Thermometer*: however, there is ſome Difference in the literal Import of the Words; the firſt ſignifying an Inſtrument that ſhews or exhibits the Changes of Heat, *&c.* to the Eye; and the latter, an Inſtrument that meaſures thoſe Changes: on which Foundation the *Thermometer* ſhould be a more accurate *Thermoſcope*.

This Difference the excellent *Wolfius* taking hold of, deſcribes all the *Thermometers* in Uſe as *Thermoſcopes*; ſhewing, that none of them do properly meaſure the Changes of Heat, *&c.* and that none of them do more than indicate the ſame.

Tho' their different Heights, Yeſterday and To-day, ſhew a Difference of Heat; yet ſince they don't diſcover the *Ratio* of Yeſterday's Heat to To-day's, they are not ſtrictly *Thermometers*.

The *Acta Erud. Lipſ.* propoſes a Method of graduating the common *Thermometers* ſo, as that the unequal Diviſions thereof ſhall correſpond to equal Degrees of Heat; whereby the *Ratio* of To-day's Heat to Yeſterday's will be meaſured, and conſequently the *Thermoſcope* improv'd into a *Thermometer*.

The Method is thus:

Take a ſlender Tube about four Palms long, with a Ball faſten'd to the ſame; pour into it Spirit of Wine, enough juſt to fill the Ball, when ſurrounded with Ice, and not a Drop over: in this State ſeal the Orifice of the Tube hermetically, and provide ſix Veſſels, each capable of containing a Pound of Water, and ſomewhat over; and into the firſt pour eleven Ounces of warm Water, into the ſecond ten Ounces, into the third nine, *&c.*

This done, immerge the *Thermometer* into the firſt Veſſel, and pour into it one Ounce of hot Water, obſerving how high the Spirit riſes in the Tube, and noting the Point with an Unit; then remove the *Thermometer* into the ſecond Veſſel, into which are pour'd two Ounces of hot Water, and note the Place the Spirit riſes to with two: by thus proceeding, till the whole Pound of Water is ſpent, the Inſtrument will be found to be divided into twelve Parts, denoting ſo many Terms or Degrees of Heat; ſo that at two, the Heat is double to that of one; at three, triple, *&c.*

But *Wolfius* ſhews, that tho' this Method is plauſible, yet it is deceitful, and built on falſe Suppoſitions; for it takes for granted, we have one Degree of Heat, by adding one Ounce of hot to eleven of cold Water, two Degrees by adding two Ounces to ten, *&c.* It ſuppoſes that a ſingle Degree of Heat acts on the Spirit in the Ball of a ſingle Force, a double with a double Force, *&c.*

Laſtly, it ſuppoſes, that if the Effect be produced in the *Thermometer* by the Heat of the ambient Air, which is here produced by the hot Water, the Air has the ſame Degree of Heat with the Water.

But none of theſe Suppoſitions are true: For, as to the firſt; allowing the Heat of the hot Water equally diſtributed thro' the Cold, one Degree of Heat will be diſtributed thro' eleven Parts, two thro' ten, three thro' nine, *&c.*

taking therefore equal Bulks of Water, *ex. gr.* a twelfth Part of each, the Heat will not be double in the one, triple in another, *&c.*

The firſt Suppoſition is therefore erroneous, and ſo is the ſecond; for neither is the Heat of the hot Water equally diffuſed thro' the Cold; nor does the Heat of the hot Water act uniformly on the Spirit of Wine, *i. e.* not with the ſame Force all the Time of its Action.

For the third Suppoſition: The Heat of the ambient Air acts not only on the Spirit of Wine in the Ball, but alſo on that in the Tube, and therefore This as well as That will be changed.

Dr. *Hook*, in order to adjuſt the Gradations of a *Thermometer* with the greater Accuracy, hath contrived and deſcribed an Inſtrument for that Purpoſe, in his *Micrographia*, *p.* 38.

The Way of filling *Thermoſcopes*, or ſuch other ſmall Glaſs Tubes with Spirit of Wine or Water.

Take the Ball of the Glaſs, and then warm it gently between your Hands; then heat it very well (tho' gently) before a good Fire, turning it round, that it may be equally warm; for without this Caution there will be Danger of its breaking: then applying the Ball to the Flame of a Lamp or Candle, turning it about in it, heat it as hot as you can, without melting the Glaſs; and then ſpeedily immerſing the open End of the Pipe into the Veſſel of that Liquor you intend to fill it withal, the Liquor will riſe into it, and fill it near full.

The Reaſon of which Aſcent of the Liquor is, that the Air within the Ball and the Tube being expell'd in great meaſure by the Heat, or at leaſt rarefy'd there to a very great Degree, the immerſed open End of the Tube keeps off the Preſſure of the circumambient Atmoſphere on that Part of the Liquor that the End of the Tube covers: but the Atmoſphere preſſes on all other Parts of the Liquor in the open Veſſel; and conſequently, (there being none, or a very ſmall Quantity of Air within the Tube to hinder it) forces it by its Weight up into the Tube, till it gain an Equilibrium with the Preſſure or Weight of the Air without.

If the Tube cannot be fill'd full enough by this Method, the reſt may be ſupplied by a ſmall Glaſs Funnel, the Shank of which muſt be drawn out exceeding ſlender, and inſerted into the Orifice of the Tube; and then by blowing, you may force by your Breath the Spirit of Wine into the Tube, ſo as to fill it quite, or to what Degree you pleaſe.

Dr. *Hook*, in his *Micrographia*, hath an Engine for graduating his *Thermometers*, to make them true Standards of Heat and Cold.

The *Thermometers* or *Thermoſcopes* are Inſtruments of very great Uſe to Gardeners in the Management of Hot-beds or Stoves. They ſhew, by Inſpection, the preſent Condition of the Air, and whether it be *hot* or *cold*; which Day in *Summer* is the *hotteſt*, and in the *Winter* which is the *coldeſt*, or any Part of the Day: and from thence many uſeful Experiments have, and may be made; *viz.* how much one *Spring* exceeds another in Coldneſs; which *Baths* are the hotteſt or coldeſt: and if being held in the Hand of a Perſon in a Fever, or otherwiſe applied, will nicely ſhew the Abatement or Increaſe of a Fever.

Mr. *Telende* makes uſe of a *Thermometer* that has a long Tube of about two Feet in Length, and is about the eighth Part of an Inch diameter; and in this he has remarked, that the Air is cold for his Plants when the Spirit riſes to fifteen Inches; that it is temperate at ſixteen Inches and a half; that the Air is warm when it riſes to eighteen Inches: And this is the Standard for his *Pine-apple* Heat. It is marked for *hot Air* at twenty Inches, and *ſultry hot* at twenty-one and a half; but in the common *Engliſh Thermometers*, theſe Degrees are differently marked; his *temperate Air* is about our *warm*; his *warm Air* our *hot*; and our *hot* Air is about the ſame as his *ſultry*.

He has directed ſome *Thermometers*, *&c.* to be made for both Hot-beds and Stoves, by which a Perſon may be at once apprized of the Degree of Heat under the Line, and of the ſeveral Degrees diſtinctly marked for the natural Growth of Plants of every Climate, from the Equinoctial Line to the fifty-ſecond Degree of Latitude.

Theſe *Thermometers* are marked with the Names, and alſo the principal Places, with their Degrees of Latitude and *Summer* Heat, whether they lie North or South of the Equinoctial Line; and alſo the different Times of the *Spring* in ſeveral Countries.

By this Means every Gardener may know when it is proper to apply his Heat in its full Force, and what Degree of Heat ought to be uſed for the Welfare of any Plant from any Part of the World.

Mr. *Patrick* has fixed his *Thermometer* to a Scale of ninety Degrees, which are numbered from the Top downward, and alſo a moveable Index fitted to it.

The Deſign of this is to ſhew how the Heat or Cold is changed, from the Time it was laſt looked upon, according to the different Degrees of Heat and Cold in all Latitudes; as by the Trial of two *Thermometers* that have been regulated abroad, the one by Dr. *Halley* in his late Southern Voyage, and the other by Captain *Johnſon* in his Voyage to *Greenland*. The firſt has a Degree of Heat under the Equinoctial Line, and the other a Degree of Cold in 88 Degrees North Latitude.

Theſe Inſtruments, the *Barometer*, *Hygrometer* and *Thermometer* or *Thermoſcope*, diſcover the Alterations of the *Air* as to *Wet* or *Dry*, eſpecially if it be accompanied with an *Hygrometer*; and the *Thermometer* ſhews the Condition of the *Air* as to *Heat* or *Cold*.

The Method preſcribed to be uſed in keeping the Accounts or Obſervations made on the Alterations of theſe Inſtruments, is that which was uſed by the honourable *Samuel Molyneux*, Eſq;

1. There muſt be a Book for the Remarks in all the twelve Months of the Year, which are to be made ſix times every Day. At theſe Times you muſt obſerve:

1. How the Quickſilver riſes or falls in the *Barometer*.
2. What is the Alteration of the *Hygrometer*.
3. How the Spirits in the *Thermometer* riſe or fall.
4. From what Point of the Compaſs the Wind blows; and alſo with what Strength, according to the neareſt Gueſs that can be made.
5. Whether it rains, ſnows, hails, *&c.* and in what Quantity.

Every Leaf of the Book is to be divided into ſeveral Columns; the firſt for the Day of the Month and the Week, the ſecond for the Number of Inches and Parts of an Inch in the Tube of the *Barometer* where the Quickſilver ſtands at the Time when the Obſervation is made.

The *ſecond* is to be for marking the Degrees which the Index of the *Hygrometer* points to at the ſame Time.

The *third* is for ſhewing the Number of Inches and Parts of an Inch where the Spirits ſtand in the *Thermometer* at the Time when the Obſervation is made.

The *fourth* is for marking from what Point the Winds blow, and their Strength.

The *fifth* is for noting the Quantity of Rain, *&c.* that falls, and what Diſpoſition the Clouds and Air have.

Take, for Example, the following Account of the 2d of *June*, 1721, which Table the Reader will find inſerted in the following Page.

According to this Method, a Weather-book may be kept of the Country a Perſon reſides in, by comparing the Motions of the Quickſilver and Spirit with the Weather, at ſuch Times as the Obſervations are made, a little Practice will enable a Perſon to give a good Judgment before-hand what Weather will happen.

For the greater Accuracy, many have the Names of the principal *Exoticks* written upon their *Thermometers*, over-againſt the ſeveral Degrees which are found by Experience to be propereſt for them; and the moſt curious Gardeners about *London* have agreed to make uſe of *Thermometers* of this Sort: Which are made by Mr. *John Fowler* in *Sweetin's-alley*, near the *Royal Exchange*; which have the Names of the following Plants oppoſite to their reſpective moſt kindly Degrees of Heat.

The TABLE.

Friday, June 2. 1721.	Barometer. Inch.	Barometer. Par.	*Hygrometer, with its Diviſion and Parts.*	*Thermometer*	*Wind.*	*Weather.*
Morning at 9.	29	98	240	30	Eaſt, briſk Gale.	Cloudy.
Noon.	29	98	260 20	28	Eaſt, briſk Gale, or *ditto.*	
Afternoon at 3.	29	98	280 20	28	*Ditto.*	*Ditto.*
Afternoon at 6.	29	98	300 20	27	*Ditto.*	*Ditto.*
Evening at 9.	29	98	315 15	28	*Ditto.*	*Ditto.*
Midnight.	29	98	320 5	28	*Ditto.*	*Ditto.*

Which, ſays the Reverend Mr. *Hales* in his excellent Treatiſe of *Vegetable Staticks*, in my *Thermometers* anſwer nearly to the following Degrees of Heat above the freezing Point, *viz. Melon-thiſtle* 31. *Ananas* 29. *Piamento* 26. *Euphorbium* 24. *Cereus* 21 ½. *Aloe* 19. *Indian Fig* 16 ½. *Ficoides* 14. *Oranges* 12. *Myrtles* 9.

Mr. *Boyle*, by placing a *Thermometer* in a Cave, which was cut ſtrait into the Bottom of a Cliff, fronting the Sea, to the Depth of 130 Feet, found the Spirit ſtood both in *Winter* and *Summer* at a ſmall Diviſion above Temperate; the Cave had 80 Feet Depth of Earth above it.

I, ſays Mr. *Hales*, marked my ſix *Thermometers* numerically, 1, 2, 3, 4, 5, 6. The *Thermometer* Number 1, which was the ſhorteſt, I placed with a South Aſpect in the open Air; the Ball of Number 2 I ſet two Inches under Ground; that of Number 3 four Inches, Number 4 eight Inches, Number 5 ſixteen Inches, and Number 6 twenty-four Inches: And that the Heat of the Earth at thoſe ſeveral Depths may the more accurately be known, it is proper to place near each *Thermometer* a Glaſs Tube, ſealed at both Ends, of the ſame Length with the Stems of the ſeveral *Thermometers*, and with tinged Spirit of Wine in them to the ſame Height as in each correſponding *Thermometer*; the Scale of Degrees of each *Thermometer* being marked on a ſliding Ruler, with an Index at the Back of it, pointing to the correſponding Tube.

When at any Time an Obſervation is to be made, by moving the Index to point to the Top of the Spirit in that Tube, an accurate Allowance is hereby made for very different Degrees of Heat and Cold in the Stems of the *Thermometers* at all Depths; by which Means the Scale of Degrees will ſhew truly the Degrees of Heat in the Balls of the *Thermometers*, and conſequently the reſpective Heats of the Earth, at the ſeveral Depths where they are placed.

The Stems of theſe *Thermometers* which were above the Ground, were fenced from Weather and Injuries, by ſquare Wooden Tubes. The Ground they were placed in, was a Brick Earth in the Middle of my Garden.

July the 30th, he began to keep a Regiſter of their Riſe and Fall: During the following Month of *Auguſt* he obſerved, that when the Spirit in the *Thermometer*, Number 1, (which was expoſed to the Sun) was about Noon riſen to 48 Degrees; then the ſecond *Thermometer* was 45, the fifth 33, and the ſixth 31; the third and fourth at intermediate Degrees: The fifth and ſixth *Thermometer* kept nearly the ſame Degree of Heat, both Night and Day, till towards the latter End of the Month; when, as the Days grew ſhorter and cooler, and the Nights longer and cooler, they then fell to 25 and 27 Degrees.

Now ſo conſiderable a Heat of the Sun at two Feet Depth under the Earth's Surface, muſt needs have a ſtrong Influence in raiſing the Moiſture at that and greater Depths, whereby a very great and continual Reek muſt always be aſcending during the warm *Summer* Seaſon, by Night as well as by Day; for the Heat at two Feet deep is nearly the ſame Night and Day; the Impulſe of the Sun-beams giving the Moiſture of the Earth a briſk undulating Motion, which watery Particles, when ſeparated and rarefied by Heat, do aſcend in the Form of a Vapour; and the Vigour of the warm and confined Vapour (ſuch as is that which is one, two, or three Feet deep in the Earth) muſt be very conſiderable, ſo as to penetrate the Roots with ſome Vigour; as we may reaſonably ſuppoſe from the vaſt Force of confined Vapour in *Æolipiles*, in the Digeſter of Bones, and the Engine to raiſe Water by Fire.

If Plants were not in this Manner ſupplied with Moiſture, it were impoſſible for them to ſubſiſt under the ſcorching Heats within the Tropicks, where they have no Rain for many Months together: For though the Dews are much greater there than in theſe more Northern Climates; yet doubtleſs, where the Heat ſo much exceeds ours, the whole Quantity evaporated in a Day there, does as far exceed the Quantity that falls by Night in Dew, as the Quantity evaporated here in a *Summer*'s Day is found to exceed the Quantity of Dew which falls in the Night.

But the Dew which falls in a hot *Summer* Seaſon cannot poſſibly be of any Benefit to the Roots of Trees, becauſe it is remanded back from the Earth by the following Day's Heat, before ſo ſmall a Quantity of Moiſture can have ſoaked to any conſiderable Depth.

The great Benefit therefore of Dew in hot Weather, muſt be by being plentifully imbibed into Vegetables, thereby not only refreſhing them for the preſent, but alſo furniſhing them with a freſh Supply of Moiſture, towards the great Expences of the ſucceeding Day.

It is therefore probable, that the Roots of Trees and Plants are thus, by Means of the Sun's Warmth, conſtantly irrigated with freſh Supplies of Moiſture; which, by the ſame Means, inſinuates itſelf with ſome Vigour into the Roots: For if the Moiſture of the Earth were not thus actuated, the Roots muſt then receive all their Nouriſhment meerly by imbibing the next adjoining Moiſture from the Earth; and conſequently the Shell of the Earth, next the Surface of the Roots, would always be conſiderably drier, the nearer it is to the Root, which I have not obſerved to be ſo.

And by Experiment eighteen and nineteen, the Roots would be very hard put to it to imbibe ſufficient Moiſture in dry *Summer* Weather, if it were not thus conveyed to them by the penetrating Warmth of the Sun: Whence, by the ſame genial Heat, in Conjunction with the Attraction of the Capillary Sap-veſſels, it is carried up through the Bodies and Branches of Vegetables, and thence paſſing into the Leaves, it is there moſt vigorouſly acted upon in thoſe thin Plates, and put into an undulating Motion by the Sun's Warmth, whereby it is moſt plentifully thrown off and perſpired thro' their Surface; whence, as ſoon as it is diſentangled, it mounts with great Rapidity in the free Air.

But when, towards the latter End of *October*, the Vigour of the Sun's Influence is ſo much abated, that the firſt *Thermometer* was fallen to three Degrees above the freezing Point, the ſecond to ten Degrees, the fifth to fourteen Degrees, and the ſixth to ſixteen Degrees; then the briſk Undulations of the Moiſture of the Earth, and alſo of the aſcending Sap much abating, the Leaves faded and fell off.

The greateſt Degree of Cold, in the following *Winter*, was in the firſt twelve Days of *November*; during which Time the Spirit in the firſt *Thermometer* was fallen four Degrees below the freezing Point, the deepeſt *Thermometer* ten Degrees: The Ice on Ponds was an Inch thick: The Sun's greateſt Warmth, at the *Winter Solſtice*, in a very ſerene, calm, froſty Day, was againſt a South Aſpect of a Wall nineteen Degrees, and in a free open Air, but eleven Degrees above the freezing Point.

From the 10th of *January* to the 29th of *March* was a very dry Seaſon; when the green Wheat was generally the fineſt that was ever remembered: But from the 29th of *March*,

March, 1725, to the 29th of *September* following, it rained more or leſs almoſt every Day, except ten or twelve Days about the Beginning of *July*; and that whole Seaſon continued ſo very cool, that the Spirit in the firſt *Thermometer* roſe but to twenty four Degrees, except now and then a ſhort Interval of Sun-ſhine; the ſecond only to twenty Degrees, the fifth and ſixth to twenty-four and twenty-three Degrees, with very little Variation: So that during this whole *Summer*, thoſe Parts of Roots which were two Feet under Ground, had three or four Degrees more Warmth than thoſe which were but two Inches under Ground: And at a Medium, the general Degree of Heat thro this whole *Summer*, both above and under Ground, was not greater than the Heat of the Middle of the preceding *September*.

THLASPI, [Θλάσπί, ſo called of ϑλάω, to *compreſs* or *ſqueeze together*, becauſe the Huſk of it is very much compreſſed] Mithridate-muſtard.

The *Characters* are;

The Flower conſiſts of four Leaves, which are placed in form of a Croſs; out of whoſe Cup riſes the Pointal, which afterward becomes a ſmooth roundiſh Fruit, having commonly a leafy Border, and ſlit on the upper Side, divided into two Cells by an intermediate Partition placed obliquely with reſpect to the Valves, and furniſhed with ſmooth roundiſh Seeds: To theſe Marks muſt be added, the undivided Leaves which diſtinguiſh it from Creſſes.

The *Species* are;

1. Thlaspi *arvenſe ſiliquis latis. C. B. P.* Field Mithridate-muſtard, with broad Pods.
2. Thlaspi *montanum, ſempervirens. C. B. P.* Mountain ever-green Mithridate-muſtard.
3. Thlaspi *Creticum quibuſdam, flore rubente & albo. J. B.* Candy Mithridate-muſtard, with a reddiſh and white Flower, *commonly called* Candy Tuft.
4. Thlaspi *umbellatum arvenſe amarum. J. B.* The bitter Field umbellated Mithridate-muſtard.
5. Thlaspi *Roſa de Hierico dictum. Mor. Hiſt.* Mithridate-muſtard, *called* the Roſe of Jericho.
6. Thlaspi *arvenſe, vaccariæ incano folio. C. B. P.* Common Mithridate-muſtard.
7. Thlaspi *vaccariæ incano folio, minus. C. B. P.* Small hoary-leafed Mithridate-muſtard.
8. Thlaspi *capſulis hirſutis. J. B.* Mithridate-muſtard, with hairy Pods.
9. Thlaspi *capſula cordata, peregrinum. J. B.* Foreign Mithridate-muſtard, with a heart-ſhaped Pod.
10. Thlaspi *allium redolens. Mor. Hiſt.* Mithridate-muſtard, ſmelling like Garlick.
11. Thlaspi *arvenſe perfoliatum majus. C. B. P.* Greater Field Mithridate-muſtard, with thorough-wax Leaves.
12. Thlaspi *perfoliatum minus. C. B. P.* Smaller thorough-wax-leafed Mithridate-muſtard.
13. Thlaspi *parvum ſaxatile, flore rubente. C. B. P.* Small Rock Mithridate-muſtard, with a reddiſh Flower.
14. Thlaspi *Alpinum, folio rotundiore carnoſo, flore purpuraſcente. Inſt. R. H.* Mithridate-muſtard of the Alps, with a rounder fleſhy Leaf, and a purpliſh Flower.
15. Thlaspi *minimum Luſitanicum, cochleariæ folio. Inſt. R. H.* The leaſt Portugal Mithridate-muſtard, with a Scurvy-graſs Leaf.
16. Thlaspi *Alpinum minimum, foliis craſſis & anguſtis. Inſt. R. H.* The leaſt Mithridate-muſtard of the Alps, with narrow fleſhy Leaves.
17. Thlaspi *Luſitanicum umbellatum, gramineo folio, flore purpuraſcente & albo. Inſt. R. H.* Portugal Mithridate-muſtard, with a Graſs Leaf, and purpliſh or white Flowers, growing in an Umbel.
18. Thlaspi *Orientale ſaxatile, flore rubente, foliis polygalæ, petalis florum æqualibus. Tourn. Cor.* Eaſtern Rock Mithridate-muſtard, with Milkwort Leaves, and reddiſh Flowers, whoſe Petals are equal.
19. Thlaspi *Orientale tenuifolium canneſcens, flore albo. Tourn. Cor.* Eaſtern Mithridate-muſtard, with narrow Leaves which are hoary, and a white Flower.
20. Thlaspi *Orientale glabrum, ſamoli foliis. Tourn. Cor.* Smooth Eaſtern Mithridate-muſtard, with ſamolus Leaves.
21. Thlaspi *Orientale, folio cynocrambes flore minimo. Tourn. Cor.* Eaſtern Mithridate-muſtard, with a Dogs-mercury Leaf, and a very ſmall Flower.
22. Thlaspi *Virginianum, foliis Iberidis amplioribus & ſerratis. Inſt. R. H.* Virginia Mithridate-muſtard, with Leaves like the Sciatica-creſs, which are broader, and ſaw'd on their Edges.
23. Thlaspi *montanum ſempervirens. C. B. P.* Ever-green Mountain Mithridate-muſtard.
24. Thlaspi *Orientale fruticoſum, ſcammonii Monſpelienſis folio. Tourn. Cor.* Shrubby Eaſtern Mithridate-muſtard, with the Leaf of Montpelier Scammony.
25. Thlaspi *foliis globulariæ. J. B.* Treacle-muſtard, with Leaves like Globulariæ.

The firſt Sort is ſometimes found wild in *England*, but not near *London*. This is the Sort of which the College of Phyſicians have ordered the Seeds to be uſed in ſome of the grand Medicines of the Shops; tho' the Seeds of ſeveral other Plants are commonly ſubſtituted inſtead of it, becauſe the Seeds of this Sort are not very common in *London*; but the Plants might be eaſily cultivated in ſuch Plenty, as to furniſh the Town with the right Sort, the Plant being extreme hardy, and requires no other Culture but to ſow the Seeds in *February*, upon an open Spot of Ground; and when the Plants are come up, they muſt be conſtantly cleared from Weeds: In *June* they will flower, and the Seeds will ripen ſoon after; when the Plants do always periſh being annual.

The ſecond, third, fourth and fifth Sorts are commonly cultivated in Flower-gardens, where formerly they were ſown for *Summer* Edgings to Borders; but as they are apt to grow too rank for that Purpoſe, ſo the better Way is to ſow the Seeds in ſmall Patches in the Middle of the Borders between the taller Flowers; and when the Plants are come up, they ſhould be thinned, and kept clear from Weeds, which will cauſe them to flower much ſtronger than if they are drawn up weak.

Theſe Plants do flower in *June* and *July*, and their Seeds do ripen ſoon after; but in order to have a Succeſſion of theſe and other ſmall annual Flowers, many Perſons do ſow them at two or three different Seaſons, *viz.* in *March*, *April* and *May*; by which Means they continue them until the Froſt comes in *Autumn*; but thoſe Seeds which are ſown late in the *Spring* ſhould be carefully watered in dry Weather, otherwiſe they ſeldom grow.

The red and white Candy Tufts do vary ſo as not to be kept ſeparate; the Seeds of the red producing ſome white Flowers, and thoſe of the white ſome with red ones; but of late, the *bitter umbellated Sort* has been cultivated in Gardens, and the Seeds ſold in the Shops, by the Name of *White Candy Tuft*, tho' in Reality it is a different Plant: However, as this Sort produces beautiful white Flowers, it ſhould have a Place in the Borders of the Flower-garden, for the ſake of Variety.

The *Roſe of Jericho* is a Plant of no great Beauty or Uſe, ſo is ſeldom cultivated, except in Botanick Gardens. This requires the ſame Culture as the former Sorts, and is alſo an annual Plant.

The ſixth Sort grows plentifully wild amongſt the Corn, and by the Sides of Hedges, in moſt Parts of *England*. The Seeds of this Sort are generally ſold by the Druggiſts in *London* for the true *Mithridate-muſtard*; but the firſt Sort is what the College of Phyſicians have directed to be uſed in the *Theriaca*.

The ſeventh, eighth, ninth and twentyfifth Sorts do alſo grow wild in ſome Parts of *Great Britain*, but are not ſo common as the former Sort, eſpecially the twentyfifth; which is found in the mountainous Paſtures in *Yorkſhire*, and ſome other Places in the North; but is not to be met with in the South, unleſs in ſome curious Botanick Gardens, where it is preſerved for the ſake of Variety.

The ſixth, and ſixteen following Sorts, are annual Plants, which if permitted to ſhed their Seeds on the Ground, will ſucceed much better than when ſown by Hand, eſpecially if they are not ſown in *Autumn*; for when the Seeds are ſown in the *Spring*, if the Seaſon ſhould prove dry, they ſeldom grow; and if they do come up, the Plants will be very ſmall, and produce little Seed; whereas thoſe Plants which come up in *Autumn* will abide the *Winter*'s Cold very well, and the following *Spring* will get Strength before the hot Weather comes in; ſo will flower, and produce Plenty of Seeds.

Some of theſe Sorts do produce pretty Flowers growing in Cluſters, which renders them worthy of a Place in large Gardens, where there is Room for Variety, eſpecially as they require very little Trouble to cultivate them. For none of theſe Sorts ſhould be tranſplanted, but ſown where they are deſigned to remain; and if they are kept clear from Weeds, it is all the Culture they require. Many of theſe Plants will grow on the Top of old Walls, or other Buildings; where they will ſhed their Seeds, and maintain themſelves without Care; and growing very low and ſtunted will produce a great Number of Flowers; ſo will make a pretty Appearance in the *Spring*, when they are in flower.

The twentythird Sort is an abiding Plant, which continues always green, and flowers a long time. The Flowers of this Kind grow in Umbels at the Extremity of the Shoots, which reſemble thoſe of the *Candy-tuſt* Tree, but are ſmaller. The Leaves of this Sort are narrow and pointed; and the whole Plant ſeldom riſes above ſix Inches high. This Sort ſeldom produces good Seeds in *England*, but may be propagated by Cuttings, which ſhould be planted in a ſhady Border, during any of the *Summer* Months; and in dry Weather they muſt be frequently watered. When theſe are well rooted, they may be tranſplanted where they are deſigned to remain, which ſhould be on a dry rubbiſhy Border, where they will thrive and flower much better than in a rich Soil. This Plant is hardy enough to endure the Cold of our ordinary Winters very well in the open Air; but in very ſevere Froſts they are ſometimes deſtroyed; for which Reaſon it will be proper to have a few Plants in Pots, which may be ſheltered in *Winter*, in order to preſerve the Kind.

The twentyfourth Sort was diſcovered by Dr. *Tournefort* in the *Levant*; this Plant grows to the Height of two Feet or more, and becomes ſhrubby. The Flowers of this Kind are ſmall, ſo do not make a very good Appearance; but the Plant is preſerved by ſome curious Perſons for the ſake of Variety. This Sort may be propagated by Cuttings during any of the *Summer* Months, in like manner as the laſt mentioned, but is ſomewhat tenderer; ſo theſe, when they are rooted, ſhould be planted in Pots, and ſheltered in *Winter*, in the ſame Manner as hath been directed for the *Candy-tuſt* Tree.

THLASPIDIUM, [is ſo called of *Thlaſpi*, becauſe it ſomething reſembles this Plant.] Baſtard Mithridate-muſtard.

The *Characters* are;

The Flower conſiſts of four Leaves, which are placed in form of a Croſs, out of whoſe Cup riſes the Pointal, which afterwards becomes a double ſmooth Fruit, compoſed of two Parts, that are ſeparated by an intermediate Partition; each of which ſwells with a red Seed, which is generally flat and oblong.

The *Species* are;

1. Thlaspidium *fruticoſum, leucoii folio, ſemper-florens. Tourn.* Shrubby Thlaſpidium, with a Wall-flower Leaf, and always flowering, *commonly call'd* The Candy Tufttree.
2. Thlaspidium *fruticoſum, leucoii folio variegato, ſemper-florens. Tourn.* The ſtriped Candy Tuft-tree, *vulgo.*
3. Thlaspidium *Monſpelienſe, hieracii folio hirſuto. Inſt. R. H.* Montpelier Thlaſpidium, with a hairy hawk-week Leaf.
4. Thlaspidium *hirſutum, calyce floris auriculato. Inſt. R. H.* Hairy Thlaſpidium, with an eared Flower-cup.
5. Thlaspidium *annuum, flore pallidè luteo. Inſt. R. H.* Annual Thlaſpidium, with a pale yellow Flower.
6. Thlaspidium *raphani folio. Inſt. R. H.* Radiſh-leav'd Thlaſpidium.
7. Thlaspidium *anchuſæ folio. Inſt. H. R.* Alkanet-leav'd Thlaſpidium.
8. Thlaspidium *Apulum ſpicatum. Inſt. R. H.* Spiked Thlaſpidium of Apulia.
9. Thlaspidium *montanum anguſtifolium glabrum. Inſt. R. H.* Smooth narrow-leav'd mountain Thlaſpidium.
10. Thlaspidium *Alpinum pumilum aſperum. Inſt. R.H.* Low rough Thlaſpidium of the Alps.
11. Thlaspidium *Apulum incanum, floribus ex albo purpuraſcentibus. Inſt. R. H.* Hoary Thlaſpidium of Apulia, with white purpliſh Flowers.
12. Thlaspidium *Hiſpanicum, ampliore flore, folio craſſo dentato. Hort. Elth.* Spaniſh Thlaſpidium, with a large Flower, and a thick indented Leaf.

The firſt of theſe Plants here mentioned is pretty common in the Gardens near *London*, where it is preſerved in Greenhouſes with other exotick Plants, for the Beauty of its Flowers, which are commonly continued throughout the whole Year, making a very beautiful Figure in the Greenhouſe, at ſuch Seaſons when few other Plants are in Flower.

This Plant may be propagated by planting either Cuttings or Slips during any of the *Summer* Months, in Pots filled with freſh light Earth, and placed under a Frame, obſerving to water and ſhade them until they have taken Root, after which they may be expoſed to the open Air, and when they have gotten ſtrong Roots, they may be each tranſplanted into a ſeparate Pot, filled with light freſh Earth, and may be placed amongſt other hardy exotick Plants in the open Air in *Summer*; but in *Winter* they muſt be ſcreened from ſevere Froſt, tho' in mild Weather they ſhould have as much free Air as poſſible.

But altho' theſe Plants are generally preſerved in Pots, and placed in a Green-houſe in *Winter*, yet after they have acquired Strength, they may be planted in warm dry Borders; where, if the Soil be freſh, and not too rich, they will endure the Cold of our ordinary *Winters* very well without any Covering: And the Plants thus treated will flower much better than thoſe kept in Pots.

The ſtriped Sort is propagated as the plain, and muſt be treated in the ſame Manner; but being ſomewhat tenderer, muſt be conſtantly ſheltered in *Winter*, otherwiſe it will be deſtroyed in a ſmall Froſt.

The third Sort here mentioned, is an abiding Plant of humble Growth, ſeldom riſing above ſix Inches high. This is very common in the South of *France*, *Italy*, *Sicily*, and *Spain*, where it uſually flowers in *May* and *June*; and the Seeds are ripe in *July*. In *England* this Plant is preſerved by ſome curious Perſons, for the ſake of Variety; tho' there is no great Beauty in its Flowers. They are hardy enough to endure the Cold of our *Winters* in the open Air, provided they are ſown on a dry rubbiſhy Soil; for if they are ſown on a rich moiſt Soil, they grow ſo rank in *Summer*, that the firſt Froſt in *Autumn* uſually deſtroys them. Theſe Plants do not bear tranſplanting very well; ſo they ſhould be ſown where they are deſigned to remain, and thin them where they come up too cloſe, leaving the Plants about ſix or eight Inches aſunder; and then, if they are kept clear from Weeds, it is the only Culture they require. Some of theſe Plants will flower the ſame Seaſon they are ſown; but unleſs the *Autumn* proves dry and warm, they ſeldom produce good Seeds; therefore the ſureſt Method is to ſow the Seeds in *Autumn*, when the Plants will come up, and abide the *Winter*; ſo will flower early the following *Summer*, and the Seeds will come to Perfection.

The fourth Sort will ſometimes live two Years, if it grows on a lean dry Soil; but if this is ſown in *Autumn*, as the former Sort, it will flower, and produce good Seeds.

The fifth, ſixth, ſeventh, eighth, ninth, tenth, and eleventh Sorts, are all of them annual Plants; theſe ſhould be alſo ſown about the Middle of *Auguſt*, on a dry poor Soil in a warm Situation, where the Plants will abide the Cold of our *Winters* very well, and will flower early the following *Spring*, ſo that good Seeds may be obtain'd from them. Theſe Seeds, if they are permitted to ſcatter, will come up and thrive without any farther Care, but to keep them from being over-run with Weeds; therefore may be allowed a Place on dry rubbiſhy Borders, or on old Walls or Ruins, where they will flower, and make an agreeable Variety.

The twelfth Sort produces large fair Flowers, which continue a long time in Beauty; ſo is worthy of a Place in every good Garden. This Sort is at preſent very rare in the *Engliſh* Gardens; but as it may be eaſily propagated by Cuttings, ſo it may be treated in the ſame manner as the *Candy-tuſt-tree*; with which Management theſe Plants will thrive and flower extremely well.

THISTLE: *vide* Carduus.

THORN-APPLE: *vide* Stramonium.

THORN, the Glaſtenbury: *vide* Meſpilus.

THUNDER, is defined by ſome to be a Noiſe in the loweſt Region of the Air, excited by a ſudden kindling of ſulphureous Exhalations.

Some alſo account for it, by ſuppoſing two Clouds impending over one another; the upper and rarer whereof becoming condenſed by a freſh Acceſſion of the Air, raiſed thither by Warmth from the lower Parts of the Atmoſphere, or driven upon it by the Wind, immediately falls forcibly down upon the lower and denſer Cloud; by which Fall the Air interpoſed between the two being compreſs'd, that next the Extremities of the two Clouds is ſqueez'd out, and leaves Room for the Extremity of the upper Cloud to cloſe tight upon the under: thus a great Quantity of Air is incloſed, which eſcaping thro' ſome winding irregular Vent or Paſſage, it occaſions the Noiſe we call *Thunder*.

But this only reaches to the *Phænomena* of *Thunder* heard without *Lightning*; and, in Effect, we have now a better Solution: that *Thunder* is not occaſion'd by the falling of the Clouds, but by the kindling of ſulphureous Exhalations in the ſame manner as the Noiſe of *Aurum Fulminans*.

Sir *Iſaac Newton* ſays, there are ſulphureous Exhalations always aſcending into the Air, when the Earth is dry; there they ferment with the nitrous Acids, and ſometimes taking Fire, generate into *Thunder*, *Lightnings*, &c.

That beſides the Vapours raiſed from Water, *&c.* there are alſo Exhalations carried off from *Sulphur*, *Bitumen*, *volatile*

latile Salts, &c. is paſt all Doubt: the vaſt Quantity of ſulphureous and bituminous Matter all over the Surface of the Earth, and the volatile Salts of Plants and Animals afford ſuch an ample Stock thereof, that it is no Wonder the Air ſhould be fill'd with ſuch Particles, raiſed higher or lower, according to their greater or leſs Degree of Subtilty and Activity, and more copiouſly ſpread in this or that Quarter, according to the Direction of the Winds, &c.

The Atmoſphere about the Earth abounds with nitrous Particles of a ſpirituous Nature, which are every-where carried along with it; beſides which ſort of Particles, there are others raiſed up into the Air, which may be ſomewhat of the Nature of ſulphureous, nitrous, and other combuſtible Bodies: as we ſee Spirit of Wine, Spirit of Turpentine, Camphire, and almoſt all other combuſtible Bodies will by Heat be rarefied into the Form of Air or Smoke, and be raiſed up into the Air.

All which, if they have a ſufficient Degree of Heat will catch Fire, or be turn'd into Flame by the nitrous Parts of the Air, as thouſands of Experiments might be brought to prove.

There are alſo other Sorts of theſe ſulphureous Steams which ariſe from the ſubterraneous and mineral Bodies, which only by their coming to mix with the Nitre of the Air, tho' they have no ſenſible Heat in them, will ſo ferment and act one upon another as to produce an actual Flame, which is a thing that has often been found in Mines, and more eſpecially if any Part of them be kindled; then the whole Train, which is mingled with the contiguous Air, will immediately take Fire like a Train of Gunpowder, and then run from one End of thoſe Vapours to the other, be they ever ſo long; as I could prove by a multitude of Relaons from Coal Mines, and ſeveral other Mines.

The Aſcenſion of which Vapours is ſo ſudden, and with ſuch Violence and Swiftneſs runs from one End to the other, as often to kill the Miners, blow up their Props, Turns, Stays, Houſes, &c. and produces as prodigious Effects, as if a vaſt Quantity of Gun-powder had been fired in the Mine.

Now *Lightning* in the Air ſeems to be much of the ſame Nature; for the Air is continually furniſh'd with ſpirituous, nitrous Parts, and the *Summer* Heat, whenever extraordinary, raiſes up out of the Earth (and to this the ſubterranean Heat alſo is continually concurring) a great Quantity of ſulphureous Vapours, which are of ſuch a Nature, as that meeting with the Nitre of the Air, they work upon each other, and thereby begin a farther Degree of Heat, which gradually increaſes, till at laſt it arrives at a certain Pitch, and then they fall upon, and work upon one another, producing an actual Fire and Flame, which with wonderful Swiftneſs fires the whole Train, and ſo produces a Flaſh and Noiſe. Thus Dr. *Hook*.

Dr. *Wallis*, in *Philoſ. Tranſact.* N°. 231. ſays, that *Thunder* and *Lightning* are ſo very like the Effects of fired Gunpowder, that we may reaſonably judge they proceed from the like Cauſes.

Now the principal Ingredients in Gunpowder are Nitre and Sulphur, (the Admiſſion of Charcoal being chiefly to keep their Parts ſeparate, for the better kindling of it) ſo that if we ſuppoſe in the Air a convenient Mixture of nitrous and ſulphureous Vapours, and thoſe by Accident to take Fire, ſuch Exploſion may well follow with Noiſe and Light, as in the firing of Gunpowder; and being once kindled, it will run from Place to Place, as the Vapour leads it, like as in a Train of Gunpowder, with the like Effects.

This Exploſion, if high in the Air, and far from us, will do no Miſchief, or not conſiderable, like a Parcel of Gunpowder fired in the open Air, where nothing is near enough to be hurt by it: but if the Exploſion be near to us, or amongſt us, it may kill Men or Cattle, tear Trees, fire Gunpowder, break Houſes, or the like, which Gunpowder would do in like Circumſtances.

This *Nearneſs* and *Farneſs* may be eſtimated by the Diſtance of the Time between ſeeing the Flaſh of *Lightning*, and hearing the Clap of *Thunder*; for tho' in their Generation they be *ſimultaneous*, yet Light moving faſter than Sound, they come to us ſucceſſively.

I have obſerv'd, that commonly the Noiſe is about ſeven or eight Seconds after the Flaſh; but ſometimes it is much ſooner in a Second or two, or leſs than that, juſt after the Flaſh; and then the Exploſion muſt needs be very near us, and even amongſt us: and, in ſuch Caſes, I have more than once preſaged the Expectation of Miſchief, and it hath proved accordingly.

Now that there is in *Lightning* a ſulphureous Vapour, is manifeſt from the ſulphureous Smell that attends it, and the ſultry Heat in the Air, which is commonly a Fore-runner of *Lightning*.

And that there is a nitrous Vapour in it, we may reaſonably judge, becauſe we do not know of any Body ſo liable to a ſudden and violent Exploſion.

As to the kindling of thoſe Materials, in order to ſuch an Exploſion, I am told, that a Mixture of Sulphur and Filings of Steel, with the Admiſſion of a little Water, will not only produce a great Efferveſcence, but will of itſelf break forth into an actual Fire: I ſay, a *little Water*, becauſe too much will hinder the Operation, or quench the Fire.

And this I take to be the Cauſe of the *Bath-waters*, and other hot Springs, where Steel and Sulphur cauſe a great Efferveſcence, but no Flame; ſo that there wants only ſome *Chalybeate* or *vitriolick Vapour* (or ſomewhat equivalent) to produce the whole Effect, (there being no Want of aqueous Matter in the Clouds) and there is no doubt, but that amongſt the various *Effluvia* from the Earth, there may be copious Supplies of Matter for ſuch Mixtures.

The ſame Account may be alſo given of *Ætna*, and other burning Mountains, where the Mixture of Iron and Sulphur may give a Flame, which is often attended with prodigious Exploſions and Earthquakes, from great Quantities of Nitre, as in ſpringing a Mine.

M. *Le Clerc* defines *Thunder to be a rumbling Noiſe in the higheſt Region of the Air, occaſioned by the ſudden Inflammation of Exhalations.*

This he explains and accounts for to the Purpoſes following:

Beſides thoſe Vapours that are raiſed by the Heat of the Sun, out of the Water and moiſt Places, there are alſo a world of Particles, which are carried off from Sulphur, Bitumen, volatile Salts, and other Bodies of the like Nature; theſe Particles fly about in the Air, either higher or lower, according to the various Degrees of their Levity and Gravity; and theſe are thoſe which are by Naturaliſts commonly call'd Exhalations.

Since it is evident, that there is a vaſt Quantity of ſulphureous and bituminous Matter all over the Surface of the Earth, and alſo that both Plants and Animals abound with volatile Salts, there is no Cauſe that we ſhould wonder why the Air is fill'd with ſuch Particles by the Heat of the Sun.

Nor is it poſſible but that they ſhould be driven about all over the Air; but it is not to be doubted, but that they ariſe in greateſt plenty from dry ſun-burnt Places, and hang thereabout; and hence it is eaſy to account for all thoſe Meteors, which are inflamed in the Air.

In all aerial Fires there are three Things obſervable:

1. That they are lighted without any human Means, and by ſome inviſible Way.
2. That they run about the Air in various Figures.
3. That ſome of them continue longer than others do; but yet they all vaniſh in a ſhort time.

In order to make a Flame or Spark appear, there is nothing more neceſſary, than that there ſhould be ſome Particles ſo whirl'd about in the Air, as to caſt aſide all the groſſer Matter, and play about in the moſt ſubtil Part of the Air.

Now there are ſome Matters which are apter to be put in Motion than others; ſuch as the Parts of Sulphur, Bitumen, Nitre, &c.

Therefore, when a ſufficient Quantity of Matter of theſe Kinds are gotten together, it is no difficult matter for one or two of thoſe Particles to be whirl'd about by the Heat of the Air; and when they are once inflamed, to ſet Fire to all the reſt that are about them; as a Conſequence of which it is obſervable, that theſe aerial Fires are common in *Summer*, but more rare in *Winter*; and by how much the *Summer* is hotter, the more common ſuch Fires are: And this ſufficienly ſhews, that the Matter of ſuch Fires is raiſed and inflamed by the heat of the Air, and the impetuoſity of its Motion.

This may be demonſtrated by an Experiment made by the Preparation which Chymiſts call *Aurum fulminans*. Gold being diſſolved in *Aqua Regia*, and precipitated with Oil of *Tartar*, the Duſt which ſinks to the Bottom, after it has been dried gradually, and without Fire, will afterwards be fired by a moderate Heat, and will go off with a Noiſe like that of a Muſquet diſcharged.

This Experiment may alſo be made at a leſs Expence, and alſo as effectually, by mixing three Drams of Salt-petre with one Dram of Brimſtone, and a Dram and a half of Tartar, and beating them to a very fine Powder; this being done, the Powder will take Fire as readily as the *Aurum fulminans*, but will not give quite ſo great a Crack.

Now if it be conſidered, that the Particles of Nitre, Sulphur, and Tartar, which fly in Air, are much finer than thoſe of the Compoſition before-mention'd; it is eaſy to imagine,

gine, that they may be fired by a moderate Heat aloft in the Air, if they be mix'd according to the aforeſaid Proportion.

This ſort of Matter muſt be carried about the Air in various Figures, according as the Winds blow, and as it is greater or leſſer in Quantity, and according as it takes Fire.

If the Fire begins at one End, and burns gradually, it is call'd a *Lamp*; but if a long Exhalation takes Fire at once, it is call'd a *Dart:* Sometimes theſe Exhalations are hurried one way or other by the Stream of the Air, while they are in Flame; ſometimes they continue in the ſame Place, and then they are call'd *Beams*; at other times the Clouds part, and the Sky ſeems to retire, which may be cauſed by the Wind, and a Flame will flaſh out at this Opening; when this happens it is call'd a *Chaſm*.

When burning Exhalations have leſs Sulphur in them (which yields a paler Flame) than Nitre, Bitumen, or Tartar, they appear as red as Blood.

Tho' this Sort of Inflammation may appear either by Night or Day, yet they will be more plain to be ſeen in the Night, in the Abſence of the Sun, the prevalent Light of which obſcures the Sight.

Thoſe which are commonly call'd *Shooting Stars*, are but ſmall Exhalations in our Air, and therefore are not properly *Stars*.

Ignes fatui, [*Jack-in-a-Lanthorn*, *Will-in-a-Wiſp*, &c.] ſeem to conſiſt of a more greaſy Exhalation. It is evident, that oily Subſtances, tho' they are eaſily lighted, yet they are not ſpent ſo ſoon as thoſe of Sulphur and Nitre.

Hence it may be learn'd, that all ſuch inflamed Exhalations muſt neceſſarily diſappear ſoon, becauſe the ſubtil Matter of which they conſiſt is ſoon ſpent. But as the Matter of them is not all alike, ſo their Continuance is not exactly the ſame: We may obſerve that a Flame, which is raiſed out of various Materials, will either laſt longer, or be extinguiſh'd ſooner, according as they are compoſed.

Oil mix'd with Bitumen or Sulphur will flame longer than if mix'd with Nitre.

From what has been ſaid, it will be no difficult Matter to conceive how *Thunder* is produced: for the Experiment ſhews, that Flame which throws off the Air with great Violence, ſometimes occaſions a great Crack. And it being an eaſy matter for heterogeneous Particles to mix in great Quantities in the upper Region of the Air, and to be ſet on Fire by a moderate Heat; there is no need to have Recourſe to any thing elſe to explain the Cauſe of *Thunder*.

As for the Noiſe of *Thunder*, we may be ſatisfied by all Experiments, that it cannot be any otherwiſe produced, than by a ſwift and vehement Exploſion of the Air, which is forced every Way; and the Motion of it being continued to our Ears, ſtrikes the *Tympana* [*Drums*] of them, and this cauſes the Senſation we call Sound.

As to the *Noiſe of Thunder*, it is obſervable, that it ſounds as if it paſs'd thro' Arches and was broken variouſly. The Reaſon of it is, becauſe the Flame is kindled among the Clouds, that hang over one another, and the agitated Air flies between them. Thus it may be obſerved, that when a Gun is diſcharged at a good Diſtance, the Inequalities of the Ground do cauſe it to ſound to us with ſeveral repeated broken Reports.

It is alſo plain, that the Flame is the Cauſe of *Thunder*, becauſe moſt commonly the Flaſh is ſeen before the Crack is heard. There is not ſuch a Diſtance indeed between the Firing of the Exhalation and the Concuſſion of the Air, as there is between the ſeeing of the *Flaſh* and the hearing of the *Thunder*. But the Reaſon of it is, that we ſee any thing, as it were, in an Inſtant: but Sounds are convey'd to our Ears by a ſucceſſive Motion of the Air, and therefore more Time is required to hear than to ſee.

By what has been ſaid before it appears, that *Lightning* is an *inflamed Exhalation, compoſed of Sulphur and Nitre, or ſome ſuch Matter, or a Mixture of ſeveral Sorts together*. The Inflammation is ſometimes with a Noiſe, as in cloudy Weather, and ſometimes without, as in clear; which cauſes ſome Variety in it.

Sometimes it lightens without Noiſe, which is when the Exhalation conſiſts of Matter ſofter than ordinary, which is not ſo ſoon kindled. If it conſiſts only of ſulphureous Particles, which are a ſofter Sort, they are not ſo apt to fire all at once, nor give the Air ſuch a Concuſſion, as ſhall cauſe us to hear the Noiſe of it: but if there be many Particles of Nitre and Tartar mingled with the Sulphur, the former being harder, cauſe the whole Exhalation to burſt at once with ſuch Impetuoſity as to rend the Air, and to make a vaſt Noiſe.

The Noiſe of *Thunder* is more diverſify'd in cloudy Weather, becauſe the Air is variouſly reverberated from the Clouds to us; but if there are no Clouds, the Air flows thro' the open Spaces to our Ears, more freely and evenly; and it frequently *lightens* in ſuch Weather without *Thunder*, becauſe the Inflammation conſiſts only of ſulphureous Particles; and, on the contrary, it often *thunders* in cloudy Weather without any *Lightning* appearing viſibly, becauſe it is intercepted by the Clouds.

Rain generally attends *Thunder* and *Lightning*, either at the ſame Time or ſoon after; and it frequently rains faſter after a Clap of *Thunder:* So that Rain ſeems to be the Effect of *Thunder*.

As for *Thunderbolts:* When it *thunders* and *lightens*, there ſometimes falls a *Thunderbolt*. This *Thunderbolt* is a moſt rapid Flame, that darts out of the Clouds to the Ground, and ſtrikes thro' every thing that is in its Way: and it is obſerved to have the following peculiar *Phænomena*.

1. That it oftner ſtrikes upon high Places than low; as upon Mountains, Towers, Steeples, Trees, *&c.*

2. That it ſometimes burns Peoples Clothes, without hurting their Bodies.

3. That it ſometimes breaks their Bones, and at the ſame time does not hurt their Fleſh, or their Garments.

4. That it has melted or broken a Sword in a Scabbard, without hurting the Scabbard; and, on the contrary, has ſometimes burnt the Scabbard all over, and at the ſame time done no Harm to the Sword.

From theſe Conſiderations we may conclude, that a *Thunderbolt* is an Exhalation, which is kindled of a ſudden, and is copious enough to be hurried down to us by Winds.

Thunderbolts are moſt commonly darted aſlope, thro' the Air; and this may be occaſion'd by the Winds, which ſeldom or never blow downright. And it is probable, that the Flame is beaten down by the Wind, and reaches the Ground before the Matter of it is quite ſpent.

And this may be the Reaſon, that for the moſt part they ſtrike upon high Places; for as they fall obliquely thro' the Air, they often in their Way meet with Mountains, Towers, *&c.* and the Reaſon that the Force of their Flame is very different, is probably from the Difference of the Exhalations which form the *Thunderbolt*, the Bodies from which they are collected being ſulphureous, bituminous, or ſaline; and from thence it may be, that it ſometimes burns Garments at the ſame time that it paſſes over the Bodies without doing them any Harm.

Sometimes it penetrates the ſoft Fleſh harmleſsly, as to that, and yet breaks the hard Bones; as Gold and other Metals are diſſolv'd by *Aqua Regia* and *Aqua Fortis*, and in the mean time the Paper ſhall not be hurt by them. And for the ſame Reaſon it is, that a Sword may be melted in a Scabbard, and yet the Scabbard remain intire; and ſo it would be if they were both laid together in *Aqua Fortis:* becauſe the acute Parts of the *Aqua Fortis* do not operate upon ſoft Matter, the Particles of which are branched, as they do upon harder Bodies, into the Pores of which they inſinuate themſelves, and diſſolve the Contexture.

Again; *Thunderbolts* are more common in *Summer* and *Autumn* than they are in *Winter* and the *Spring*; for which, three Reaſons may be given:

1. That the Cold is ſo great in the upper Region of the Air in *Winter* and *Spring*, that it will not permit the Exhalations to take Fire.

2. That the Exhalations are fewer in thoſe Seaſons, becauſe they are kept from aſcending by the Cold; for they cannot riſe in any Quantity without a conſiderable Heat.

3. The Air is ſo fill'd with Vapours and Clouds in the *Winter* and *Spring*, that all Exhalations are dilated, and therefore are not capable of being inflamed.

Alſo ſome Places are more obnoxious to *Thunderbolts* than others, and they are ſuch as ſend forth plenty of Exhalations for that Purpoſe, and where they are not eaſily diſperſed by the Winds; and thence in hotter Countries, where the Sun exhales out of the Earth all that can be exhaled, *Thunderbolts* are more frequent than they are in Climates that are colder: So that in thoſe Places that are encompaſs'd with high Mountains, where the Wind has not Acceſs to blow ſo freely, the Exhalations are kept together, and *Thunderbolts* are more common; but in ſpacious Plains, which are, as it were, ſwept by the Winds, theſe Exhalations are ſhatter'd and blown about.

THURIFEROUS, ſignifies bearing or producing Frankincenſe.

THUYA, [ſo call'd of θύω, to *perfume with Smoke*; becauſe this Plant hath a penetrating Smell] The Arbor Vitæ, *vulgo*.

The *Characters* are;

The Leaves are ever-green, ſquamous, and compreſs'd, having ſmall oblong ſquamous Cones growing upon the Backſides, in which the Seeds are contained.

The *Species* are;

1. Thuya *Theophraſti. C. B. P.* The Arbor Vitæ, *or* Tree of Life.
2. Thuya *Theophraſti, folio variegato.* The ſtriped Arbor Vitæ, *or* Tree of Life.

The firſt Sort was formerly in greater Eſteem than at preſent in the *Engliſh* Gardens; it is commonly raiſed in the Nurſeries near *London*, where their Heads are ſheer'd into a conical Figure; but ſince that low Taſte of Gardening, in crowding vaſt Quantities of clipp'd Plants into Gardens, is juſtly exploded, theſe Trees do not meet with ſo good Reception as formerly: But notwithſtanding this, there may be ſome of them planted in Gardens to great Advantage, if they are placed in Wilderneſſes, or Clumps of ever-green Trees, where theſe ſhould be planted with other Sorts which are nearly of the ſame Growth; and in ſuch Plantations the dull, heavy green Colour of theſe Leaves, will be very uſeful in adding to the Luſtre of thoſe which are of a more lively green, and make a fine Variety.

The ſtrip'd Sort is preſerv'd by ſome who are curious in collecting ſuch Varieties; but there is little Beauty in it.

Theſe Trees may by propagated by laying down their tender Branches in the *Spring* of the Year, obſerving to ſlit them at a Joint (as is commonly practiſed for Carnations) as alſo to water them in dry Weather, and keep them conſtantly clear from Weeds: If theſe Things be duly obſerved, the Layers will be rooted by the *Spring* following, by which time they may be taken off, and tranſplanted into a Nurſery in Rows three Feet aſunder, and the Plants eighteen Inches Diſtance in the Rows; obſerving to lay a little Mulch upon the Surface of the Ground about their Roots, to prevent the Wind from drying it, and in dry Weather they ſhould be often refreſh'd with Water, until they have taken Root, after which they muſt be conſtantly kept clear from Weeds, and the Ground dug every *Spring* between the Rows, that their Roots may extend themſelves on every Side. In this Nurſery they may remain five or ſix Years, and may then be tranſplanted where they are to remain for good. The beſt Seaſon to remove theſe Trees is about the Beginning of *April*, juſt before they ſhoot.

Theſe Trees may alſo be propagated by Slips, which ſhould be planted on a moiſt Soil in *April*, and if ſhaded in very hot dry Weather, moſt of them will take Root, after which they muſt be treated as hath been directed for the Layers.

The Leaves of this Tree being bruiſed between the Fingers, emit a ſtrong Scent, ſomewhat like Ointment; and I have been inform'd, that ſome Perſons do make an Ointment thereof, which is eſteem'd excellent for freſh Wounds. The Wood of this Tree is greatly eſteem'd by the Turners, for making Bowls, Boxes, *&c.* But as the Tree is ſlow of Growth, and ſeldom arrives to any great Magnitude in this Country, (rarely growing above twenty Feet high) ſo it is not worth cultivating for its Timber.

THYMBRA.

The *Characters* are;

It hath a labiated Flower, like thoſe of Savory, Thyme, *and* Calaminth, *from which this Plant differs, in having its Flowers growing in Whorles.*

The *Species* are;

1. Thymbra *legitima. Cluſ. Hiſt.* The true Thymbra of Cluſius.
2. Thymbra *Hiſpanica, coridis folio. Inſt. R. H.* Spaniſh Thymbra, with a fair Heathpine-leaf.
3. Thymbra *Sancti Juliani, ſive Satureja vera. Lob. Icon.* Thymbra of Mount Saint Julian, or the true Savory of Lobel.

The firſt Sort riſes about two Feet high, and hath a woody Stem, and divides into many Branches, ſo as to form a ſmall Buſh; the Leaves of this Plant are ſomewhat like thoſe of *Savory*, and have a ſtrong aromatic Scent when bruiſed. This Sort grows plentifully in ſeveral Iſlands of the *Archipelago*, from whence the Seeds were ſent to ſeveral curious Perſons, who cultivate it for the ſake of Variety. This Kind may be propagated by Cuttings, which ſhould be planted in the Beginning of *April*, on a Border, where they may have only the Morning Sun; and in dry Weather they muſt be conſtantly watered, until they have taken good Root; after which time, they will require no farther Care, but to keep them clear from Weeds, till *Michaelmas*, at which time the Plants ſhould be carefully taken up and tranſplanted, ſome of them into Pots, that they may be ſhelter'd in *Winter*, and the others on a dry lean Soil in a warm Situation, where they will endure the Cold of our ordinary *Winters* very well; but in ſevere *Winters* they are frequently deſtroyed; therefore it is proper to preſerve two or three Plants in Pots under Shelter, leſt thoſe in the open Air ſhould be killed.

The ſecond Sort was diſcovered by Dr. *Tournefort* in *Caſtile*, where it grew plentifully on ſtony Ground. This a a low ever-green buſhy Plant, ſomewhat like *Thyme*; but the Leaves are broader, and the whole Plant has a more dull and ſomewhat fœtid Smell. This may be propagated by Seeds, or by Cuttings as the former Sort, and ſhould be treated in the ſame manner.

The third Sort grows in ſeveral Places in *Italy* and *Sicily*, commonly on ſtony Land, or on old Walls. This is a low Plant, ſeldom riſing above ſix Inches high, ſending forth many upright Branches from the Root, which have Spikes of ſmall Flowers, growing in Whorles on their Tops. This Sort is propagated by Seeds, which ſhould be ſown on a light lean Soil; and when the Plants are ſtrong enough to tranſplant, ſome of them ſhould be planted in Pots to be ſhelter'd in *Winter*, and the others may remain where they were ſown, obſerving to keep them clear from Weeds, which is all the Culture they require. This Sort ſeldom continues longer than two or three Years, ſo that Seeds ſhould be ſown every other Seaſon to raiſe a Supply of young Plants.

Theſe Plants are ſuppoſed to have the ſame Virtues as *Savory*, to which they are nearly allied.

Moſt of the aromatic verticillate Plants will endure the Cold of the moſt ſevere *Winters* in *England*, provided they grow on rocky ſtony dry Ground, where they will be ſhort and ſtunted; and are alſo much ſtronger ſcented, than when they are ſown or planted on a richer Soil; nay, moſt of them will grow on old Walls and Buildings, where they will root into the Joints between the Stones or Bricks; and tho' they are expoſed to the ſevereſt Winds, yet will they reſiſt the Cold, when the Plants of the ſame Kinds, which are in the warmeſt Situations of the Garden, have been intirely deſtroyed. Of this there have been ſeveral Inſtances within the Memory of ſeveral Perſons now living, when all the *Roſemary*, and many other of the like aromatic Herbs, have been deſtroyed in the Gardens; when ſome few Plants, which were growing on old Walls, have eſcaped; whereby their Species have been preſerved in *England*.

THYMELÆA, [this Plant is ſo call'd of θύμȣ, *Thyme*, and ἐλαία, an *Olive-tree*; becauſe its Leaves are narrow as the *Thyme*, and thick as thoſe of the *Olive-tree*] Spurge Laurel, *or* Meſereon.

The *Characters* are;

The Flower conſiſts of one Leaf, is for the moſt part Funnel-ſhaped, and cut into four Segments, from whoſe Center riſes the Pointal, which afterwards becomes an oval Fruit, which is in ſome full of Juice, but in others is dry, in each of which is contained one oblong Seed.

The *Species* are;

1. Thymelæa *laurifolia ſemper-virens, ſeu laureola mas. Tourn.* The Spurge, *or* Dwarf Laurel.
2. Thymelæa *laurifolia ſemper-virens, foliis variegatis.* The ſtriped Spurge Laurel.
3. Thymelæa *lauri folio deciduo, ſive Laureola fœmina. Tourn.* The common Meſereon.
4. Thymelæa *lauri folio deciduo, flore albido, fructu flaveſcente. Tourn.* The Meſereon with white Flowers and yellowiſh Fruit.
5. Thymelæa *lauri folio deciduo, flore rubro.* The Meſereon with red Flowers.
6. Thymelæa *lauri folio deciduo, foliis ex luteo variegatis.* The common Meſereon with ſtrip'd Leaves.
7. Thymelæa *foliis lini. C. B. P.* Spurge-olive, or Laurel with Flax-leaves.
8. Thymelæa *Alpina linifolia humilior, flore purpureo odoratiſſimo. Inſt. R. H.* Dwarf Spurge-laurel of the Alps, with a Flax-leaf, and a very ſweet purple Flower.
9. Thymelæa *Alpina linifolia humilior, flore albo odoratiſſimo. Inſt. R. H.* Dwarf Spurge-laurel of the Alps, with a Flax-leaf, and a very ſweet white Flower.

10. THYMELÆA *villoſa minor Luſitanica, polygoni folio. Inſt. R. H.* Smaller hairy Portugal Spurge-laurel, with a Knot-graſs-leaf.

11. THYMELÆA *linariæ folio, vulgaris. Inſt. R. H.* Common Spurge-laurel, with a Toad-flax-leaf.

12. THYMELÆA *linariæ folio, Hiſpanica. Inſt. R. H.* Spaniſh Spurge-laurel, with a Toad-flax-leaf.

13. THYMELÆA *latifolia Hiſpanica, oleæ foliis. Inſt. R. H.* Broad-leav'd Spaniſh Spurge-laurel, with Olive-leaves.

14. THYMELÆA *argentea Italica, oleæ foliis. Inſt. R. H.* Silvery Italian Spurge-laurel, with Olive-leaves.

15. THYMELÆA *ſaxatilis, oleæ folio. Inſt. R. H.* Rocky Spurge-laurel, with an Olive-leaf.

16. THYMELÆA *Alpina, folio utrinque incano, flore albo. Inſt. R. H.* Alpine Spurge-laurel, with a Leaf hoary on both Sides, and a white Flower.

17. THYMELÆA *foliis polygalæ glabris. C. B. P.* Spurge-laurel, with ſmooth Milkwort-leaves.

18. THYMELÆA *foliis polygalæ villoſis. Inſt. R. H.* Spurge-laurel, with hairy Milkwort-leaves.

19. THYMELÆA *foliis chamelææ minoribus ſubhirſutis. C. B. P.* Spurge-laurel, with ſmaller-Widow-wail-leaves, which are ſomewhat hairy.

20. THYMELÆA *Hiſpanica, foliis myrti incanis. Inſt. R. H.* Spaniſh Spurge-laurel, with hoary Myrtle-leaves.

21. THYMELÆA *Pyrenaica juniperifolia, ramulis ſurrectis. Inſt. R. H.* Pyrenean Spurge-laurel, with a Juniper-leaf, and upright Branches.

22. THYMELÆA *foliis candicantibus, ſerici inſtar mollibus. C. B. P.* Spurge-laurel, with whitiſh ſoft Leaves reſembling Silk.

23. THYMELÆA *Cretica, oleæ folio, ſubtus villoſo. Tourn. Cor.* Spurge-laurel of Crete, with an Olive-leaf, hairy underneath.

24. THYMELÆA *Cretica, oleæ folio utrinque glabro. Tourn. Cor.* Spurge-laurel of Crete, with an Olive-leaf, ſmooth on both Sides.

25. THYMELÆA *Pontica, citrei foliis. Tourn. Cor.* Pontic Spurge-laurel, with Citron-leaves.

26. THYMELÆA *orientalis minima, laureolæ folio, floribus glomeratis albis. Tourn. Cor.* The leaſt eaſtern Spurge-olive, with the common Spurge-laurel-leaves, and white Flowers growing in Cluſters.

27. THYMELÆA *orientalis, buxi folio ſubtus villoſo, flore albo. Tourn. Cor.* Eaſtern Spurge-laurel, with a Box-leaf, hairy on the Underſide, and a white Flower.

28. THYMELÆA *orientalis, ſalicis folio, flore albo odoratiſſimo. Tourn Cor.* Eaſtern Spurge-laurel, with a Willow-leaf, and a white ſweet-ſcented Flower.

29. THYMELÆA *linifoliæ ſimilis, Africana, floribus pallidis odoratiſſimis. Prod. Par. Bat.* African Spurge-laurel like the firſt Sort, with pale ſweet-ſcented Flowers.

30. THYMELÆA *linifoliæ ſimilis, Africana, foliis lucidis, latioribus & obtuſis. Par. Bat.* African Spurge-laurel like the firſt Sort, with broader ſhining and obtuſe Leaves.

31. THYMELÆA *Africana, foliis lini, floribus in capitulum congeſtis. Oldenl.* African Spurge-laurel, with Flax-leaves, and Flowers collected in Heads.

32. THYMELÆA *Africana, roriſmarini folio anguſtiſſimo breviori. Oldenl.* African Spurge-laurel, with a very narrow and ſhorter Roſemary-leaf.

33. THYMELÆA *Africana, roriſmarini folio anguſtiſſimo longiori. Oldenl.* African Spurge-laurel, with a very narrow and longer Roſemary-leaf.

34. THYMELÆA *Africana, roriſmarini folio, floribus longioribus. Oldenl.* African Spurge-laurel, with a Roſemary-leaf, and longer Flowers.

35. THYMELÆA *Africana, ſanamundæ facie, ericæ foliis anguſtiſſimis. Prod. Par. Bat.* African Spurge-laurel, with the Face of Sanamunda, and very narrow Heath-leaves.

36. THYMELÆA *Africana Tarton-zaire ſimilis, floribus in capitulum congeſtis. Oldenl.* African Spurge-laurel, like the Tarton-zaire, with Flowers collected in a Head.

37. THYMELÆA *Africana, foliis ruſci. Oldenl.* African Spurge-laurel, with Butchers-broom-leaves.

38. THYMELÆA *Africana fruteſcens, jaſmini flore, foliis polygalæ. Oldenl.* African ſhrubby Spurge-laurel, with a Jaſmine-flower, and Leaves of Milkwort.

39. THYMELÆA *Capenſis, nepæ Theophraſti foliis aculeatis, flore parvo purpureo. Pluk. Phyt.* Spurge-laurel of the Cape of Good Hope, with prickly Furz-leaves, and a ſmall purple Flower.

40. THYMELÆA *Americana fruteſcens, roriſmarini folio, flore albo. Plum.* Shrubby American Spurge-laurel, with a Roſemary-leaf, and a white Flower.

The firſt of theſe Plants is found wild in Woods and other ſhady Places in divers Parts of *England*, but is often cultivated in Gardens for Variety; where, if it is planted in Wilderneſſes, or ſhady Walks, it will thrive very well; and being an Ever-green, and producing its Flowers in *Winter*, when few other Plants do flower, makes it the more acceptable. The ſecond Sort is a Variety of the firſt, which is preſerved for the Beauty of its ſtrip'd Leaves.

Both theſe Plants may be propagated by Suckers taken from the old Plants, or by Layers, which ſhould be taken off in *Autumn*, and planted in a ſtrong Soil and ſhady Situation, where, after they have taken Root, they will require little farther Care.

The ſeveral Sorts of *Meſereon* are propagated by ſowing their Seeds, the beſt Seaſon for which is in *Auguſt*, ſoon after they are ripe, when they begin to fall from the Trees: Theſe ſhould be ſown upon an Eaſt Border, where they may have only the Morning Sun, and covered about half an Inch with freſh Earth; in the *Spring* the Plants will appear, when they muſt be carefully clear'd from Weeds, and in dry Weather ſhould be often watered, which will greatly promote their Growth. In this Border they may remain two Years, by which Time they will be ſtrong enough to tranſplant; when there ſhould be a Spot of ſtrong freſh Earth prepared for them, into which they ſhould be planted in *Autumn*, in Rows three Feet diſtance, and the Plants eighteen Inches aſunder in the Rows, treating 'em afterwards in uſual Manner with other Kinds of Shrubs, while in this Nurſery; and when they are large enough to plant out for good, they may be taken up in *Autumn*, with a Ball of Earth to the Root of each Plant, and placed where they are to remain, which ſhould be in a ſtrong, moiſt Soil, and a ſhady Situation, where they will thrive and flower extreamly well.

Theſe Plants are great Ornaments to a Garden early in the *Spring*, before other Things are in flower, for if the Seaſon is mild they often flower in *January*, but in *February* they are always in Perfection. They ſeldom grow to be more than five or ſix Feet high in *England*, ſo ſhould be planted among other Shrubs of the ſame Growth.

The Sort with ſtrip'd Leaves may be propagated by budding or inarching it upon the plain Sort, becauſe the Seeds will not produce ſtrip'd Plants.

The ſeventh and fifteen following Sorts, grow wild in *Germany*, *Auſtria*, *Bohemia*, on the *Alps*, in *Spain*, *Portugal*, or the South of *France*, as they are particulariz'd in their Names: theſe Plants will live in the open Air in *England*, provided they are planted in a warm Situation.

The twenty-third, twenty-fourth, twenty-fifth, twenty-ſixth, twenty-ſeventh and twenty-eighth Sorts, were diſcovered by Dr. *Tournefort* in the *Levant*; from whence ſome of theſe Plants have been obtained, and are preſerved in curious Botanic Gardens for Variety. Theſe Sorts are alſo pretty hardy, ſo will endure the Cold of our ordinary *Winters* very well in the open Air, provided they are placed in a ſhelter'd Situation. All theſe Plants are propagated by Seeds, which ſhould be ſown in the *Autumn* as ſoon as they ar ripe; for if they are kept out of the Ground till *Spring*, the ſeldom ſucceed; and if any of them do grow, they will re main in the Ground a whole Year, before the Plants com up. Theſe Seeds ſhould be ſown on a ſhady Border, wher they may only enjoy two or three Hours of the Mornin Sun, and the Soil ſhould be cool and loamy; in dry Wea ther they muſt be duly water'd, and when the Plants ar come up, they ſhould be conſtantly kept clean from Weeds In this Border the Plants ſhould remain till *Michaelmas*, a which Time a freſh Border of loamy Earth ſhould be pre pared to receive the Plants, which ſhould alſo be in a ſhad Situation; then the Plants ſhould be carefully taken up ou of the Seed-bed, and planted in Rows about ſix or ſeve Inches aſunder, and about four Inches diſtance from eac other in the Rows. When theſe Plants have taken ne Root, they will require no farther Care, but to keep the clear from Weeds, and in dry Weather to refreſh them no and then with Water, which will promote their Growt If theſe Plants thrive well, they will be large enough t tranſplant by the following *Michaelmas*, into the Plac where they are deſign'd to remain; which ſhould always b on a pretty ſtrong loamy Soil, rather moiſt than dry; and it be under Cover of Trees, provided they are not t much over-hung, they will thrive better than in an open S tuation, where they are expoſed to the Sun.

Theſe Plants continue green throughout the Year, whic renders them worthy of a Place in good Gardens; where, they are rightly diſpoſed, they will afford an agreeable V riety. Moſt of theſe are low Shrubs, which ſeldom riſe a

bov

bove two or three Feet high, ſo are very proper to plant under Trees to fill up the Vacancies, where they will have a good Effect. The Seeds of the ſeventh Sort are uſed in Medicine, ſo that the Plants of this Kind are preſerved in Phyſick-gardens, but they make the meanneſt Appearance of all the Sorts.

The twelve Sorts which are laſt mentioned, are much tenderer than the former. All of theſe (except the laſt) grow near the *Cape of Good Hope*; from whence ſeveral of them have been brought into the *European* Gardens. Theſe Plants may alſo be propagated by Seeds, but as they very rarely produce their Seeds in *England*, ſo they are commonly propagated by laying down of their Branches; which, if rightly managed, will take Root in one Year. The beſt Time to lay down the Branches is in the Beginning of *April*; the Branches which are choſen to make Layers, ſhould be of the former Year, or at moſt but two Years old; theſe ſhould be a little twiſted at the Part which is laid in the Ground, which will cauſe them to root the ſooner: In dry Weather they muſt be duly watered, otherwiſe the Shoots will harden, which will prevent their putting out Roots. By the *April* following they will be rooted, when they may be cut off from the old Plants, and each planted into a ſmall Pot, filled with freſh Earth; and if they are plunged into a very moderate Hot-bed, it will forward their taking new Root. Theſe muſt be ſcreened from the Sun every Day till they are rooted; after which Time they muſt be inured to bear the open Air by Degrees; and in the Middle of *May* they ſhould be placed abroad in a ſheltered Situation, where they will make an agreeable Variety amongſt other exotick Plants.

Theſe Plants muſt be removed into the Green-houſe in *Autumn*, and placed where they may enjoy as much free Air as poſſible in mild Weather, but they muſt be protected from Froſt. During the *Winter* Seaſon they muſt be frequently refreſhed with Water, for they are pretty thirſty Plants; but in very cold Weather it muſt be given to them ſparingly. In *Summer* they muſt be placed abroad with the *Geraniums*, *Alaternoides's*, and other Plants of the ſame Country, and treated in the ſame Manner as hath been directed for thoſe; with which Management they will thrive very well. The Flowers of theſe Plants, being very ſmall, do not afford any great Pleaſure, but for the ſingular Oddneſs of the Leaves and Branches. Theſe Plants deſerve a Place in good Green-houſes, for the ſake of Variety.

The laſt Sort is more tender than any of the reſt, this being a Native of the warmer Parts of *America*. This was diſcovered by Father *Plumier*, in ſome of the *French* Settlements in *America*; and hath been obſerved growing in great Plenty at the *Havannah*, by the late Dr. *William Houſtoun*, who ſent the Seeds to *England*: It was alſo found by Mr. *Robert Millar* at *Campechy*, who alſo ſent the Seeds to *England*; from which many Plants have been raiſed.

The Seeds of this Plant ſhould be ſown in Pots of freſh Earth, and then plunged into a moderate Hot-bed of Tanners-bark; obſerving frequently to water the Pots, to keep the Earth moiſt, which will bring up the Plants in about ſix Weeks time. When theſe Plants are about two Inches high, they ſhould be ſhaken out of the Seed-pots, and each planted in a ſmall Pot filled with freſh loamy Earth; and then plunged into a moderate Hot-bed of Tanners-bark, where they muſt be ſhaded from the Heat of the Sun, until they have taken new Root; after which Time they muſt be treated after the ſame Manner as hath been directed for other exotick Plants, which are the Produce of the hotteſt Countries.

In this Hot-bed the Plants may remain till about *Michaelmas*, when the Nights will begin to be too cold for theſe Plants; therefore they ſhould be removed into the Stove, and plunged into the Bark-bed. During the *Winter* Seaſon, theſe Plants muſt be kept very warm, eſpecially while they are young, becauſe they make but little Progreſs the firſt Year; and if they are ſtunted the firſt *Winter*, they do not recover it in a long time after. Theſe Plants ſhould conſtantly remain in the Stove, and ſhould be treated in the ſame Manner as hath been directed for the *Suriana*.

THYMUS, [ſo called of ϑύος, *Odour*, becauſe it is a Plant very *odorous*; or of ϑυμὸ, *animal Spirit*, becauſe it is good in reviving the animal Spirits.] Thyme.

The *Characters* are;

It hath a labiated Flower, conſiſting of one Leaf, whoſe upper Lip is erect, and generally ſplit in two, and the under Lip is divided into three Parts; out of the Flower-cup ariſes the Pointal, accompanied by four Embryo's, which afterwards become ſo many Seeds, incloſed in a Husk, which was before the Flower-cup: To theſe Marks muſt be added, hard ligneous Stalks, and the Flowers gathered into Heads.

The *Species* are;

1. THYMUS *vulgaris, folio latiore. C. B. P.* Common broad-leafed Thyme.
2. THYMUS *vulgaris, folio tenuiore. C. B. P.* Common narrow-leafed Thyme.
3. THYMUS *vulgaris, folio latiore variegato.* Broad-leafed ſtriped Thyme.
4. THYMUS *capitatus, qui Dioſcoridis. C. B. P.* The true Thyme of the Antients.

There are ſeveral other Species of *Thyme*, which are preſerved in Botanick Gardens for Variety; but as they are ſeldom cultivated for Uſe, ſo I ſhall not enumerate them in this Place. The Sort with broad Leaves is the moſt common in *England*; this is cultivated in the Kitchen-gardens as a Soup Herb, and alſo for medicinal Uſe. The next two Sorts are preſerved in many Gardens for Variety, being equally as good as the firſt for Uſe: But the fourth Sort is leſs common in *England* than either of the former.

Theſe Plants may be propagated either by Seeds or parting their Roots; the Seaſon for either is in *March*. If it is done by ſowing the Seeds, it ſhould be done upon a Bed of light Earth, obſerving not to bury the Seeds too deep, which will cauſe them to rot: When the Plants are come up, they ſhould be carefully cleared from Weeds, and if the *Spring* ſhould prove dry, if they are watered twice a Week it will greatly promote their Growth; and in *June* the Plants ſhould be thinned, leaving them about ſix Inches aſunder each Way, that they may have Room to ſpread, and thoſe Plants which are drawn out may be tranſplanted into freſh Beds at the ſame Diſtance, obſerving to water them until they have taken Root, after which they will require no farther Care, but to keep them clear from Weeds, and in the *Winter* following they may be drawn up for Uſe.

But if theſe Plants are propagated by parting their Roots, the old Plants ſhould be taken up about the latter End of *March*, and ſlipt into as many Parts as can be taken off with Root; theſe ſhould be tranſplanted into Beds of freſh light Earth, at ſix or eight Inches Diſtance, obſerving if the Seaſon is dry to water them until they have taken Root, after which they muſt be duly weeded, and they will thrive, and ſoon be fit for Uſe.

In order to ſave Seeds of theſe Plants, ſome of the old Roots ſhould remain unremov'd in the Place where they were ſown the preceding Year; theſe will flower in *June*, and in *July* the Seed will ripen, which muſt be taken as ſoon as it is ripe, and beat out, otherwiſe the firſt Rain will waſh it all out of the Huſks.

Theſe Plants do root greatly in the Ground, and thereby draw out the Goodneſs of a Soil ſooner than moſt other Plants; ſo that whatever is ſown or planted upon a Spot of Ground whereon *Thyme* grew the preceding Year, will ſeldom thrive, unleſs the Ground be trenched deeper than the *Thyme* rooted.

THYME THE LEMON; *vide* Serpillum.

THYME THE MARUM; *vide* Marum.

THYME THE MASTICK; *vide* Maſtichina.

TILIA, [of *Telum*, a *Dart*, becauſe its Wood is uſed in making *Darts*.] The Lime *or* Linden Tree.

The *Characters* are;

The Flower conſiſts of ſeveral Leaves, which are placed orbicularly, and do expand in form of a Roſe, having a long, narrow Leaf, growing to the Foot-ſtalk of each Cluſter of Flowers, from whoſe Cup riſes the Pointal, which afterwards becomes a teſticulated Fruit, conſiſting of one Capſule, containing an oblong Seed in each.

The *Species* are;

1. TILIA *fœmina folio majore. C. B. P.* The common or broad-leafed Lime-tree.
2. TILIA *fœmina, folio minore. C. B. P.* The ſmall-leafed Lime-tree.
3. TILIA *foliis molliter hirſutis, viminibus rubris, fructu tetragono. Raii Syn.* The red-twig'd Lime-tree.
4. TILIA *Caroliniana, folio longius mucronato.* The Carolina Lime-tree.
5. TILIA *fœmina, folio majore variegato.* The ſtriped-leafed Lime-tree.

The three firſt mentioned Trees are very common in *England*, being cultivated in moſt Nurſeries, but the *Carolina* Sort is not at preſent very common; this was ſent from *Carolina*

rolina by Mr. *Mark Cateſby*, in the Year 1726, but as yet there does not appear any conſiderable Difference from the common Sort. That with ſtriped Leaves is preſerved by ſome for the ſake of Variety, but there is no great Beauty in it.

All theſe Trees are eaſily propagated by Layers, which in one Year will take good Root, and may then be taken off and planted in a Nurſery, at four Feet Diſtance Row from Row, and two Feet aſunder in the Rows; the beſt Time to lay them down and to remove them is at *Michaelmas*, when their Leaves begin to fall, that they may take Root before the Froſt comes on, though they may be tranſplanted any time from *September* to *March* in open Weather; but if the Soil is dry, it is much the better Way to remove them in *Autumn*, becauſe it will ſave a great Expence in watering them, eſpecially if the *Spring* ſhould prove dry. In this Nurſery they may remain four or five Years, during which Time the Ground ſhould be dug every *Spring*, and conſtantly kept clear from Weeds, and the large Side-ſhoots pruned off, to cauſe them to advance in Height; but the ſmall Twigs muſt not be pruned off from the Stems, becauſe theſe are abſolutely neceſſary to retain the Sap, for the Augmentation of their Trunks, which are apt to ſhoot up too ſlender, when they are entirely diveſted of all their lateral Twigs. If the Soil in which they are planted be a fat Loam, they will make a prodigious Progreſs in the Growth, ſo that in five Years time they will be fit to tranſplant out where they are to remain.

Theſe Trees were a few Years ſince greatly eſteemed for planting of Walks and Avenues near Habitations, becauſe in a few Years they would afford a pleaſant Shade, and might be removed, when grown to a large Stature, without Hazard, ſo that a Perſon might enjoy the Pleaſure of them in a ſhort Time: But of late they are much leſs valued, on account of their Leaves decaying early in *Autumn*, (eſpecially if the Soil be dry in which they are planted) ſo that they many times are almoſt deſtitute of Leaves by the Beginning of *September*, whereas the *Elm* continues in Beauty a full Month longer, and the Wood of the latter being much preferable to that of the former, has introduced theſe Trees inſtead of *Limes* in moſt of the modern Plantations.

The Timber of the *Lime-tree* is uſed by the *Carvers*, it being a ſoft, light Wood; as alſo by Architects for framing the Models of their Buildings; the *Turners* do alſo uſe it for making light Bowls, Diſhes, &c. but it is too ſoft for any ſtrong Purpoſes.

Theſe Trees will continue ſound a great Number of Years, and if planted in a good loamy Soil will grow to a conſiderable Bulk: I have meaſured one of theſe Trees which was near ten Yards in Girt two Feet above the Ground, and was then in a very thriving Condition; and Sir *Thomas Brown* mentions one of theſe Trees which grew in *Norfolk*, that was ſixteen Yards in Circuit, a Foot and half above Ground, in Height thirty Yards, and in the leaſt Part of the Trunk it was eight Yards and a half.

TINUS: Laurus Tinus, *vulgo*.

The *Characters* are;

The Flowers grow in Cluſters, and conſiſt of one Leaf, which is divided into five Parts toward the Top-part; theſe are ſucceeded by ſmall Fruit, ſhaped ſomewhat like an Olive, but are umbilicated, each containing one Pear-ſhaped Seed.

The *Species* are;

1. TINUS *prior. Cluſ. Hiſt.* The Baſtard ſhining-leafed Laurus Tinus, *vulgo*.
2. TINUS II. *Cluſ. Hiſt.* The rough-leafed Laurus Tinus, *vulgo*.
3. TINUS III. *Cluſ. Hiſt.* The ſmall-leafed Laurus Tinus, *vulgo*.
4. TINUS *prior Cluſii, folio atroviridi ſplendente.* The ſhining-leafed Laurus Tinus, *vulgo*.
5. TINUS *prior Cluſii foliis ex albo variegatis.* The ſtriped ſhining-leafed Laurus Tinus.
6. TINUS II. *Cluſii, foliis ex luteo variegatis.* The ſtriped rough-leafed Laurus Tinus.

Theſe Plants are greatly propagated in the Gardens near *London* for their Beauty, the Leaves always remaining green, and their Flowers are produced in great Plenty in the *Winter* Seaſon, when few other Shrubs do flower.

Theſe Plants were a few Years ſince preſerved in Pots and Tubs, and placed in the Green-houſe in *Winter*, with Oranges, Myrtles, and other exotick Trees; but of late Years they have been planted in the open Ground, where they reſiſt the Cold of our ordinary *Winters* very well, and are rarely injured, except in very ſevere Froſts, and then they are ſeldom deſtroyed, tho' their Heads may be killed, (as was the Caſe with many of theſe Trees in the Year 1728) yet thoſe which were left undiſturbed ſhot out freſh again the following *Summer*, and have ſince made good Plants; which ſhould caution People from rooting out Plants too ſoon, when they may ſeem to be killed by Froſt.

Theſe Plants may be propagated by laying down their tender Shoots in the *Spring*, which, if kept clear from Weeds and duly watered in dry Weather, will take Root by the ſucceeding *Spring*, when they ſhould be taken off and tranſplanted into a mellow loamy Soil, (but not too wet) at three Feet diſtance Row from Row, and eighteen Inches aſunder in the Rows, obſerving to lay ſome Mulch upon the Surface of the Ground about their Roots, and in dry Weather to refreſh them with Water until they have taken Root.

There ſhould alſo be ſome ſtrait Stakes fix'd down by the Side of each Plant, to which they ſhould be faſten'd, in order to render their Stems ſtrait, otherwiſe they will be crooked and unſightly. But it is not proper to have theſe Plants more than two Feet high in clear Stems, becauſe when their Heads are advanced above Sight, the Beauty of the Plants are loſt, and they are in greater Danger of being deſtroy'd in bad Weather: Therefore, when their Stems are two Feet high, their upright Shoots ſhould be ſtopp'd, in order to force out lateral Branches, which may be ſo prun'd in the growing Seaſon, as to form 'em into regular Heads; but this ſhould not be done with Sheers (as is the common Practice, whereby their Leaves are cut, and render'd very unſightly), but rather ſkilfully pruned with a Knife, allowing their Branches a proportionable Diſtance to the Breadth of their Leaves, which will be cloſe enough to render them beautiful, and at the ſame time will encourage their Flowering: For when they are continually clipp'd, their Branches are very weak, and do often decay in the Middle, and their Flowers are never ſo large, nor produc'd in ſo great Plenty as when they have a greater Diſtance allow'd to their Shoots.

In this Nurſey the Plants may remain four or five Years, during which time they ſhould be carefully clear'd from Weeds, and the Ground dug every *Spring*; in doing of which their Roots ſhould be carefully cut round, to cauſe 'em to produce more Fibres, whereby they may be removed with greater Safety, becauſe the Earth will be the better ſupported by their Roots. The beſt Time to tranſplant them is about the Beginning of *April*, as hath been directed for moſt Sorts of Evergreens, that being the Seaſon they begin to ſhoot.

Theſe Shrubs are very ornamental, when planted in the lower Part of Clumps, and other Plantations of Evergreens, if they are mix'd with other Plants of the ſame Growth; and in theſe Plantations they will not be ſo liable to ſuffer by Froſt, becauſe their Stems will be defended by the neighbouring Plants.

There are ſome who make Hedges of theſe Plants, but they are by no means proper for that Purpoſe, becauſe their Leaves are large, which occaſions their Branches to be produced at a farther Diſtance, and theſe when cut do appear very unſightly; beſides, by the frequent cutting of them, it prevents their flowering, ſo that the greateſt Beauty of the Plants is loſt; for they ſhould never be pruned after the Beginning of *May*, unleſs ſome very luxuriant ſhoots are produced, which grow greatly out of Order; theſe may be ſhorten'd, or entirely diſplaced, according as the Plants may require; and this one Pruning every *Spring* will be ſufficient to keep 'em conſtantly in Order, without injuring their flowering, which ſhould always be avoided.

TITHYMALOIDES, [of τιθύμαλος and εἶδος, *Shape.*] Baſtard Spurge.

The *Characters* are;

The Flower conſiſts of one Leaf, and is in Shape ſomewhat like a Slipper; whoſe Pointal afterwards becomes a tricapſular Fruit, like that of Spurge.

The *Species* are;

1. TITHYMALOIDES *fruteſcens, folio Myrti ampliſſimo. Tourn.* The American, ſhrubby, laurel-leav'd Spurge, *vulgo*.
2. TITHYMALOIDES *fruteſcens, foliis nerii. Plum.* Shrubby Baſtard Spurge with an Oleander Leaf.

Theſe Plants are very common in the warm Parts of *America*, where the firſt is known by the Name of *Poiſon-weed*, under which Appellation I received it from *Barbados*;

this Sort is now pretty common in the Gardens of thoſe who are curious in preſerving tender exotick Plants; but the ſecond Sort is yet very rare in the *Engliſh* Gardens.

They are both propagated by Cuttings, which may be taken from the Plants during any of the *Summer* Months, and after having lain in a dry Place for a Fornight or three Weeks, until the wounded Part be healed over, they ſhould be planted into ſmall Pots, fill'd with light, ſandy Earth, mix'd with Lime-rubbiſh, and then plunged into a Hot-bed of Tanners-bark, obſerving now and then to refreſh them gently with Moiſture; but they ſhould never receive much Wet, which will rot them.

After they have taken Root they may have a greater ſhare of Air, by raiſing the Glaſſes, but they muſt never be expos'd to the open Air: In this Bed they may remain until the Beginning of *October*, when they muſt be removed into the Stove, and placed, with the *Melon* and *Torch Thiſtle*, in a warm, dry Situation, and during the *Winter* Seaſon they ſhould have very little Water, which if given in Plenty, ſeldom fails to rot 'em. In the *Spring* theſe Plants ſhould be again placed into a Bark-bed, which will greatly promote their Growth, and will cauſe 'em to produce Flowers, which they ſeldom do when kept dry upon Shelves in the Stove, nor will they make any conſiderable Progreſs in ſuch a Situation.

Theſe Plants are preſerved for their odd Appearance amongſt other ſucculent Plants, their Leaves being very large, thick, and full of a milky acrid Juice.

TITHYMALUS, [τιθύμαλος, ſo called of τιθὴ a *Pap*, or *Teat*, and μαλακὸς, *ſoft*, q. d. *ſoft Pap*, becauſe this Plant produces Milk. One Sort is call'd *Characias*, *i*, *e*. belonging to a Valley, of χαρακόω, to *make a Trench*, on Account of its growing in a Valley. Another Sort is called *Peplos*, which was an Ornament that Women made uſe of, which being ſpread out, ſerved for a Veil. A third Sort is call'd *Cataputia*, a *Medicament* that is ſwallow'd at one Gulp.] Spurge.

The *Characters* are;

The Flower conſiſts of one Leaf, which is of the globous, Bell-ſhape, cut into ſeveral Moon-ſhap'd Segments, and encompaſſed by two little Leaves, which ſeem to perform the Office of a Flower-cup; the Pointal, which is for the moſt part triangular, riſes from the Bottom of the Flower, and afterwards becomes a Fruit of the ſame Shape, divided into three ſeminal Cells, in each of which is contained one oblong Seed. To theſe Notes ſhould be added, It has a milky, acrid Juice abounding in every Part of the Plant.

The *Species* are;

1. TITHYMALUS *latifolius, cataputia dictus. H. L.* Broad leav'd Spurge, *called* Cataputia.
2. TITHYMALUS *characias amygdaloides. C. B. P.* Wood Spurge with Almond-like Leaves.
3. TITHYMALUS *characias amygdaloides, foliis eleganter variegatis. Flor. Bat.* Wood Spurge, with beautiful ſtrip'd Leaves.
4. TITHYMALUS *maritimus. C. B. P.* Sea Spurge.
5. TITHYMALUS *myrſinites latifolius. C. B. P.* Broad Myrtle-leav'd Spurge.
6. TITHYMALUS *paluſtris fruticoſus. C. B. P.* Shrubby Marſh Spurge, *commonly called* the Greater Eſula of the Shops.
7. TITHYMALUS *foliis pini, forte Dioſcoridis pityuſa. C. B. P.* Pine-leav'd Spurge, *called* the Leſſer Eſula of the Shops.
8. TITHYMALUS *Indicus fruteſcens. Raii Hiſt.* Indian ſhrubby Spurge.
9. TITHYMALUS *Indicus vimineus penitus aphyllos. Boerh. Ind.* Indian Spurge with ſlender ſtraggling Branches without Leaves.
10. TITHYMALUS *arboreus. Alpin.* Tree Spurge with Myrtle Leaves.
11. TITHYMALUS *Creticus characias anguſtifolius, villoſus & incanus. T. Cor.* Woody Spurge of Candia, with narrow, hairy, and hoary Leaves.
12. TITHYMALUS *helioſcopius. C. B. P.* Sun-ſpurge, or Wartwort.
13. TITHYMALUS *rotundis foliis, non crenatis. H. L.* Petty-ſpurge.
14. TITHYMALUS *maritimus ſupinus annuus, peplis dictus. Raii Syn. Ed.* 3. Small purple Sea ſpurge.
15. TITHYMALUS *ſive eſula exigua. C. B. P.* Small dwarf annual Spurge.
16. TITHYMALUS *maritimus minor Portlandicus. Raii Syn. Ed.* 3. Small Sea or Portland Spurge.
17. TITHYMALUS *platyphyllos Fuchſii. J. B.* Broad-leav'd Spurge.
18. TITHYMALUS *ſegetum longifolius. Cat. Cant. App.* Long-leav'd Corn-ſpurge.
19. TITHYMALUS *verrucoſus. J. B.* Rough fruited Spurge.
20. TITHYMALUS *Hybernicus. Merr. Pin.* Knotty rooted Spurge, *commonly called* Mackinboy by the *Iriſh*.
21. TITHYMALUS *characias rubens peregrinus. C. B. P.* Foreign red Wood-ſpurge.
22. TITHYMALUS *ſylvaticus, lunato flore. C. B. P.* Wood-ſpurge, with Flowers ſhap'd like a Creſcent.
23. TITHYMALUS *characias, radice repente. H. R. Monſp.* Wood-ſpurge, with a creeping Root.
24. TITHYMALUS *characias anguſtifolius. C. B. P.* Narrow-leav'd Wood-ſpurge.
25. TITHYMALUS *characias, folio ſerrato. C. B. P.* Wood-ſpurge, with Leaves ſawed on their Edges.
26. TITHYMALUS *characias, radice pyriformi. Mor. H. R. Blæſ.* Wood-ſpurge, with a pear-ſhap'd Root.
27. TITHYMALUS *characias, ſalicis minoris folio. Mor. R. H. Blæſ.* Wood-ſpurge, with a ſmaller Willow-leaf.
28. TITHYMALUS *tuberoſa pyriformi radice. C. B. P.* Spurge, with a tuberoſe Root, ſhap'd like a Pear.
29. TITHYMALUS *linariæ folio, lunato flore. Mor. Hort. Blæſ.* Spurge, with a toad-flax Leaf, and a moon-ſhap'd Flower.
30. TITHYMALUS *arboreus linifolius. H. R. Par.* Tree-ſpurge, with Flax-leaves.
31. TITHYMALUS *amygdaloides anguſtifolius. Tabern. Icon.* Narrow-leav'd Spurge.
32. TITHYMALUS *orientalis, latiſſimo folio, villoſus, flore lunato. Tourn. Cor.* Eaſtern hairy broad-leav'd Spurge, with a moon-ſhap'd Flower.
33. TITHYMALUS *orientalis, ſalicis folio, caule purpureo, flore magno. Tourn. Cor.* Eaſtern Spurge, with a Willow-leaf, a purple Stalk, and a large Flower.
34. TITHYMALUS *orientalis, cypariſſias patulus, foliis ſuperioribus haſtatis, flore minimo. Tourn. Tor.* Eaſtern cypreſs Spurge, with ſpreading Branches, the upper Leaves ſhap'd like a Spear, and a very ſmall Flower.
35. TITHYMALUS *arboreus, humilior & patulus, latiore folio. Tourn. Cor.* Low ſpreading Tree-ſpurge, with a broader Leaf.
36. TITHYMALUS *arboreus, humilior & patulus, anguſtiore folio. Tourn. Cor.* Low ſpreading Tree-ſpurge, with a narrower Leaf.
37. TITHYMALUS *Græcus, amygdali folio acutiſſimo & glauco, caule purpureo. Tourn. Cor.* Greek Spurge, with a ſharp-pointed Almond-leaf, and a purple Stalk.
38. TITHYMALUS *Græcus helioſcopius maximus, foliis eleganter crenatis. Tourn. Cor.* Greateſt Sun-ſpurge of Greece, with Leaves elegantly notched.
39. TITHYMALUS *orientalis paluſtris, tuberoſa radice, lathyridis facie. Tourn. Cor.* Marſh eaſtern Spurge, with a tuberoſe Root, and the Face of Cataputia minor.
40. TITHYMALUS *orientalis, latiſſimo folio, villoſus, flore aureo, ſegmentis rotundioribus. Tourn. Cor.* The broadeſt-leav'd hairy eaſtern Spurge, with a golden Flower, having rounder Segments.
41. TITHYMALUS *orientalis, anacampſerotis folio flore magno criſtato. Tourn. Cor.* Eaſtern Spurge, with an Orpine-leaf, and a large creſted Flower.
42. TITHYMALUS *orientalis, anacampſerotis folio, tenuiſſime ſerrato, flore minori non criſtato. Tourn. Cor.* Eaſtern Spurge, with an Orpine-leaf finely ſaw'd, and a ſmaller Flower not creſted.
43. TITHYMALUS *orientalis, latiſſimo folio glauco & glabro. Tourn. Cor.* Eaſtern Spurge, with a very broad ſmooth ſea-green Leaf.
44. TITHYMALUS *orientalis, patulus & humilior, ſalicis folio villoſo. Tourn. Cor.* Low ſpreading eaſtern Spurge, with a hairy Willow-leaf.
45. TITHYMALUS *orientalis, linariæ folio, humillimus. Tourn. Cor.* The loweſt eaſtern Spurge, with a toad-flax Leaf.
46. TITHYMALUS *arboreus, caule corallino, folio hyperici, pericarpio barbato. Boerh. Ind. alt.* Tree-ſpurge, with a red Stalk, a St. John's-wort Leaf, and a bearded Cover to the Fruit.
47. TITHYMALUS *arboreus altiſſimus, folio ſalicis, caulibus rubentibus. Boerh. Ind. alt.* The talleſt Tree-ſpurge, with a Willow-leaf, and reddiſh Stalks.
48. TITHYMALUS *Lugdunenſis, laureolæ folio. D. Goiſſon. Boerh. Ind. alt.* French Spurge, with a Spurge-laurel-leaf.

49. Tithymalus *marinus, folio retuſo, Terracinenſis. Barr. Obſ.* Sea-ſpurge, with a blunt Leaf.

50. Tithymalus *folio longo glauco, caule rubro, capſulis verrucoſis, elatior Siculus. Raii Hiſt.* Taller Spurge of Sicily, with a long ſea-green Leaf, a red Stalk, and warted Seed-veſſels.

51. Tithymalus *amygdali folio anguſtiori, Montis Pollini. H. Cath.* Sicilian Spurge, with a narrow Almond-leaf.

52. Tithymalus *amygdali folio breviori latiori hirſuto, Montis Pollini. H. Cath.* Sicilian Spurge, with a broader and ſhorter hairy Almond-leaf.

53. Tithymalus *arboreus, tuberoſa radice, mollioribus foliis, ſemine verrucoſo aſpero. Bocc. Muſ.* Tree-ſpurge, with a knobbed Root, ſoft Leaves, and a rough warted Seed.

34. Tithymalus *arboreus Africanus. Inſt. R. H.* African Tree-ſpurge.

55. Tithymalus *arboreus Americanus, cotini folio. Hort. Amſt.* American Tree-ſpurge, with a Venice Sumach-leaf.

56. Tithymalus *Americanus arboreſcens, cotini foliis minoribus, & verticillatim naſcentibus. Plum. Cat.* American Tree ſpurge, with ſmaller Venice Sumach-leaves, growing in Whorles.

57. Tithymalus *Americanus arboreſcens, foliis linariæ. Plum. Cat.* American Tree-ſpurge, with toad-flax Leaves.

58. Tithymalus *qui peplis maritima fruticoſa geniculata. Sloan. Cat.* Shrubby American Sea-ſpurge, with a jointed Stalk.

59. Tithymalus *Americanus characias variegatus, flore albo, fructu villoſo. Houſt.* American ſtrip'd Spurge, with a white Flower, and a hairy Fruit.

60. Tithymalus *Curaſſavicus, ſalicis & atriplicis foliis hirſutis, caulibus ſubrubentibus. Prod. Par. Bat.* Spurge from Curaſſo, with hairy Leaves, like the Willow or Orach, and reddiſh Stalks.

61. Tithymalus *Curaſſavicus, ſalicis & atriplicis foliis glabris, caulibus viridantibus. Prod. Par. Bat.* Spurge from Curaſſo, with ſmooth Willow or Orach-leaves, and greeniſh Stalks.

62. Tithymalus *Americanus annuus erectus, caule triangulari, foliis variis. Houſt.* Upright annual American Spurge, with a triangular Stalk, and variable Leaves.

63. Tithymalus *Americanus annuus erectus latifolius, foliolis juxta flores albis. Houſt.* Upright annual American Spurge, with broad Leaves, and the ſmall Leaves near the Flowers white.

64. Tithymalus *maritimus, Barbadenſis & Bermudenſis, ſeu paralius minor Americanus ramoſiſſimus. Pluk. Phyt.* American branching Sea-ſpurge.

65. Tithymalus *dulcis, parietariæ foliis hirſutis, floribus ad caulium nodos conglomeratis. Sloan. Cat.* Sweet American Spurge, with hairy Pellitory-leaves, and Flowers growing in Cluſters from the Joints of the Stalk.

66. Tithymalus *erectus acris, parietariæ foliis glabris, floribus ad caulium nodos conglomeratis. Sloan. Cat.* Upright acrid Spurge, with ſmooth Pellitory-leaves, and Flowers growing in Cluſters from the Joints of the Stalk.

67. Tithymalus *Americanus annuus erectus ramòſiſſimus, ocymi caryophyllati foliis. Houſt. Cat.* Upright annual branching American Spurge, with Leaves like the Buſh-baſil.

68. Tithymalus *maritimus Americanus procumbens, foliis ſubrotundis rarioribus, fructu majore. Houſt.* Trailing American Sea-ſpurge, with roundiſh Leaves, and a larger Fruit.

69. Tithymalus *Americanus procumbens, foliis ſubrotundis, & ab alterâ parte auritis. Houſt.* Trailing American Spurge, with roundiſh Leaves, and in other Parts the Leaves are eared.

70. Tithymalus *exiguus glaber, nummulariæ folio. Inſt. R. H.* Small ſmooth Spurge, with a Moneywort-leaf.

71. Tithymalus *exiguus villoſus, nummulariæ folio. Inſt. R. H.* Small hairy Spurge, with a Moneywort-leaf.

The firſt is a biennial Plant, which will ſcatter its Seeds, and the Plants will come up without any Care, which will flower and ſeed the following *Summer*, after which the Plants will die; theſe Plants come up much better when the Seeds fall of themſelves, than if ſown with great Care, nor will they bear Removing, unleſs it be done while they are young; becauſe they generally ſend forth a Tap-root, which is often broken by tranſplanting, and thereby the Plant deſtroy'd. This is order'd by the *College of Phyſicians* to be uſed in Medicine, under the Title of *Cataputia minor*, for which Reaſon it is preſerv'd in ſome Gardens, though there is no great Beauty in the Plant.

The ſecond Sort is found wild in Woods and other ſhady Places in divers Parts of *England*, but is worthy of a Place in ſmall Wilderneſs Quarters, or in other ſhady Plantations, where it will thrive very well, and in the *Spring* will produce great Tufts of Flowers, which although not very beautiful, yet are of a ſingular Figure and Colour, and will add to the Variety of the Place. Theſe Plants may be taken out of the Woods in *Autumn*, and tranſplanted into the Places where they are deſign'd, in which, if they are once eſtabliſh'd, they will ſow their Seeds, and thereby be continued; but if they are not placed under the Shelter and Shadow of Trees, they will not thrive ſo well.

The third Sort is a Variety of the ſecond; the Leaves of this Kind are beautifully ſtrip'd, ſo as to appear of three Colours: This may be propagated by Cuttings, which ſhould be planted in Pots, filled with light ſandy Earth, and placed in the Shade until they have taken Root, after which they may be placed amongſt other curious Plants, where they may be ſcreen'd from the Violence of the Sun in *Summer*, and in *Winter* they muſt be ſhelter'd under a Frame from hard Froſt, which will deſtroy them, but they muſt have the free Air in mild Weather, and not too much Wet in *Winter*.

The fourth Sort is found wild upon the Sea-Coaſts in ſeveral Places in *England*, from whence it has been tranſplanted into ſeveral Gardens: This may be propagated by ſowing the Seeds, or by Cuttings, which muſt be planted in the *Spring*, upon a gravelly poor Soil, in which this Plant will endure the Cold of our ordinary *Winters* very well, but in very ſevere Froſts it is often deſtroy'd. This is preſerved in ſome Gardens, more for the Sake of its Variety than Beauty.

The fifth Sort may alſo be propagated either by ſowing its Seeds or planting Cuttings, in the ſame manner as the former, but muſt have a dry Soil, and a warm Situation, otherwiſe the Cold will deſtroy it in *Winter*. This Plant trails upon the Ground, ſo ſhould be planted at a Diſtance from other Plants, becauſe, if it be over-hung by 'em, it will not thrive, and the Branches of this will many times extend themſelves two Feet from the Root, ſo that if it has not Room, they will rot and die away.

The ſixth Sort grows wild in marſhy Places in *France*, *Italy*, and *Germany*, but in *England* it is preſerved in ſome curious Botanick Gardens, it being an officinal Plant. This may be propagated by parting the Roots, and planting Cuttings in the *Spring*, which muſt be done in a light Soil and an open Situation, where it will grow four or five Feet high, and become very ſhrubby; ſo that the Plants muſt be allowed at leaſt two Feet Room to grow, otherwiſe they will over-bear each other, or whatever Plants ſtand near them. There is not much Beauty in this Sort; but as it is a medicinal Plant, it ſhould have a Place in Phyſick Gardens.

The ſeventh Sort is a very hardy Plant, and propagates itſelf by its creeping Roots, ſo that if it be not confined in Pots, it will ſpread over the Ground wherever it is planted, ſo as not to be eaſily kept within Bounds. This being a medicinal Plant ſhould alſo have a Place in Phyſick-gardens, but there is not much Beauty in it to recommend it to the Curious.

The eighth, ninth, and tenth Sorts are tender Plants, which come from warm Countries; and in *England* are preſerved with great Care in Stoves, amongſt other curious ſucculent Plants. Theſe are propagated by Cuttings, which ſhould be cut from the old Plants at a Joint, and laid in a dry Part of the Stove for a Fortnight, that the wounded Part may heal over; then they ſhould be planted in ſmall Pots filled with light ſandy Earth, mixed with Lime-rubbiſh, and plunged into a Hot-bed of Tanners-bark, where they ſhould remain until they have taken Root, after which they ſhould be inured to the Air by Degrees, and then be removed into the Stove, where they muſt conſtantly be kept, for they are too tender to be expoſed abroad in the Heat of *Summer*; therefore they ſhould be placed near the Glaſſes of the Stove in *Summer*, where they may have Air in very hot Weather, but they muſt not have much Wet, being very full of Moiſture, and ſubject to rot if over-watered. In *Winter* they muſt be ſet in a warm Part of the Stove, and ſhould have very little Wet during that Seaſon: With this Management theſe Plants will thrive and grow very large, but they ſeldom produce Flowers in this Country.

The eleventh Sort was found by Monſieur *Tournefort* in the *Levant*, and by him brought into *Europe*, by the Name here given to it, tho' many curious Botaniſts are not ſatisfied how it differs from the *Tithymalus characias rubens peregrinus* of *Caſpar Bauhinus*. This has a great deal of the Appearance of our *Wood Spurge*, but the Stalks are redder, and the Flowers are much fairer: It may be propagated by Cuttings, which ſhould be planted in Pots, filled with light ſandy Earth, and in *Winter* muſt be ſheltered, otherwiſe it is apt to periſh with ſevere Cold. In *March* it flowers, at which Time it makes a beautiful Appearance, and is worthy of a Place in every good Garden.

The twelfth, thirteenth, fourteenth, fifteenth, ſixteenth, ſeventeenth, eighteenth and nineteenth Sorts, are annual Plants, which grow wild in ſeveral Parts of *England*, ſo are rarely admitted into Gardens; but ſome of them generally come up as Weeds in moſt cultivated Lands. The moſt common of theſe are the twelfth, thirteenth and fifteenth Sorts, the others growing but in ſome particular Parts of *England* wild. Theſe Plants abound with a milky Juice, which ſome People apply to Warts to get them off; but this ſhould be done with Diſcretion, otherwiſe there may be Danger of injuring the Part where it is applied, becauſe it is a great Cauſtick. All theſe Sorts will come up from Seeds, whenever they are ſcattered; ſo that whoever hath a Deſire to preſerve them, need only allow them a Place; for they will require no Care to propagate them.

The twentieth Sort grows wild in ſeveral Parts of *Ireland*, where it was formerly much in uſe amongſt the Natives of that Country, and was the chief Phyſick uſed by them for all Diſtempers, till of late, that they have gotten the Knowledge of *Mercury*, which has obtained ſo much with them, as to put this Plant quite out of Uſe.

This is an abiding Plant, having thick knobbed Roots, which may be ſeparated every other Year, to propagate the Plant by thoſe who deſire it; tho' indeed it is rarely preſerved but in Botanick Gardens, for the ſake of Variety. It is very hardy, and will thrive in almoſt any Soil or Situation, and dies to the Root every *Autumn*, and the *Spring* following comes up again. This may be planted in Wilderneſſes, where it will thrive very well under the Drip of Trees, and will ſerve to fill up in ſuch Places where few other better Plants will live.

The twentyfirſt Sort is ſuppoſed to grow wild in *England*; but I believe ſome People have taken the common *Woodſpurge* for this, when it has appeared with Stalks ſomewhat redder than ordinary. This, and the ten following Sorts, grow wild in *France*, *Italy* and *Germany*, from whence they have been procured by ſome Perſons who are curious in Botany. All theſe are very hardy Plants, which may be propagated by Seeds, which may be ſown in a Bed of freſh Earth in the *Spring*; and when the Plants come up, they will require no farther Care, but to clear them from Weeds; and where they are too thick, ſome of them ſhould be drawn out, to give thoſe Plants, which are deſigned to remain, Room to grow until *Michaelmas*, when they ſhould be planted into Woods, and other Places covered with Trees; where they will make an agreeable Variety.

The fourteen Sorts next following were diſcovered by Dr. *Tournefort* in the *Levant*; from whence he ſent their Seeds to the Royal Garden at *Paris*, where many of them were raiſed, and have ſince been communicated to ſeveral Perſons who are curious in Botany in *England*. Theſe are all of them very hardy Plants, ſo will be very proper to intermix with the Sorts before mentioned, in Wilderneſs Quarters; where, if they have a dry Soil, they will thrive very well, and make an agreeable Appearance. Some of theſe Sorts die to the Root every *Autumn*, and riſe again the following *Spring*; but they will not require any Care to preſerve them; the only Culture they require is to keep them from being overborn by very large Weeds.

The fortyſixth, fortyſeventh and fortyeighth Sorts are ſomewhat tenderer than either of the former; therefore ſome Plants of each Kind ſhould be kept in Pots to be ſheltered in *Winter*, for fear thoſe which are planted ſhould be deſtroy'd. Theſe may be propagated by Cuttings, which ſhould be taken off from the old Plants a Week before they are planted, and laid in a dry Place, that the wounded Part may heal, otherwiſe they will rot. Theſe Cuttings may be planted in a Bed of freſh undunged Earth, and ſhaded with Mats until they have taken Root; after which Time they will require no farther Care, but to keep them clear from Weeds till *Michaelmas*; when they ſhould be tranſplanted ſome of them into Pots, and the others under Trees on a dry Soil, and in a warm Situation, where they will endure the Cold of our ordinary *Winters* very well; but in ſevere Froſts they are frequently deſtroyed. Thoſe Plants in Pots ſhould be removed into Shelter towards the End of *October*, and placed where they may have as much free Air as poſſible in mild Weather, otherwiſe their Shoots will be weak and unſightly; for if they are only protected from very hard Froſts, it is all theſe Plants require. Theſe Sorts grow to the Height of ſix or ſeven Feet, and may be allowed a Place in Gardens, for the ſake of Variety.

The fortyninth Sort is a very hardy Plant, which propagates itſelf very faſt by its creeping Roots; ſo ſhould not be planted near better Plants, becauſe it will ſpread ſo far, and intermix its Roots with them, and deſtroy them. This Sort may be planted in ſome Quarters under Trees, where the Soil is very poor, in which it will thrive and fill up better than moſt other Plants.

The fiftieth and fiftythird Sorts are ſomewhat tender, ſo ſome of the Plants ſhould be preſerved in Pots, and ſheltered in *Winter*, and the others may be planted on a dry Soil, and in a warm Situation, where they will endure the Cold of our common *Winters*, and will add to the Variety.

The fiftyfirſt and fiftyſecond Sorts are biennial Plants, which ſeldom continue long after they have perfected their Seeds. Theſe are very hardy Plants, ſo will grow in any Situation, provided they have a dry Soil; and if their Seeds are permitted to ſcatter, the Plants will come up and thrive without any other Care than to keep them from being overborn by large Weeds.

The fiftyfourth Sort is tenderer than either of the former, ſo muſt be placed in a warm Greenhouſe in *Winter*, otherwiſe it will not live in this Country. This is propagated by Cuttings, which muſt lie to dry a Fortnight before they are planted; for as the whole Plant abounds with a milky Juice, ſo, if the wounded Parts are not well healed over before they are planted, they are very ſubject to rot. The beſt time for planting of theſe Cuttings is in *July*, that they may be well rooted before *Winter*. Theſe ſhould be planted each into a ſeparate ſmall Pot, and if they are plunged into a very moderate Hot-bed, it will cauſe them to root the ſooner. They ſhould be now and then refreſhed with Water, but it muſt not be given them in large Quantities, leſt it rot them. When they are rooted, they muſt be inured to bear the open Air by Degrees, into which they may be removed, and placed in a warm Situation, where they may remain till *Michaelmas*, when they muſt be removed into the Green-houſe, and placed in the warmeſt Part of it. During the *Winter* Seaſon theſe Plants muſt have but little Water, eſpecially if they have no artificial Heat; for Moiſture is very apt to rot theſe Plants in cold Weather.

The fiftyfifth and fiftyſixth Sorts grow plentifully in the Iſland of *Jamaica*, and in ſeveral other Places in the *Weſt-Indies*. Theſe are very tender Plants, ſo muſt be preſerved in warm Stoves, otherwiſe they will not live in this Country. They may be propagated by Cuttings in the *Summer* Months, which muſt be treated in the ſame Manner as hath been directed for the *Euphorbiums*; with which Management theſe Plants will thrive extremely well, and will make an agreeable Variety amongſt other tender exotick Plants in the dry Stove.

The fiftyſeventh Sort was diſcovered by Father *Plumier* in the *French* Settlements in *America*, and was found by the late Dr. *Houſtoun* at the *Havannah*, growing in great Plenty. This Sort may be propagated by Cuttings as the former, and ſhould be treated in the ſame Manner.

The fiftyeighth Sort grows plentifully in *Jamaica*, and ſeveral other Parts of *America*. This may be propagated by Seeds, which ſhould be ſown on a Hot-bed early in the *Spring*; and when the Plants are come up, they ſhould be each tranſplanted into a ſeparate ſmall Pot filled with freſh, light, ſandy Earth, and then plunged into a Hot-bed of Tanners-bark, where they ſhould be ſhaded from the Sun until they have taken Root; after which time they ſhould have free Air admitted to them in warm Weather, and muſt be refreſhed two or three times in a Week with Water; but as theſe Plants are full of Juice, ſo they ſhould not have too much Moiſture, leſt it rot them. In this Hot-bed the Plants may remain till about *Michaelmas*, when they ſhould be removed into the dry Stove; and may afterwards be treated in the ſame Manner as the three former Sorts.

The fiftyninth Sort was found growing plentifully on the ſandy barren Ground at *La Vera Cruz*, by the late Dr. *Houſtoun*, who obſerved, that all the Plants which he ſaw were variegated, ſo that he ſuppoſed they continued to come up ſo from the Seeds. This is a very beautiful Plant, and being tender, muſt be treated in the ſame Manner as the Sorts laſt mentioned.

The ſixtieth and ſixtyfirſt Sorts were found in great Plenty at *Campechy* by the late Dr. *Houſtoun*, from whence he ſent their Seeds to *England*, where ſeveral of the Plants were raiſed. Theſe Plants have their lower Leaves narrow and entire; and thoſe which are produced near the upper Part of of the Shoots are broad and indented, ſomewhat like thoſe of the Garden *Orach*. The Flowers are produced at the Extremity of the Branches, which are of a greeniſh white, having little Beauty in them; and they ſoon fall off, ſo that the Plants rarely produce good Seeds in *England*.

Theſe Plants are propagated by Seeds, which ſhould be ſown on a Hot-bed early in the *Spring*; and when the Plants come up, they ſhould be each tranſplanted into a ſeparate Pot filled with freſh light Earth, and then plunged into the Hot-bed again, where they ſhould be ſhaded until they have taken new Root; after which time they ſhould be treated in the ſame Manner as the tender Sorts before-mentioned. And in *Winter*, if theſe are plunged into the Bark-bed in the Stove, the Plants may more certainly be maintained than if placed on Shelves in the dry Stove; but then they ſhould not have too much Water given them in *Winter*, leſt it rot them. With this Management the Plants may be preſerved two or three Years, in which time they will grow to the Height of ſeven or eight Feet, and produce many Branches.

The ten laſt mentioned Sorts are all of them annual Plants, ſo their Seeds ſhould be ſown early in the *Spring* on a moderate Hot-bed; and the Plants, when they are come up, muſt be planted into Pots, and plunged into a Hot-bed; for they are too tender to thrive in the open Air in this Country: So they muſt be continued in the Hot-bed, or, when they are pretty ſtrong, they may be removed into the Stove, where they will flower in *June* and *July*, and their Seeds will ripen ſoon after, which will ſcatter themſelves as ſoon as they are ripe, if they are not gathered; ſo that when the Plants are permitted to ſhed their Seeds, there will be a ſufficient Supply of young Plants come up, in whatever Pots ſtand near them, as alſo in the Tan, if it be not diſturbed. The firſt five of theſe Sorts grow uſually about two Feet high or more; the next three ſeldom riſe above a Foot high, and the two laſt trail on the Surface of the Ground, ſo that theſe make but an indifferent Appearance.

TOAD-FLAX; *vide* Linaria.

TOBACCO; *vide* Nicotiana.

TOMENTUM, is that ſoft, downy Subſtance, which grows on the Leaves of ſome Plants.

TORDYLIUM, Hartwort.

The *Characters* are;

It is an umbelliferous Plant, with a roſe-ſhap'd Flower, conſiſting of five unequal heart-faſhion'd Petals, which are placed circularly, and reſt on the Empalement, which afterward becomes an almoſt-round Fruit, compoſed of two flat Seeds, which eaſily caſt off their Covering, with a raiſed Border, which is commonly indented.

The *Species* are;

1. TORDYLIUM *maximum. Inſt. R. H.* The greateſt Hartwort.

2. TORDYLIUM *Narbonenſe minus. Inſt. R. H.* Small Hartwort of Narbonne.

3. TORDYLIUM *Apulum minimum. Col. P.* 4. 124. The ſmalleſt Hartwort of Apulia.

4. TORDYLIUM *minus, limbo granulato, Syriacum. Mor. Umb.* Small Hartwort of Syria, with a granulated Border.

5. TORDYLIUM *folio longo anguſto, flore albo magno, ſemine elegantiſſime & profundiſſime crenato albo. Boerh. Ind. alt.* Hartwort with a long narrow Leaf, a large white Flower, and a white Seed beautifully and deeply notch'd.

6. TORDYLIUM *orientale, Secacul Arabum dictum Rawolfio. Boerh. Ind. alt.* Eaſtern Hartwort, called by Rauwolf, Secacul of the Arabians.

7. TORDYLIUM *Luſitanicum, cicutæ folio, ſemine ſtriato. Inſt. R. H.* Portugal Hartwort, with a Hemlock-leaf, and a ſtreaked Seed.

8. TORDYLIUM *album, facio tordylii lutei Columnæ. Hort. Cath.* White Hartwort, with the Appearance of Columna's yellow Hartwort.

All theſe are annual Plants, which periſh ſoon after they have perfected their Seeds. The firſt Sort is found wild in ſeveral Parts *England*, and the ſecond Sort has been by ſome mentioned as an indigenous Plant of this Country; but I believe it is no where found wild, unleſs where the Seeds have been purpoſely ſcatter'd. Theſe Plants are preſerved in the Gardens of ſome Perſons, who are curious in Botany, but there is little Beauty in them.

They are propagated by Seeds, which ſhould be ſown in the *Autumn* ſoon after they are ripe; when the Plants will ſoon appear, and are very hardy, ſo that they require no farther Care, but to keep them clear from Weeds; and where they come up too cloſe together, they ſhould be thinned ſo as to leave them ſix Inches aſunder. In *June* following the Plants will flower, and their Seeds will ripen in *Auguſt*; which if permitted to ſcatter on the Ground, will produce a Supply of Plants without any Trouble. If the Seeds of theſe Plants are kept out of the Ground till *Spring*, they ſeldom ſucceed; for if any Plants are produced from the Seeds then ſown, they commonly periſh before they have perfected their Seeds; whereas thoſe which are ſown in *Autumn* do rarely fail. Theſe Plants will grow on any Soil or Situation, ſo may be put into any obſcure Part of the Garden.

TORMENTILLA, Tormentil.

The *Characters* are;

The Flower conſiſts of four Petals, which are placed orbicularly, and expand in form of a Roſe; out of whoſe one-leav'd Empalement (divided into ſeveral Segments, and ſhap'd like a Baſon) ariſes the Pointal, which afterward becomes an almoſt globular Fruit, in which many Seeds are gathered into a ſort of little Head, covered with the Empalement: to which Notes muſt be added, That there are commonly ſeven Leaves growing on the Top of the Foot-ſtalk.

The *Species* are;

1. TORMENTILLA *ſylveſtris. C. B. P.* Wild Tormentil, or Septfoil.

2. TORMENTILLA *radice repente. Inſt. R. H.* Creeping-rooted Tormentil.

3. TORMENTILLA *Alpina vulgaris major. C. B. P.* Greater Tormentil of the Alps.

4. TRRMENTILLA *Caſſubica major. Inſt. R. H.* Greater Tormentil, with deep cut Leaves.

5. TORMENTILLA *Caſſubica minor. Inſt. R. H.* Smaller Tormentil, with deep-cut Leaves.

The firſt Sort grows wild every-where on dry Paſtures, and on Commons in moſt Parts of *England*. The Roots of this Plant have been frequently uſed for Tanning of Leather, in Places where Oak-bark is very ſcarce. This Root is alſo much uſed in Medicine, and is accounted the beſt Aſtringent in the whole vegetable Kingdom.

The ſecond Sort is found in ſome particular Parts of *England* growing wild: the third Sort grows on the *Alps*, and the fourth and fifth Sorts grow in *Denmark*, *Sweden*, and ſome other Northern Countries; but are rarely preſerved, unleſs in ſome Botanic Gardens, for the ſake of Variety. It requires no Care to propagate theſe Plants, ſince, if their Seeds are ſown in almoſt any Soil or Situation, the Plants will come up and flouriſh without any other Care, but to prevent their being over-run with great Weeds.

TOXICODENDRON, [of τοξικὸν, *Poiſon*, and δένδρον, a *Tree*.] Poiſon-tree, *vulgo*.

The *Characters* are;

The Flower conſiſts of five Leaves, which are placed orbicularly, and expand in Form of a Roſe; out of whoſe Flower-cup riſes the Pointal, which afterwards becomes a roundiſh dry, and for the moſt part, furrowed Fruit, in which is contained one compreſs'd Seed.

The *Species* are;

1. TOXICODENDRON *triphyllum glabrum. Tourn.* Three-leav'd ſmooth Poiſon-tree.

2. TOXICODENDRON *triphyllum, folio ſinuato pubeſcente. Tourn.* Three-leav'd Poiſon-tree with a ſinuated hairy Leaf.

3. TOXICODENDRON *Carolinianum, foliis pinnatis, floribus minimis herbaceis.* Carolina Poiſon Aſh, *vulgo*.

4. TOXICODENDRON *rectum, foliis minoribus glabris. Hort. Elth.* Upright Poiſon-tree, with ſmaller ſmooth Leaves.

5. TOXICODENDRON *rectum pentaphyllum glabrum, foliis latioribus.* Smooth five-leav'd upright Poiſon-tree, with broader Leaves.

6. TOXICODENDRON *amplexicaule, foliis minoribus glabris. Hort. Elth.* Climbing Poiſon-tree, with ſmaller ſmooth Leaves.

7. TOXICODENDRON *foliis alatis, fructu rhomboide. Hort. Elth.* Poiſon-tree with winged Leaves, and a Fruit ſhap' like a Rhombus.

The two firſt Species were brought from *Virginia*, man Years ſince, where they grow in great Plenty, as it is probable they do in moſt other Northern Parts of *Americ* The firſt Sort ſeldom advances in Height, but the Branche trail upon the Ground, and ſend forth Roots, by which the propagate in great Plenty.

The ſecond Sort will grow upright, and make a Shrub about four or five Feet high, but rarely exceeds that in this Country. This may be propagated by Layers, and is equally as hardy as the former.

The third Sort was rais'd from Seeds, which were ſent from *Carolina* by Mr. *Catesby*. This is ſomewhat tenderer than either of the former, but will endure the Cold of our ordinary *Winters* very well, eſpecially if it be planted near the Shelter of other Trees.

The fourth Sort grows erect to the Height of five or ſix Feet: the Leaves of this Kind are much ſmaller, than thoſe of the common Poiſon-oak; but the Branches of this are flexible, ſo that it will never make a Shrub of any great Height or Strength.

The fifth Sort was found in *Maryland*, from whence the Seeds were ſent to *England*. This grows more upright than the former, and by the Appearance of the young Plants, ſeems to be a Shrub of much larger Growth.

The ſixth Sort is a Native of *Virginia*, from whence I received the Seeds: this puts out Roots from the Branches, which faſten themſelves to the Stems of Trees, or the Joints of Walls, by which the Branches are ſupported.

The ſeventh Sort is the ſame with the third, only differing in Sex; this being the Female, and the other the Male Tree. All the Sorts of *Toxicodendron* differ in Sex, the Male never producing any Fruit, having ſmall herbaceous Flowers, without any Embryo's.

The four laſt are hardy Plants, which will thrive in the open Air in this Country; but they love a moiſt Soil, and ſhould be planted under Trees in Wilderneſſes, where they will thrive very well, and endure the Cold better than where they have a more open Expoſure. They may be propagated by Seeds, or from Suckers, which ſome of the Sorts ſend forth in Plenty, or by laying down the Branches of thoſe Sorts which do not put forth Suckers; which in one Seaſon will be ſufficiently rooted to tranſplant; when they ſhould be planted, where they are deſigned to remain. The beſt Time to remove theſe Shrubs, is in *March*, becauſe then there will be no Danger of their ſuffering by Froſt.

The Wood of theſe Shrubs is accounted very poiſonous, either by the handling of it, or ſmelling it when it is burning. Mr. *Dudley* has given an Account of the poiſonous Quality of theſe Trees, in the *Philoſophical Tranſactions*, where he mentions a Neighbour of his in *New-England*, who was blind for ſeveral Days with handling the Wood; and another Gentleman of that County, who was ſitting by his Fire-ſide in *Winter*, in which was ſome of the Poiſon-tree burning, the Smoak of which ſwelled him for ſeveral Days. But he ſays it has this Effect only on particular Perſons; for his own Brother would handle and chew it, without any Harm; and that by the ſame Fire ſome Perſons ſhall be poiſoned, and others not the leaſt affected. This Poiſon is not mortal, but will go off itſelf in a few Days, like the Sting of a Bee; but the People generally apply Plantain-water, or Sallet-oil and Cream, to the Part affected.

When a Perſon is poiſoned by handling of this Wood, in a few Hours he feels an itching Pain, which provokes a Scratching, which is follow'd by an Inflammation and Swelling. Sometimes a Perſon has had his Legs poiſoned, which have run with Water. Some of the Inhabitants of *America* affirm, they can diſtinguiſh this Wood by the Touch in the Dark, from its extreme Coldneſs, which is like Ice. But what he mentions of this poiſonous Quality, is applicable to the ſeventh Sort here mention'd, which by his Deſcription agrees with this *Species*.

This Sort of Poiſon-tree is not only a Native of *America*, but grows plentifully on the Mountains in *Japan*, where it is called *Faſi No Ki*; and from this Tree they extract one Sort of their *Varniſh* or *Lacca*, which they uſe for Japanning their Utenſils. But this is not their beſt Kind of Varniſh, that being made of the Juice of another Tree, which is alſo very poiſonous, and nearly allied to this, and from which ſome Writers think it differs only by Culture.

The Juice of this Tree is milky, when it iſſues out of the wounded Part; but ſoon after it is expoſed to the Air, it turns black, and has a very ſtrong fœtid Scent, and is corroding. For I have obſerved, on cutting off a ſmall Branch from one of theſe Shrubs, that the Blade of the Knife has been changed black in a Moment's time, ſo far as the Juice had ſpread over it; which I could not get off without grinding the Knife.

As this Tree is very common in *Virginia*, *Carolina* and *New-England*, it would be well worth the Inhabitants Trial, to make this Varniſh.

TRACHELIUM, Throatwort.

The *Characters* are;

It hath a funnel-ſhap'd Flower, compoſed one Leaf, and cut into ſeveral Parts at the Top; whoſe Empalement afterward becomes a membranaceous Fruit often triangular, and divided into three Cells, which are full of ſmall Seeds.

The *Species* are;

1. TRACHELIUM *azureum umbelliferum. Pon. Bald.* Blue umbelliferous Throatwort.

2. TRACHELIUM *umbelliferum violaceum, foliis laciniatis. Inſt. R. H.* Throatwort with violet-coloured Flowers growing in Umbels, and jagged Leaves.

3. TRACHELIUM *villoſum, floribus confertim ex foliorum alis naſcentibus. Inſt. R. H.* Hairy Throatwort, with Flowers growing in Cluſters from the Wings of the Leaves.

4. TRACHELIUM *petræum, floribus in capitulum congeſtis. Inſt. R. H.* Rock Throatwort, with Flowers collected in Heads.

5. TRACHELIUM *minus Africanum, floribus violaceis, per caulem ſparſis. Inſt. R. H.* Smaller African Throatwort, with violet-coloured Flowers, growing thinly on the Stalks.

6. TRACHELIUM *Americanum, ſonchi folio, flore albo longiſſimo. Plum.* American Throatwort, with a ſow-thiſtle Leaf, and a very long white Flower.

The firſt Sort is preſerved in many curious Gardens for the Beauty of its Flowers, which continue a long time, and are ſucceeded by new Umbels on the Tops of the younger Shoots, ſo that the Plants continue in Beauty for ſome Months. This Plant is ſuppoſed to be a Native of ſome of the Iſlands in the *Archipelago*, from whence it was firſt brought to *Italy*, and hath been ſince ſpread to many Parts of *Europe*. It is hardy in reſpect to Cold, provided it has a proper Situation, which ſhould be in the Crevices of old Walls, where it will abide the Cold very well; when thoſe Plants which grow on warm Borders are frequently deſtroyed. This Plant has propagated itſelf by Seeds, on the Walls of ſome Gardens, where it has been planted; and thoſe Plants which have grown on the Walls continue, when thoſe which were in Pots, and preſerved with Care, have been intirely deſtroyed.

The ſecond Sort grows upon the Mountains of *Breſcia*, about the Mouths of Caves, between the hardeſt Rocks, ſo that it is very difficult to get out the Roots.

The third Sort grows on the Rocks in ſeveral Places in the *Levant*.

All theſe Sorts are propagated by Seeds, which ſhould be ſown ſoon after they are ripe; for if they are kept out of the Ground till the *Spring*, they ſeldom grow. Theſe Seeds ſhould be ſown in Pots filled with freſh undunged Earth, and placed in a ſhady Situation till the Beginning of *October*, when they may be removed into a more open Expoſure; where they may have as much Sun as poſſible, but be ſhelter'd from the cold Winds. When the Cold is ſevere, they ſhould be placed under a Hot-bed Frame, where they may enjoy as much free Air as poſſible in mild Weather; but they muſt be ſcreened from hard Froſts, otherwiſe they are frequently deſtroyed.

They may alſo be propagated by Off-ſets, or Cuttings, which may be taken off in the *Spring* or *Summer* Months; and ſhould be planted in Pots filled with freſh undunged Soil, and placed in a ſhady Situation until they have taken Root, when they may be removed into a ſheltered Part of the Garden; where being mix'd with other hardy exotic Plants, they will afford an agreeable Variety.

But as theſe Plants thrive better on old Walls, (when by Accident they have ariſen there from Seeds) ſo their Seeds, when ripe, may be ſcattered on ſuch Walls as are old, or where there is Earth lodged ſufficient to receive the Seeds; where the Plants will reſiſt the Cold much better, and they will continue longer, than when ſown in the full Ground; and when a few of the Plants are eſtabliſhed on the Walls, they will ſhed their Seeds, ſo that they will maintain themſelves without any farther Care. I have obſerved ſome Plants of the firſt Kind, which have grown from the Joints of a Wall, where there has not been the leaſt Earth to ſupport them; which have reſiſted the Cold, tho' they have been greatly expoſed to the Winds; ſo that theſe Plants are very proper to cover the Walls of Ruins, where they will have a very good Effect.

The fourth Sort grows on the Mountains in *Italy*, from between the Crevices of the Rocks, from whence it is difficult to get out the Roots. This may be treated in the ſame manner as the former Sorts, and will thrive better on Walls, than if ſown or planted in the Earth.

The fifth Sort is an annual Plant, which was brought from the *Cape of Good Hope* to *Holland*, where it has been preſerved in ſome of their curious Botanic Gardens. This Sort will ſucceed well, if the Seeds are permitted to ſcatter on the Pots of Earth which are near them; provided the Pots are placed in the Green-houſe, where the Plants will come up and flower early the following *Summer*, and will have Time to perfect their Seeds; whereas, when the Seeds are ſown in the *Spring*, the Plants will not flower till *Auguſt*; ſo that, if the *Autumn* ſhould prove bad; they will not produce Seeds.

The ſixth Sort grows plentifully in *Jamaica* and ſeveral other Places in the warm Parts of *America*, where it grows in moiſt Places by the Sides of Rivers. This may be propagated by Seeds, which ſhould be ſown early in the *Spring* on a moderate Hot-bed; and when the Plants are come up, they ſhould be tranſplanted on another Hot-bed, to bring the Plants forward; and then they may be treated in the ſame manner as hath been directed for the tender Sorts of *Rapuntium*. With which Management this Plant will thrive, and produce its Flowers; and if the Seeds are permitted to ſcatter, or are ſown as ſoon as they are ripe, if the Pots are kept in the Stove, the Plants will come up, and flouriſh much better than thoſe ſown in the *Spring*.

TRAGACANTHA, [τραγάκανθα of τράγος, a *Goat*, and ἀκάνθη a *Thorn*.] Goats thorn.

The *Characters* are;

It hath a papilionaceous Flower, out of whoſe Empalement ariſes the Pointal, which afterwards becomes a bicapſular Pod, fill'd with Kidney-ſhap'd Seeds. To theſe Notes muſt be added, The Leaves grow by Pairs on a middle Rib, which always ends in a Thorn.

The *Species* are;

1. TRAGACANTHA *Maſſilienſis. J. B.* Goats-thorn of Marſeilles.

2. TRAGACANTHA *Cretica incana, flore parvo, lineis purpureis ſtriato. T. Cor.* Hoary Goats-thorn of Crete, with a ſmall Flower ſtrip'd with purple Lines.

3. TRAGACANTHA *humilis Balearica, foliis parvis vix incanis, flore albo. Salvad.* Low Balearic Goats-thorn, with ſmall Leaves and a white Flower.

4. TRAGACANTHA *altera, Poterium fortè Cluſio. J. B.* Another Goats-thorn, with Leaves falling off in the Winter.

5. TRAGACANTHA *Alpina ſempervirens, floribus purpuraſcentibus. Inſt. R. H.* Ever-green Alpine Goats-thorn, with purpliſh Flowers.

6. TRAGACANTHA *Cretica, foliis minimis incanis, flore majore albo. Tourn. Cor.* Goats-thorn of Candy, with very ſmall hoary Leaves, and a larger white Flower.

7. TRAGACANTHA *orientalis humillima, flore magno albo. Tourn. Cor.* A very low eaſtern Goats-thorn, with a large white Flower.

8. TRAGACANTHA *orientalis humillima, barbæ Jovis folio. Tourn. Cor.* A very low eaſtern Goats-thorn, with a Jupiter's-beard Leaf.

9. TRAGACANTHA *orientalis humillima, foliis anguſtiſſimis argenteis. Tourn. Cor.* A very low eaſtern Goats-thorn, with very narrow ſilver Leaves.

10. TRAGACANTHA *orientalis humillima, ſe ſpargens, floribus ſpicatis. Tourn. Cor.* A very low ſpreading eaſtern Goats-thorn, with Flowers growing in Spikes.

11. TRAGACANTHA *orientalis humillima incana, flore purpuraſcente. Tourn. Cor.*, A very low hoary eaſtern Goats-thorn, with a purpliſh Flower.

12. TRAGACANTHA *orientalis erectior, foliis viciæ glabris, & ramis tomentoſis. Tourn. Cor.* A more upright eaſtern Goats-thorn, with ſmooth vetch Leaves, and woolly Branches.

13. TRAGACANTHA *orientalis humilis, candidiſſima & tomentoſa, floribus in foliorum alis in capitulum denſum naſcentibus. Tourn. Cor.* A lower very white and woolly eaſtern Goats-thorn, with Flowers growing in thick Heads, from the Wings of the Leaves.

14. TRAGACANTHA *orientalis humilis, floribus luteis denſè congeſtis in foliorum alis. Tourn. Cor.* A low eaſtern Goats-thorn, with yellow Flowers thick-ſet in the Wings of the Leaves.

15. TRAGACANTHA *humilior, luteis floribus. C. B. P.* A lower Goats-thorn, with yellow Flowers.

16. TRAGACANTHA *orientalis, floribus luteis in capitulum longo pediculo donatum congeſtis. Tourn. Cor.* Eaſtern Goats-thorn, with yellow Flowers gathered into a Head, on a long Foot-ſtalk.

17. TRAGACANTHA *orientalis veſicaria, floribus purpureis in capitulum longo pediculo donatum congeſtis. Tourn. Cor.* Bladder eaſtern Goats-thorn, with purple Flowers gathered into a Head, and ſet on a long Foot-ſtalk.

18. TRAGACANTHA *orientalis latifolia, flore purpureo magno. Tourn. Cor.* Eaſtern Goats-thorn, with a large purple Flower.

19. TRAGACANTHA *orientalis, foliis anguſtiſſimis, flore purpuraſcente. Tourn. Cor.* Eaſtern Goats-thorn, with very narrow Leaves, and a purpliſh Flower.

20. TRAGACANTHA *orientalis, foliis oleæ, humillima, floribus in capitulum congeſtis. Tourn. Cor.* A very low eaſtern Goats-thorn, with olive Leaves, and Flowers gathered into a Head.

21. TRAGACANTHA *orientalis, foliis oleæ, incanis & tomentoſis, caule ab imo ad ſummum florido. Tourn. Cor.* Eaſtern Goats-thorn, with hoary and woolly olive Leaves, and Flowers growing from the Bottom to the Top of the Stalks.

22. TRAGACANTHA *orientalis, foliis incanis, caule & ramulis tomentoſis. Tourn. Cor.* Eaſtern Goats-thorn, with hoary Leaves, and woolly Stalks and Branches.

23. TRAGACANTHA *foliis incanis minoribus, minuſque villoſis. Boerh. Ind. alt.* Goats-thorn with ſmaller hoary Leaves, which are leſs hairy.

Moſt of theſe Plants grow wild in the Iſlands of the *Archipelago*; but the three firſt are all the Sorts I have yet ſeen cultivated in the *Engliſh* Gardens.

Theſe Plants may be propagated either from Seeds or by Cuttings, but as they rarely produce Seeds in this Country, ſo the latter Method is only uſed here. The beſt time for this Work is in *April*, juſt as the Plants begin to ſhoot; at which time the tender Branches of the Plants ſhould be taken off, and their lower Parts diveſted of the decay'd Leaves; then they ſhould be planted on a very moderate Hot-bed, which ſhould be cover'd with Mats, to ſcreen them from the great Heat of the Sun by Day, and the Cold by Night: Theſe Cuttings ſhould be frequently water'd until they have taken Root; after which they may be expos'd to the open Air, obſerving always to keep them clear from Weeds, and in very dry Weather they muſt be refreſh'd with Water.

On this Bed they may remain until the following *Spring*, where, if the *Winter* ſhould be very ſevere, they may be cover'd with Mats, as before, and in *April* they may be tranſplanted out either into Pots filled with ſandy, light Earth, or into warm Borders, where, if the Soil be dry, gravelly, and poor, they will endure the ſevereſt Cold of our Climate; but if they are planted in a very rich Soil, they often decay in *Winter*.

From the ſecond Sort Monſieur *Tournefort* ſays, the Gum *Adragant* or *Dragon* is produc'd in *Crete*, of which he gives the following Relation in his Voyage to the *Levant*: “We
“ had the Satisfaction of fully obſerving the Gum *Adragant*
“ on Mount *Ida*. I cannot underſtand how *Bellonius* comes
“ to aſſert ſo poſitively, that there is no ſuch thing in *Can-*
“ *dia*: Sure he had not read the firſt Chapter of the ninth
“ Book of *Theophraſtus*'s Hiſtory of Plants. The little *bald*
“ *Hillocks* about the *Sheepfold* produce much of the *Traga-*
“ *cantha*, and that too a very good Sort. *Bellonius* and
“ *Proſper Alpinus* were doubtleſs acquainted with it; tho' it
“ is hardly poſſible, from their Deſcriptions, to diſtinguiſh
“ it from the other Kinds they make mention of. This
“ Shrub ſpontaneouſly yields the Gum *Adragant* towards
“ the End of *June*, and in the following Months; at which
“ time, the nutritious Juice of this Plant, thicken'd by the
“ Heat, burſts open moſt of the Veſſels wherein it is con-
“ tain'd. It is not only gather'd in the Heart of the Trunk
“ and Branches, but alſo in the Inter-ſpaces of the Fibres,
“ which are ſpread in the Figure of a Circle like Rays of the
“ Sun. This Juice is coagulated into ſmall Threads, which
“ paſſing through the Bark, iſſue out by little and little, ac-
“ cording as they are protruded by the freſh Supplies of Juice
“ ariſing from the Roots. This Subſtance being expos'd to
“ the Air, grows hard, and is formed either into Lumps, or
“ ſlender Pieces, curled and winding in the Nature of
“ Worms, more or leſs long, according as Matter offers. It
“ ſeems as if the Contraction of the Fibres of this Plant
“ contributes to the expreſſing of the Gum. Theſe delicate
“ Fibres, as fine as Flax, being uncover'd and trodden by
“ the Feet of the Shepherds and Horſes, are by the Heat
“ ſhrivelled up, and facilitate the Emanation of the extra-
“ vaſated Juices.

But notwithſtanding what *Tournefort* has ſaid concerning the Gum *Adragant* being produced from that particular Species, many Authors are of Opinion, that it is taken from from ſeveral other Species, but particularly that of *Marſeilles*,

ſeilles, from whence that Gum is often brought into *England.*

The laſt twenty Sorts were moſt of them diſcovered by Dr. *Tournefort* in the *Levant*, from whence he ſent the Seeds of ſeveral Kinds to the Royal Garden at *Paris*.

They may be propagated by Seeds, which ſhould be ſown on a Bed of freſh Earth in *March*; and when the Plants come up, they ſhould be carefully kept clean from Weeds; which, if permitted to grow amongſt the Plants, would ſoon over-bear and deſtroy them, while they are young. If the Seaſon ſhould prove very dry, it will be of great Service to water the Plants now and then; and when they are large enough to tranſplant, they ſhould be carefully taken up, and ſome of them planted into ſmall Pots filled with freſh Earth, placing them in the Shade until they have taken Root; after which Time they may be removed into an open Situation, where they may remain till the latter end of *October*; when they ſhould be placed under a common Frame, where they may be ſhelter'd from ſevere Froſt, but may have free Air in mild Weather; when the Glaſſes ſhould not be put over them.

The remainder of the Plants may be planted on a warm dry Border, where they muſt be ſhaded until they take Root; and if the Seaſon ſhould continue dry, they muſt be refreſh'd with Water, otherwiſe they will be in Danger; becauſe, while they are ſo young, their Roots will not have eſtabliſhed themſelves in the Ground, ſufficiently to nouriſh them in great Droughts.

Thoſe Plants which are planted in Pots may be preſerved for a Year or two under Frames in *Winter*, until they have obtained Strength, when they may be ſhaken out of the Pots, and planted in a lean dry Soil, and a warm Situation, where they will endure the Cold of our ordinary *Winters* very well; but as they are ſometimes deſtroyed by hard *Winters*, ſo it will be proper to keep a Plant of each Kind in Pots, which may be ſheltered in *Winter* to preſerve the *Species*.

Theſe Plants may alſo be propagated by Cuttings, which may be planted during the *Summer* Months, in the manner above directed.

The *Gum Dragon* which is uſed in the Shops, is produced from ſeveral of theſe Species; tho' it was only from the ſecond Sort which Dr. *Tournefort* ſaw it taken.

At preſent theſe Plants are rarely preſerved, excepting by ſome Perſons who are curious in Botany; yet in large Gardens many of them deſerve a Place, where, if they are planted on Hillocks, or the Slopes of dry Banks, they will have a very good Effect, eſpecially as they retain their Leaves thro' the Year.

TRAGIA.

The *Characters* are;

It hath a funnel-ſhap'd Flower, conſiſting of one Leaf, for the moſt part divided into three Segments, but theſe are barren; for the Embryos are placed at a Diſtance on the ſame Plant, which afterward becomes a tricoceos Fruit, compoſed of three Cells, each containing one ſpherical Seed.

The *Species* are;

1. Tragia *alia ſcandens, urticæ folio. Plum. Nov. Gen.* Climbing Tragia, with a Nettle-leaf.

2. Tragia *ſcandens, longo betonicæ folio. Plum. Nov. Gen.* Climbing Tragia, with a Betony-leaf.

Theſe Plants were diſcovered by Father *Plumier* in *America*, who conſtituted this Genus by this Name, in Honour to *Hieronymus Bock*, a famous Botaniſt, who was commonly called *Tragus*.

The firſt Sort grows plentifully in the *Savannahs* in *Jamaica*, and the other warm Parts of *America*; where it twines round whatever Plants or Trees it grows near, and riſes ſeven or eight Feet high, having tough woody Stems. The Leaves are like thoſe of the common Nettle, and the whole Plant is covered with burning Spines, like thoſe of the Nettle; which renders it very unpleaſant to handle.

The ſecond Sort was found by the late Dr. *Houſtoun* at *Campechy*, from whence he ſent the Seeds.

As theſe are Plants of no Beauty, ſo they are ſeldom preſerved in this Country, except in ſome Botanic Gardens, for the ſake of Variety. They are propagated by Seeds, which muſt be ſown on a Hot-bed early in the *Spring*, and muſt afterwards be tranſplanted into Pots, and plunged into a Hot-bed of Tanners-bark, and treated in the ſame manner as the *Dioſcorea*; with which Management theſe Plants will thrive very well.

TRAGOPOGON, [τραγοπώγων, of τράγος, a *Goat*, and πώγων, a *Beard*, becauſe the pappous Seed, while it is included in the *Calyx*, reſembles the Beard of a Goat] Goats-beard.

The *Characters* are;

It is a Plant with a ſemifloſculous Flower, conſiſting of many half Florets; theſe, with the Embryo's, are included in one common many-leav'd Flower-cup, which is not ſcaly, as in Scorzonera, *but the Segments are ſtretch'd out above the Florets, the Embryo's afterwards become oblong Seeds incloſ'd in Covers or Coats, and have a thick Down like a Beard adhering to them.*

The *Species* are;

1. Tragopogon *pratenſe luteum majus. C. B. P.* Greater Meadow Goats-beard, with a yellow Flower, *commonly called* Go-to-Bed-at-Noon.

2. Tragopogon *purpureo-cæruleum, porri folio, quod Artiſi, vulgo. C. B. P.* Goats-beard, with a Leaf like Leeks, and a purple blue Flower, *commonly called* Salſaffy *or* Saſſafy.

3. Tragopogon *alter, gramineo folio, ſuave-rubens. Col.* Another Goats-beard, with a graſſy Leaf and ſoft red Flowers.

There are ſeveral other Species of this Plant, which are preſerved in ſome curious Botanick Gardens for the Sake of Variety; but as they are not cultivated for Uſe, ſo I ſhall omit enumerating them in this Place.

The firſt Sort here mentioned grows wild in moiſt Meadows in divers Parts of *England*; and in *May*, when the Stems begin to advance, they are by many People gather'd to boil, and are by ſome preferr'd to *Aſparagus*.

The ſecond Sort was formerly more in Eſteem than at preſent: This was brought from *Italy*, and cultivated in Gardens for Kitchen Uſe, the Roots being by ſome People greatly valued; but of late there is but little cultivated for the Markets, tho' ſeveral Gentlemen preſerve it in Gardens to ſupply their Tables.

The third Sort is by ſome preſerved for the Variety of its Flowers.

Theſe Plants are propagated from Seeds, which ſhould be ſown in the *Spring* upon an open Spot of Ground, in Rows about nine or ten Inches diſtant; and when the Plants are come up, they ſhould be houghed out, leaving them about ſix Inches aſunder in the Rows: the Weeds ſhould alſo be carefully houghed down as they are produc'd, otherwiſe they will ſoon over-bear the Plants, and ſpoil them. This is the only Culture they require; and if the Soil be light, and not too dry, they will make large Plants before *Winter*; at which time the *Salſaffy*, whoſe Roots are moſt commonly uſed, will be fit for Uſe, and may be taken up any time after their Leaves are decay'd; but when they begin to ſhoot again, they will be ſticky, and not fit for Uſe; but many Perſons do cultivate this Sort for the Shoots, which they boil and eat after the manner of Aſparagus; for this Sort producing ſtrong Shoots, is more valuable than the yellow Sort.

The common yellow Sort, whoſe Shoots are preferr'd, will be fit for Uſe in *April* or *May*, according to the Forwardneſs of the Seaſon: The beſt time to cut them is, when their Stems are about four Inches long; for if they ſtand too long, they are never ſo tender as thoſe which are cut while young.

Some People in cultivating theſe Plants, ſow their Seeds in Beds pretty cloſe, and when the Plants come up, they tranſplant them out in Rows at the before-mentioned Diſtance; but as they do always form a Tap-root, which abounds with a milky Juice, ſo when the extreme Part of their Roots is broken by tranſplanting, they do ſeldom thrive well afterward; therefore it is by far the better Way to make ſhallow Drills in the Ground, and ſcatter the Seeds therein, as before directed, whereby the Rows will be at a due Diſtance, and there will be nothing more to do than to hough out the Plants when they are too thick in the Rows, which will be much leſs Trouble than the other Method of tranſplanting, and the Plants will be much larger and fairer.

TRAGOSELINUM, Burnet-ſaxifrage.

The *Characters* are;

It hath an umbellated Roſe-ſhaped Flower, compoſed of five unequal Heart-ſhaped Petals, which are placed circularly, and reſt on the Empalement; which afterward becomes a Fruit, compoſed of two oblong ſtreaked Seeds.

The *Species* are;

1. **Tragoselinum** *majus, umbellâ candidâ. Inſt. R. H.* Greater Burnet-ſaxifrage, with a white Umbel.

2. **Tragoselinum** *majus, umbellâ rubente. Inſt. R. H.* Greater Burnet-ſaxifrage, with a red Umbel.

3. **Tragoselinum** *alterum minus. Inſt. R. H.* Leſſer round-leaved Burnet-ſaxifrage.

4. **Tragoselinum** *minus. Inſt. R. H.* Small Burnet-ſaxifrage.

5. **Tragoselinum** *radice nigrâ, Germanicum. Jeſſieu.* German Burnet-ſaxifrage, with a black Root.

6. **Tragoselinum** *Auſtriacum, foliis profundiſſimè inciſis, Boerh.* Auſtrian Burnet-ſaxifrage, with Leaves very deeply cut.

7. **Tragoselinum** *Creticum maximum villoſum, flore albo. Tourn. Cor.* The greateſt hairy Burnet-ſaxifrage of Crete, with a white Flower.

8. **Tragoselinum** *minus ſaxatile fœtidiſſimum, apii folio. Tourn. Cor.* The leaſt ſtinking Rock Burnet-ſaxifrage, with a ſmallage Leaf.

9. **Tragoselinum** *Orientale laciniatum, umbellâ purpuraſcente. Tourn. Cor.* Eaſtern Burnet-ſaxifrage, with cut Leaves, and a purpliſh Flower.

10. **Tragoselinum** *Orientale laciniatum, umbellâ albâ. Tourn. Cor.* Eaſtern cut-leaved Burnet-ſaxifrage, with a white Umbel.

The firſt Sort is directed by the College of Phyſicians to be uſed in Medicine; but many times the Herb Women in the Markets impoſe on ignorant Perſons two Herbs for this one, *viz. Burnet*, and *Meadow-ſaxifrage*; which they ſell for *Burnet-ſaxifrage*, which are two very different Plants, and of contrary Qualities. This Sort grows wild on the dry ſhady Banks in *Kent*, and in ſeveral other Parts of *England*.

The ſecond Sort is a Variety of the firſt, from which it only differs in the Colour of the Flowers, which in this Sort are red, and the other are white.

The third Sort grows wild in ſome Parts of *England*, but is not ſo common as the fourth, which is the moſt common Sort in the Fields near *London*. This fourth Sort is ſometimes brought to the Markets, and may be uſed inſtead of the firſt; though it is much better to have the particular Sort ordered by the College, when it can be procured.

All the other Sorts are Strangers in this Country, but are often preſerved by the curious Botaniſts in their Gardens for Variety, and are all of them as hardy as the common Sorts.

Theſe Plants are propagated by Seeds, which ſhould be ſown on a ſhady Border of freſh Earth at *Michaelmas*; for if they are ſown in the *Spring* they frequently miſcarry, as do many of the umbelliferous Plants. In the *Spring* following the Plants will appear, when they ſhould be carefully clear'd from Weeds; and as the Plants obtain Strength, ſo they ſhould be thinned where they grow too cloſe; leaving them five or ſix Inches apart. After this they will require no other Culture, but to keep them clear from Weeds. The ſecond *Summer* theſe Plants will flower, and produce Seeds; but if the Roots are not diſturbed, they will continue ſeveral Years, and produce Seeds annually. Therefore, where the Plants are deſigned to remain, the Seeds ſhould be ſown in Drills, at about fixteen Inches apart, which will allow Room to dig the Ground between the Rows every *Winter*; whereby the Roots will be greatly encouraged, and the Weeds will be better deſtroyed.

TRANSPLANTING of TREES; *vide* Planting.

TRANSPORTATION of PLANTS: In ſending Plants from one Country to another, great Regard ſhould be had to the proper Seaſon for doing it: For Example, if a Parcel of Plants are to be ſent from a hot Country to a cold one, they ſhould be ſent in the *Spring* of the Year, that as they come towards the colder Parts, the Seaſon may be advancing, and hereby, if they have ſuffered a little in their Paſſage, there will be Time to recover them before *Winter*; whereas thoſe which arrive in *Autumn* are often loſt in *Winter*, becauſe they have not Time to recover and get Root before the Cold comes on.

On the contrary, thoſe Plants which are ſent from a cold Country to a hot one, ſhould always be ſent in *Winter*, that they may arrive time enough to be rooted before the great Heats come on, otherwiſe they will ſoon periſh.

The beſt Way to pack up Plants for a Voyage (if they are ſuch as will not bear to be kept out of the Ground) is, to have ſome handy Boxes with Handles to them, for the more eaſily removing them in bad Weather: Theſe ſhould have Holes bored in their Bottoms to let out the Moiſture, otherwiſe it will rot the Roots of the Plants. Over each of theſe Holes ſhould be laid a flat Tile or Oyſter Shell, to prevent the Earth from ſtopping them; then they ſhould be filled up with Earth, into which the Plants ſhould be ſet as cloſe as poſſible to each other, in order to ſave Room (which is abſolutely neceſſary, otherwiſe they will be very troubleſome in the Ship); and as the only Thing intended is, to preſerve them alive, and not to make any Progreſs while on their Paſſage, ſo a ſmall Box will contain many Plants, if rightly planted. The Plants ſhould alſo be placed in the Box a Fortnight or three Weeks before they are put on board the Ship, that they may be a little ſettled and rooted; and during the Time they are on board, they ſhould remain, if poſſible, on the Deck, that they may have Air: but in bad Weather they ſhould be covered with a Tarpawlin, to guard them againſt the ſalt Water, which will deſtroy them if it comes at them in any Quantity.

The Water theſe Plants ſhould have, while on board, muſt be proportioned to the Climate where they come from, and to which they are going: If they come from a hot Country to a cold one, then they ſhould have very little Moiſture, after they have paſſed the Heats; but if they are carry'd from a cold Country to a hot one, they muſt have a greater Share of Moiſture when they come into a warmer Climate, and ſhould be ſhaded in the Day from the violent Heat of the Sun, to which, if they are too much expoſed, it will dry them up and deſtroy them.

But if the Plants to be ſent from one Country to another, are ſuch as will live out of the Ground a conſiderable Time, as all thoſe which are full of Juice will do; as the *Sedums, Ficoides, Euphorbiums, Cereus's*, &c. then they require no other Care but to pack them up in a cloſe Box, wrapping them up well with Moſs, obſerving to place them ſo cloſely that they may not be tumbled about, which will bruiſe them, and that thoſe Plants which have Spines may not wound any of the others. The Box alſo ſhould be placed where they may receive no Moiſture, and where Rats cannot come to them, otherwiſe they are in Danger of being eaten by thoſe Vermin; but if theſe Plants are packed too cloſe, they are apt to ferment, and thereby either rot, or at leaſt grow ſickly; to prevent which they ſhould have a good Quantity of dry Hay or Straw laid between them, and ſeveral ſmall Holes ſhould be made in the Boxes, to let out the noxious Air.

If theſe Plants are thus carefully packed up, they will do well, tho' they ſhould be two, three, or ſome Sorts, if they are four or five Months on their Paſſage, and will be leſs liable to ſuffer than if planted in Earth, becauſe the Sailors generally kill theſe Plants by over-watering them.

There are alſo ſeveral Sorts of Trees which may be packed up in Cheſts with Moſs about them, which will bear to be kept out of the Ground two or three Months, provided it be at a Seaſon when they do not grow; as may be ſeen by the *Orange-trees, Jaſmines, Capers, Olive* and *Pomegranate-trees*, which are annually brought from *Italy*, and if ſkilfully managed, very few of them miſcarry, notwithſtanding they are many times kept three or four Months out of the Ground.

In ſending Seeds from one Country to another, the great Care to be taken is, to ſecure them from Vermin, and preſerve them dry, otherwiſe they mould and decay. The Method Mr. *Cateſby* always obſerved, was, to put up his Seeds dry into Papers, and then put them into a dry Gourd Shell, and ſeal them up; in which Way he ſent ſeveral large Parcels of Seeds from *Carolina* to *England*, which never miſcarried. There are ſome Perſons who have directed to put them into Glaſſes, and to ſeal them cloſely down, to keep out the external Air; but from ſeveral Experiments of this Kind which I have made, I find Seeds thus cloſely put up will not grow, if they remain ſtopped up any conſiderable Time, all Seeds requiring ſome Share of Air, to preſerve their vegetating Quality: So that where a Perſon has no other Conveniency, they may be put up in a Bag, and hung up in a dry Part of the Ship, or put into a Trunk, where they may be ſafe from Vermin; in which Places they will keep very well.

N. B. It is the ſafeſt Way to bring all Sorts of Seeds in their Pods or Huſks in which they grew, provided they are put up dry, becauſe their own Covering will afford them ſome Nouriſhment if the Seeds are not ſeparated from the *Placenta*.

TRIBULUS, Caltrops.

The *Characters* are;

It hath a Flower compoſed of ſeveral Leaves, which are placed circularly, and expand in form of a Roſe; out of whoſe Em-

Empalement riſes the Pointal, which afterward becomes a turbinated Fruit, compoſed of ſeveral Parts, which have Thorns, collected into a Head, and having ſeveral Cells, in which are incloſed oblong Seeds.

The *Species* are;

1. TRIBULUS *terreſtris, ciceris folio, fructu aculeato. C. B. P.* Land-caltrop, with a Chich Leaf, and a prickly Fruit.

2. TRIBULUS *terreſtris major Curaſſavicus. Prod. Par. Bat.* Greater Land American Caltrops.

3. TRIBULUS *terreſtris Americanus, fructu turbinato, foliis lanuginoſis. Plum. Cat.* American Land-caltrops, with a turbinated Fruit, and downy Leaves.

4. TRIBULUS *terreſtris Indiæ orientalis, foliis viciæ ſubrotundis & villoſis. Inſt. R. H.* Eaſt-India Land-caltrops, with roundiſh and hairy Vetch Leaves.

The firſt Sort is a very common Weed in the South of *France*, in *Spain* and *Italy*, where it grows amongſt Corn, and on moſt of the arable Land, and is very troubleſome to the Feet of Cattle; for the Fruit, being armed with ſtrong Prickles, run into the Feet of the Cattle which walk over the Land. This is certainly the Plant which is mentioned in *Virgil's Georgics*, under the Name of *Tribulus*, tho' moſt of his Commentators have applied it to other Plants.

It is called in *Engliſh*, *Caltrops*, from the Form of the Fruit, which reſembles thoſe Inſtruments of War that were caſt in the Enemies Way to annoy their Horſes.

This Plant is preſerved in ſeveral curious Gardens in *England*, for the ſake of Variety. It is propagated by Seeds, which ſhould be ſown in the *Autumn*; for thoſe which are kept out of the Ground till *Spring*, commonly remain in the Ground a whole Year before the Plants come up. Theſe Seeds ſhould be ſown on an open Bed of freſh light Earth, where they are deſigned to remain; for, as it is an annual Plant, ſo it doth not bear tranſplanting very well, unleſs it be done when the Plants are very young. In the *Spring*, when the Plants come up, they ſhould be carefully cleared from Weeds; and where they come up too cloſe, ſome of the Plants ſhould be pulled out, to give Room for the remaining Plants to grow. After this they will require no other Culture, but to keep them clear from Weeds. In *June* they will begin to flower, and their Seeds will ripen in *Auguſt* and *September*; which if permitted to ſcatter, the Plants will come up the following *Spring*, and maintain their Place, if they are not over-born with larger Weeds.

The Branches of this Plant trail on the Ground, and when the Plants are vigorous, will ſpread to a great Diſtance from the Root; the Flowers come out on long Foot-ſtalks from the Diviſion of the Branches, which are ſucceeded by the Fruit. Theſe, when they are ripe, divide into ſeveral Parts: ſo that if they are not gathered they will ſoon drop off.

The other three Sorts, being Natives of hot Countries, are very tender, ſo muſt be ſown on a Hot-bed early in the *Spring*; and when the Plants are come up, they muſt be each tranſplanted into a ſeparate Pot, filled with rich light Earth, and then plunged into a Hot-bed of Tanners-bark, where they muſt be treated in the ſame Manner as other tender exotick Plants; being careful to bring them forward as early as poſſible in the *Summer*, otherwiſe they will not perfect their Seeds in this Country.

Theſe are all of them annual Plants, whoſe Branches trail on the Ground, in the ſame Manner as the common Sort; but when their Roots are pretty much confined in the Pots, they will not grow ſo vigorous as when planted in larger Pots; ſo will flower and fruit much earlier in the Seaſon. The ſecond Sort produces large yellow Flowers, which have an agreeable Scent.

TRICHOMANES, Maiden-hair.

There are three or four Varieties of this Plant which grow in *Europe*; but in *America* there are a great Number of Species, which are remarkably different from each other, as alſo from the *European* Kinds.

Theſe being of the Tribe of *Ferns*, are ſeldom preſerved in Gardens, but where any Perſon is curious to collect them. Their Roots ſhould be planted in moiſt ſhady Places, eſpecially the *European* Sorts, which commonly grow from between the Joints of old Walls, about Wells, and in other very moiſt ſhady Situations. But thoſe Sorts which are brought from hot Countries, muſt be planted in Pots filled with Rubbiſh, and ſtrong Earth mixed; and in *Winter* they muſt be ſcreened from hard Froſts, to which if they are expoſed it will deſtroy them.

The common Sort in *England* is generally ſold in the Markets for the true *Maiden-hair*, which is a very different Plant, and not to be found in *England*, it being a Native of the South of *France*, and other warm Countries; ſo is rarely brought to *England*.

TRIFOLIUM, [of *tres*, *three*, and *folium*, Lat. a *Leaf*.] Trefoil.

The *Characters* are:

It hath a papilionaceous Flower, or reſembles a papilionaceous Flower, for it conſiſts of the Standard; the Wings and the Keel coming out of the Empalement, together with the Pointal, cover'd with its fringed Sheath; it becomes a Capſule, hidden in the Empalement, and full of Seeds, which are for the moſt part ſhaped like a Kidney, adhering cloſe to the Capſule when ripe. Some of this Genus have Flowers conſiſting of one Leaf, reſembling a papilionaceous Flower, out of whoſe Empalement ariſes the Pointal, which afterward becomes a membranaceous Capſule hidden in the Empalement, and filled with Kidney-ſhaped Seeds. To theſe Notes muſt be added, Leaves growing by Threes, ſeldom by Fours or Fives, on a common Foot-ſtalk.

The *Species* are;

1. TRIFOLIUM *purpureum majus ſativum, pratenſi ſimile. Raii Syn.* Greater purple manured Trefoil, *commonly called* Clover.

2. TRIFOLIUM *pratenſe purpureum vulgare. Mor. Hiſt.* Common Meadow Trefoil, with a purple Flower, *commonly called* Honey-ſuckle Trefoil.

3. TRIFOLIUM *pratenſe album. C. B. P.* White Meadow Trefoil.

4. TRIFOLIUM *arvenſe humile ſpicatum, ſive Lagopus. C. B. P.* Hare's-foot Trefoil.

5. TRIFOLIUM *fragiferum. Ger. Emac.* Strawberry Trefoil.

6. TRIFOLIUM *pratenſe luteum, capitulo lupuli, vel agrarium. C. B. P.* Hop Trefoil.

7. TRIFOLIUM *bitumen redolens. C. B. P.* Trefoil, ſmelling of Bitumen.

8. TRIFOLIUM *bitumen redolens, anguſtifolium. Boerh. Ind.* Narrow-leav'd Trefoil, ſmelling of Bitumen.

9. TRIFOLIUM *Africanum fruticans, flore purpuraſcente. H. Amſt.* African ſhrubby Trefoil, with a purpliſh Flower.

10. TRIFOLIUM *purpureum majus, foliis longioribus & anguſtioribus, floribus ſaturatioribus. Raii Syn.* The greater purple Trefoil, with longer and narrower Leaves and deeper coloured Flowers.

11. TRIFOLIUM *pratenſe folliculatum. C. B. P.* Bladder Meadow-trefoil.

12. TRIFOLIUM *luteum lupulinum minimum. Mor. Hiſt.* The leaſt yellow Hop-trefoil.

13. TRIFOLIUM *montanum, ſpicâ longiſſimâ rubente. C. B. P.* Mountain-trefoil, with a very long reddiſh Spike.

14. TRIFOLIUM *montanum anguſtiſſimum ſpicatum. C. B. P.* Narrow-leaved ſpiked Trefoil.

15. TRIFOLIUM *ſtellatum. C. B. P.* Rough ſtarry-headed Trefoil.

16. TRIFOLIUM *lagopoides hirſutum anguſtifolium Hiſpanicum, flore ruberrimo. Mor. Hiſt.* Hairy narrow-leaved Hare's-foot Spaniſh Trefoil, with a very red Flower.

17. TRIFOLIUM *Ægyptiacum, floribus albicantibus, foliis oblongis, vulgo* Berſain. *Jeſſieu.* Egyptian Trefoil, with whitiſh Flowers and oblong Leaves, *commonly called* Berſain.

18. TRIFOLIUM *Creticum bituminoſo ſimile, plane inodorum, flore purpureo. Tourn. Cor.* Trefoil of Candy, reſembling the bituminous one, but without Smell, with a purple Flower.

19. TRIFOLIUM *Creticum elegantiſſimum, magno flore. Tourn. Cor.* The moſt beautiful Trefoil of Candy, with a large Flower.

20. TRIFOLIUM *ampliſſimo folio ſubrotundo villoſo, flore purpuraſcente. Tourn. Cor.* Trefoil with a very large roundiſh hairy Leaf, and a purpliſh Flower.

21. TRIFOLIUM *orientale altiſſimum, caule fiſtuloſo, flore albo. Tourn. Cor.* The talleſt Eaſtern Trefoil, with a hollow Stalk, and a white Flower.

22. TRIFOLIUM *orientale majus villoſiſſimum, floribus flaveſcentibus. Tourn. Cor.* The greater and more hairy Eaſtern Trefoil, with yellowiſh Flowers.

23. TRIFOLIUM *clypeatum argenteum. Alp. Exot.* Silvery Target-ſhap'd Trefoil.

24. TRIFOLIUM *Apulum annuum, calyce veſicario. Hort. Piſſ.* Annual Trefoil of Apulia, with a Bladder Empalement.

The firſt of theſe Plants is greatly cultivated in *England* for feeding of Cattle, and is eſteem'd very profitable, becauſe the great Quantity of Cattle which this Graſs will maintain, does very much inrich all clayey Lands, and prepare them for Corn in two or three Years, which is the Length of Time which this Crop will continue good.

In the Choice of this Seed, that which is of a bright yellowiſh Colour, a little inclining to Brown, ſhould be preferr'd; but that which is Black, ſhould be rejected as good for little.

Ten or twelve Pounds of this Seed will be ſufficient for an Acre of Ground; for if the Plants do not come up pretty thick, it will not be worth ſtanding. The Land in which this Seed is ſown ſhould be well ploughed, and harrowed very fine, otherwiſe the Seeds will be buried too deep, and thereby loſt.

The beſt time to ſow it is about the Beginning of *Auguſt* at which time the *Autumnal* Rains will bring up the Plants in a ſhort time; whereas when the Seeds are ſown in the *Spring*, if it be done very early, they are many times burſt with Wet and Cold; and if it be done late, they are in Danger of miſcarrying from Drought: Whereas in *Autumn*, when the Ground has been warm'd by the *Summer*'s Heat, the Rains then falling do greatly promote the Vegetation of Seeds and Plants.

This Seed ſhould be harrow'd in with Buſhes, for if it be done with a common Harrow, they will be bury'd too deep.

Moſt People have recommended the Sowing of this Seed with ſeveral Sorts of Corn; but if it be ſown at the Seaſon before directed, it will be much better, if ſown alone; for the Corn prevents the Growth of the Plants until it is reaped, and taken off the Ground; ſo that one whole Seaſon is loſt, and many times, if there be a great Crop of Corn upon the Ground, it often ſpoils the *Clover*, ſo that it is hardly worth ſtanding; whereas in the Way before directed, the Plants will have good Root before *Winter*, and in the *Spring* will come on much faſter than that which was ſown the *Spring* before under Corn.

About the Middle of *May* this Graſs will be fit to cut, when there ſhould be great Care taken in making it, for it will require a great deal more Labour and Time to dry than common Graſs, and will ſhrink into leſs Compaſs; but if it be not too rank, it will make extraordinary rich Food for Cattle. The Time for cutting it is when it begins to flower, for if it ſtands much longer, the lower Part of the Stems will begin to dry, whereby it will make a leſs Quantity of Hay, and that not ſo well flavour'd.

Some People cut three Crops in one Year of this Graſs, but the beſt Way is to cut but one in the *Spring*, and feed it the remaining Part of the Year, whereby the Land will be enriched, and the Plants will grow much ſtronger.

One Acre of this Graſs will feed as many Cattle as four or five Acres of common Graſs: But great Care ſhould be taken of the Cattle when they are firſt put into it, leſt it burſt them. To prevent which, ſome turn them in for a few Hours only at firſt, and ſo ſtint them as to Quantity, and this by Degrees, letting them at firſt be only one Hour in the Middle of the Day, when there is no Moiſture upon the Graſs, and ſo every Day ſuffer them to remain a longer time, until they are fully ſeaſon'd to it: But great Care ſhould be had never to turn them into this Food in wet Weather; or if they have been for ſome time accuſtomed to this Food, it will be proper to turn them out at Night in wet Weather; and let them have Hay, which will prevent the ill Conſequences of this Food: But there are ſome who give Straw to their Cattle while they are feeding upon this Graſs, to prevent the ill Effects of it; which muſt not be given them in the Field, becauſe they will not eat it where there is Plenty of better Food. There are others who ſow Rye Graſs amongſt their *Clover*, which they let grow together, in order to prevent the ill Conſequences of the Cattle feeding wholly on *Clover*: But this is not a commendable Way, becauſe the Rye Graſs will greatly injure the *Clover* in its Growth.

Where the Seeds are deſign'd to be ſav'd, the firſt Crop in the *Spring* ſhould be permitted to ſtand until the Seeds are ripe, which may be known by the Stalks and Heads changing to a brown Colour; then it ſhould be cut in a dry time: And when it is well dry'd, it may be hous'd until *Winter*, when the Seeds ſhould be threſh'd out; but if the Seeds are wanted for immediate ſowing, it may be threſh'd out before it be hous'd or ſtack'd, but then it muſt be well dry'd, otherwiſe the Seeds will not quit their Huſks.

It has been a great Complaint amongſt the Farmers, that they could not threſh out theſe Seeds without great Labour and Difficulty, which I take to be chiefly owing to their cutting the *Spring* Crop when it begins to flower, and to leave the ſecond Crop for Seed, which ripens ſo late in *Autumn*, that there is not Heat enough to dry the Huſks ſufficiently, whereby they are tough, and the Seeds render'd difficult to get out, which may be intirely remedied by the leaving of the firſt Crop for Seed, as hath been directed.

When Cattle are fed with this Hay, the beſt Way is to put it in Racks, otherwiſe they will tread a great Quantity of it down with their Feet. This Feed is much better for moſt other Cattle than Milch Cows, ſo that theſe ſhould rarely have any of it, leſt it prove hurtful to them; tho' when it is dry, it is not near ſo injurious to any ſort of Cattle as when green.

The ſecond and third Sorts grow wild in Meadows amongſt the Graſs, where their Roots will abide many Years and are cut with the Graſs, and dry'd for Food: But theſe are rarely cultivated in *England*, becauſe they are Plants of much ſmaller Growth than the *Clover*.

The fourth Sort is an annual or biennial Plant, which periſhes as ſoon as the Seeds are ripe. This grows wild in divers Parts of *England* amongſt Corn, or upon other arable Land, and is ſeldom cultivated unleſs in Botanick Gardens, it being a medicinal Plant.

The fifth and ſixth Sorts do alſo grow wild in *England*, but are often preſerv'd in Botanick Gardens for Variety. The fifth Sort produces Heads very like a Strawberry, from whence it had its Name; and the ſixth Sort has Heads very like Hops, for which Diverſity they are ſometimes cultivated in Gardens, but they are not apply'd to any Uſe.

The ſeventh, eighth, and ninth Sorts are alſo preſerved in Gardens for Variety, where they are planted in Pots, and ſhelter'd in *Winter* amongſt other Exotick Plants; but the ſeventh and eighth Sorts will endure the Cold of our ordinary *Winters* in the open Air, provided they are planted on a dry Soil, and in a warm Situation; but the ninth Sort requires to be ſhelter'd from ſevere Froſt, but ſhould have as much free Air as poſſible in mild Weather.

Theſe Plants may be propagated either from Seeds, or by planting Cuttings of them in the *Spring*, upon a Bed of rich, light Earth, obſerving to water and ſhade them until they have taken Root; after which they muſt be carefully clear'd from Weeds during the *Summer* Seaſon, and in *Auguſt* ſome of the Plants ſhould be taken up and planted in Pots fill'd with light, ſandy Earth, which in *Winter* ſhould be placed under a common Hot-bed Frame, where they may have Air in mild Weather; but in froſty Weather may be ſhelter'd with Glaſſes, &c. If they are propagated from Seeds, theſe ſhould be ſown towards the latter End of *March* upon a Bed of light Earth, and when the Plants are come up, they muſt be carefully clear'd from Weeds, that they may not be over-borne thereby; and when they are about four Inches high, they ſhould be planted either into Pots, or the Borders where they are to remain, becauſe if they are ſuffer'd to grow very rank before they are removed, they do not bear tranſplanting ſo well. Theſe plants are preſeved in Gardens more for the ſake of Variety than any real Beauty, eſpecially the two firſt, which ſmell ſo ſtrong of Bitumen, when bruis'd, as ſcarcely to be borne without Uneaſineſs.

The tenth Sort grows wild in Paſtures in many Parts of *England*, and is cut with the Hay, as is the common Trefoil; from which it differs in having longer and narrower Leaves, and the Flowers being of a deeper red Colour.

The eleventh Sort grows wild in *Italy*, *Spain*, and the South of *France*; from whence the Seeds have been procured by ſome Perſons who are Lovers of Botany, who preſerve this Plant in their Gardens for the ſake of Variety. This is an annual Plant, ſo the Seeds ſhould be ſown in *Autumn*, where the Plants are to remain; and in the *Spring* they muſt be kept clear from Weeds, which is all the Culture they require. In *May* the Plants will flower, and their Seeds will ripen in *July*. The Branches of this Sort trail on the Ground, and the Flowers are produced on Pedicles, from the Diviſions of the ſmall Branches, which are of a bright red Colour, and collected in ſmall globular Heads.

The twelfth Sort is frequently found wild on barren ſandy Lands, in ſeveral Parts of *England*, ſo is not admitted into Gardens, this Sort has been by ſome Perſons propoſed to be cultivated for the Improvement of barren Land; but as it is a very ſmall Plant, and but an Annual, ſo it is not worth the Trial, becauſe the *Noneſuch* will thrive on any Soil where this will grow, and is a much ſtronger Plant; and if the Seeds are permitted to ſcatter in the manner I have directed, will produce a conſtant Supply of young Plants.

The thirteenth Sort grows wild in *Germany*, and ſeveral other Parts of *Europe*, but is not a Native of this Country

This Plant produces very long Spikes of reddiſh Flowers, which make a pretty Appearance, during the Time they continue in Beauty. This Plant is preſerved by the Curious in Botany for the ſake of Variety, but is ſeldom cultivated in other Gardens.

The fourteenth Sort produces very narrow Leaves, and ſlender Spikes of Flowers, which are of a pale red Colour, and being very ſmall, make but an indifferent Appearance. This is not a Native of this Country.

The fifteenth Sort grows wild in the South of *France*, in *Italy* and *Sicily*; from whence the Seeds have been obtained by ſome curious Perſons. This Sort produces ſtarry Heads on the Tops of the Stalks, ſo is preſerved for the ſake of Variety.

The ſixteenth Sort produces very beautiful red Flowers, which make a fine Appearance, ſo may be allowed a Place in ſome barren Part of the Garden, where few better Things will grow; or if the Seeds of this Kind were preſerved in Quantity ſufficient to ſow a ſmall Field in Sight of a Houſe, it would afford a very agreeable Proſpect when in Flower; and the Graſs is as proper Food for Cattle, as the common Trefoil; but this being an annual Plant, is not ſo proper to cultivate in common, becauſe it requires an annual Culture.

The ſeventeenth Sort is cultivated in *Egypt* for feeding of their Cattle, and alſo in ſome other eaſtern Countries. The Seeds of this Sort have been brought into *Europe* by ſome Perſons who were deſirous of having it cultivated here for the ſame Purpoſes; but this being an annual Plant alſo, is not ſo proper as the Clover, for the Reaſons before given; beſides, it being a tall ſlender Plant, is very ſubject to be beaten down by hard Rains, which will greatly damage it.

The nineteenth, twentieth, twenty-ſecond, twenty-third and twenty-fourth Sorts, are all of them annual Plants, which are preſerved in ſome curious Botanic Gardens, for the ſake of Variety; but are not cultivated for Uſe. The Seeds of all theſe annual Trefoils ſhould be ſown in *Autumn*, early enough for the Plants to get Strength before the Froſt comes on; for when the Seeds are ſown in the *Spring*, they frequently fail; and thoſe Plants which ariſe, ſeldom grow to any Magnitude, and rarely perfect their Seeds well. Some of theſe Sorts, which are remarkable for the Colours of their Flowers, are worth propagating in ſmall Patches in Paddocks, where they will afford an agreeable Variety, if they are permitted to flower.

The eighteenth and twenty-firſt Sorts are of longer Continuance than the other Sorts; but theſe are unfit for Fodder, ſo are only preſerved by ſome curious Perſons in their Gardens. Theſe may be propagated by Seeds, in the ſame manner as the other Sorts, and will live abroad in *Winter*, if they are planted in a warm Situation, and on a dry Soil. The ninth Sort may alſo be propagated by Cuttings, which ſhould be planted on a ſhady Border, where, if they are duly watered, they will ſoon take Root; and they may remain in this Border till *Michaelmas*, when they ſhould be planted where they are deſigned to remain.

TRIOSTEOSPERMUM, Doctor *Tinkar*'s Weed, or falſe *Ipecacuana*.

The *Characters* are;

It hath a tubulous Flower conſiſting of one Leaf, divided into five roundiſh Segments, and incloſ'd in a five-leav'd Empalement, having another Cup reſting on the Embryo; which afterward becomes a roundiſh fleſhy Fruit, incloſing three hard Seeds, which are broad at their upper Part, and narrower at Bottom.

We have but one *Species* of this Plant; *viz.*

TRIOSTEOSPERMUM *latiore folio, flore rutilo. Hort. Elth.* Broad-leav'd Trioſteoſpermum, with a reddiſh Flower, commonly called Dr. *Tinkar*'s Weed, or falſe *Ipecacuana*.

This Plant is a Native of *New-England*, *Virginia*, and ſome other Northern Parts of *America*, where it has been frequently uſed as an Emetic, and is commonly called *Ipecacuana*. One of the firſt Perſons who brought it into Uſe, was Dr. *Tinkar*, from whence many of the Inhabitants call it by the Name of *Dr. Tinkar's Weed*. The Leaves of this Plant greatly reſemble thoſe of the true *Ipecacuana*, but the Roots are very different; and by the moſt authentic Account we have of the true Sort, it differs in Flower and Fruit from this Plant.

It grows on low marſhy Grounds, near *Boſton* in *New-England*, very plentifully; where the Roots are taken up every Year, and are continued in Uſe amongſt the Inhabitants of *Boſton*.

This Plant is preſerved in ſeveral curious Gardens in *England*, and is hardy enough to thrive in the open Air: but it ſhould be planted on a moiſt light Soil; for if it is on a dry Ground, there muſt be Care taken to water the Plants conſtantly in dry Weather, otherwiſe they will not thrive. It may be propagated by Seeds, which ſhould be ſown on a Border of light Earth, where the Morning Sun only comes on it; but if theſe Seeds are ſown in the *Spring*, they will remain in the Ground a whole Year, before the Plants will come up: ſo that during this Time the Border muſt be conſtantly kept clear from Weeds; and the following *Spring*, when the Plants appear, they ſhould be duly watered in dry Weather, which will greatly promote the Growth of the Plants. They muſt alſo be conſtantly kept clean from Weeds, which, if permitted to grow amongſt them, will ſoon over-bear the Plants while they are young; and either quite deſtroy the Plants, or ſo much weaken them, that they will not recover it in a long time.

The Plants may remain in this Seed-border, until the *Michaelmas* following, when they ſhould be carefully taken up, and tranſplanted where they are deſigned to remain. Some of them ſhould be planted in Pots, that they may be ſheltered in *Winter*, leſt thoſe which are in the full Ground ſhould be deſtroyed by ſevere Froſt.

This Plant may be alſo propagated by parting of the Roots. The beſt Seaſon for this Work is in the *Spring*, juſt before the Plants begin to ſhoot, which is commonly about the Middle or latter End of *March*; but in doing of this, the Roots muſt not be parted too ſmall, for that will prevent their flowering ſtrong. This Plant uſually grows about two Feet high, and the Flowers come out from the Wings of the Leaves, which being ſmall, make no great Figure in a Garden. However, a few of the Plants may be allow'd a Place in ſome moiſt wilderneſs Quarters, where they are not too much over-ſhaded by Trees; where they will thrive, and add to the Variety.

This Plant perfects its Seeds in this Country every Year; which, if ſown in *Autumn* as ſoon as they are ripe, the Plants will come up the following *Spring*; by which a whole Year is ſaved. Theſe ſeedling Plants will not flower until the third Year; and then they ſeldom grow ſo ſtrong as the older Plants.

TRIPETALOUS FLOWERS, are ſuch as conſiſt of three Leaves, which are call'd *Petals*, to diſtinguiſh them from the Leaves of Plants.

TRIPOLIUM; *vide* Aſter.

TRITICUM; [ſo call'd of *Triturare*, *Lat.* to *threſh*, becauſe the Seeds or Grains are ſeparated from the Ears or Spikes by threſhing.] Wheat.

The *Characters* are;

It hath an apetalous Flower, which is diſpos'd into Spikes; each ſingle Flower conſiſts of many Stamina (or Threads), which are included in a ſquamous Flower-cup, which hath Awns, the Pointal alſo riſes in the Centre, which afterwards becomes an oblong Seed, which is convex on one Side, but hath a Furrow on the other; is farinaceous, and incloſ'd by a Coat which was before the Flower-cup: Theſe are produc'd ſingly, and are collected in a cloſe Spike, being affix'd to an indented Axis.

The *Species* are;

1. TRITICUM *hybernum ariſtis carens. C. B. P.* White or red Wheat without Awns.
2. TRITICUM *ſpica & granis rubentibus. Raii. Syn.* Red Wheat, *in ſome Places call'd* Kentiſh Wheat.
3. TRITICUM *ſpica & granis albis. Raii Syn.* White Wheat.
4. TRITICUM *ariſtis circumvallatum, granis & ſpica rubentibus, glumis lævibus & ſplendentibus. Raii. Syn.* Red-ear'd bearded Wheat.
5. TRITICUM *ſpica villoſa quadrata longiore, ariſtis munitum. Hiſt. Ox.* Cone Wheat.
6. TRITICUM *ariſtatum, ſpica maxima cinericea, glumis hirſutis. Raii Syn.* Grey Wheat, *and in ſome Places*, Duck-bil Wheat, *and* Grey Pollard.
7. TRITICUM *majus, longiore grano, glumis foliaceis incluſo, ſeu Triticum Poloniæ dictum. Hiſt. Ox.* Polonian Wheat.
8. TRITICUM *ſpica multiplici. C. B. P.* Many-ear'd Wheat.
9. TRITICUM *æſtivum. C. B. P.* Summer Wheat.
10. TRITICUM *ſpica hordei Londinenſibus. Raii Syn.* Naked Barley, *vulgo*.
11. TRITICUM *rufum hexaſtychon. C. P. B.* Six-row'd Wheat.

12. **Triticum** *ſemine oblongo. C. B. P.* Long-grain'd Wheat.

13. **Triticum** *ariſtis longioribus, ſpicâ albâ. C. B. P.* White-ear'd Wheat, with long Awns.

The ten firſt Sorts of *Wheat* are cultivated in divers Parts of *England*, but the Manner of ſowing and managing them being ſo well known to moſt Farmers, and being more proper for a Treatiſe of Husbandry than of Gardening, I ſhall omit it in this Place.

The eleventh Sort is not very common in *England* at preſent. This has ſix Rows of Grains to each Ear or Spike; but the Spikes are not ſo long as in ſome of the other Sorts: but it is very much eſteem'd for the Goodneſs of the Grain in *Savoy*, where it is chiefly cultivated.

The twelfth Sort I have obſerved in ſome Parts of *Kent*, where it is by ſome Farmers cultivated. This produces a longer Grain than moſt other Sorts, but is not ſo full; and having more Chaff, is not ſo much eſteem'd as ſome other Sorts.

The thirteenth Sort is frequently cultivated in moſt Parts of *England*, and is eſteemed a very hardy Sort of Corn. The Awns of this Sort are as long as thoſe of *Rie*; ſo that by unskilful Perſons it is frequently taken for it, while it is ſtanding on the Field.

Of all the Sorts of Wheat now cultivated in this Country, the *Cone* Wheat is chiefly preferr'd, as being a larger Ear, and a fuller Grain, than any other Sort. But the Seeds of theſe Corns ſhould be annually changed; for if they are ſown on the ſame Farm, where they are ſaved for ſome Years, they will not ſucceed ſo well as when the Seed is brought from a diſtant Country; nay, it is a much better Method to procure the Seeds from *Sicily*, or ſome other Corn Country, than to ſow *Engliſh* Seeds. The Husbandmen in the *Low Countries* annually procure their Seed Wheat from *Sicily*, or the Iſlands of the *Archipelago*; which they find thrives much better, and produces a finer Grain, and is alſo not ſo liable to Smut, as the Corn of their own ſaving.

TRIUMFETTA.

The *Characters* are;

It hath a Flower conſiſting of ſeveral Petals, which are placed circularly, and expand in form of a Roſe: from whoſe Empalement ariſes the Pointal, which afterward becomes a hard ſpherical burry Fruit, incloſing four angular Seeds.

The *Species* are;

1. **Triumfetta** *fructu echinato racemoſo. Plum. Nov. Gen.* Triumfetta with a burry-branching Fruit.
2. **Triumfetta** *fructu echinato racemoſo, minor. Millar.* Smaller Triumfetta, with a burr-branching Fruit.

The firſt of theſe Plants is very common in the Iſland of *Jamaica*, and ſeveral other Parts of *America*; but the ſecond Sort is more rare, being found in but few Places. The Seeds of this Kind were ſent to *England* by Mr. *Robert Millar*, who diſcovered the Plant on the North Side of the Iſland of *Jamaica*.

Theſe are both very tender Plants, ſo muſt be preſerved in the warmeſt Stoves, otherwiſe they will not live thro' the *Winter* in this Country. They are propagated by Seeds, which muſt be ſown on a Hot-bed early in the *Spring*; and when the Plants are come up, they ſhould be each tranſplanted into a ſeparate Pot filled with light freſh Earth, and then plunged into a moderate Hot-bed of Tanners-bark, and ſhaded from the Sun until they have taken new Root; after which Time they muſt be treated in the ſame manner as hath been directed for other tender exotic Plants. During the *Summer* Seaſon the Plants may remain in this Hot-bed, but in *Autumn* they muſt be removed into the Stove, and plunged into the Bark-bed, obſerving to water them frequently; but in very cold Weather it muſt not be given to them in large Quantities. If the Plants live thro' the *Winter*, they will flower the following *June*, ſo will ripen their Seeds in *September*; but the Plants may be continued two or three Years, provided they are carefully managed.

The Flowers of theſe Plants are ſmall, and of a yellow Colour, ſomewhat like thoſe of *Agrimony*; for which the Plant has been by ſome ranged under the Genus. Theſe Flowers are produced in Branches at the Extremity of the Shoots; but as they are not very beautiful, ſo they are ſeldom preſerved but in ſuch Gardens, where Variety is chiefly intended.

The firſt of theſe Sorts riſes to the Height of ſix or ſeven Feet, and the Stem becomes woody. Toward the Top it divides into ſeveral Branches, each of which produces a Spike or Bunch of Flowers. The Leaves of this Sort are pretty large, and ſhap'd like thoſe of the larger *Malvinda*.

The ſecond Sort ſeldom riſes more than three Feet high, and has ſmaller Leaves than the firſt. The Stem of this Sort is woody, but it doth not branch ſo much as the former, and is in every reſpect a much leſs Plant than that.

TUBEROSE; *vide* Hyacinthus Tuberoſus.

TUBEROUS ROOTS, are ſuch as conſiſt of an uniform fleſhy Subſtance, and are of a roundiſh Figure, as Turnips, *&c.*

TUBULOUS PLANTS, are ſuch whoſe Stems are hollow like a Pipe.

TULIPA, [is a *Turkiſh* Name, ſignifying a *Turkiſh* Cap or Turbant] Tulip.

The *Characters* are;

It hath a Lily Flower, compos'd for the moſt part of ſix Leaves, ſhap'd ſomewhat like a Pitcher; the Pointal, which ariſes in the Middle of the Flower, ſurrounded with Stamina, *afterwards becomes an oblong Fruit, which opens into three Parts, is divided into three Cells, and full of plain Seeds, which reſt upon one another in a double Row. To theſe Marks muſt be added, a coated Root, with Fibres in the lower Part.*

It would be to little Purpoſe to enumerate the ſeveral Varieties of theſe Flowers, which may be ſeen in one good Garden, ſince there is no End of their Numbers; and what ſome People may value at a conſiderable Rate, others reject; and as there are annually a great Quantity of new Flowers obtain'd from Breeders, ſo thoſe which are old, if they have not very good Properties to recommend them, are thrown out and deſpis'd: I ſhall therefore point out the Properties of a good *Tulip*, according to the Characteriſticks of the beſt Floriſts of the preſent Age. 1. It ſhould have a tall, ſtrong Stem. 2. The Flower ſhould conſiſt of ſix Leaves, three within, and three without; the former ought to be larger than the latter. 3. Their Bottom ſhould be proportioned to their Top, and their upper Part ſhould be rounded off, and not terminate in a Point. 4. Theſe Leaves, when opened, ſhould neither turn inward nor bend outward, but rather ſtand erect, and the Flower ſhould be of a middling Size, neither over large nor too ſmall. 5. The Stripes ſhould be ſmall and regular, ariſing quite from the Bottom of the Flower; for if there are any Remains of the former ſelf-colour'd Bottom, the Flower is in Danger of loſing its Stripes again. The Chives ſhould not be yellow, but of a brown Colour. When a Flower has all theſe Properties, it is eſteem'd a good one.

Tulips are generally divided into three Claſſes, according to their Seaſons of Flowering; as, 1. *Præcoces* or early Blowers, *Media's* or Middling Blowers, and *Serotines* or Late Blowers; but there is no Occaſion for making any more Diſtinctions than two, *viz.* Early and Late Blowers.

The Early Blowing *Tulips* are not near ſo fair, nor riſe half ſo high as the Late ones, but are chiefly valued for appearing ſo early in the *Spring*; ſome of which will flower the Beginning of *February*, if planted near a Wall, Pale, Hedge, or other Shelter; and the others do ſucceed them, ſo that they keep flowering until the general Seaſon for theſe Flowers is come, which is towards the End of *April*. As theſe Early Blowing *Tulips* are but few, ſo I ſhall inſert the Names of the principal of them, which are as follow:

1. *Duke Van Toll,* or *Winter Duke.*
2. *General Duke.*
3. *General Brancion.*
4. *Pretty Betty.*
5. *Ducheſs* of *Brancion.*
6. *Lac Verine.*
7. *Violet Ratgans.*
8. *Violet Remow* or *Pourpre Liſſe*
9. *Palto Van Leyden.*
10. *Floriſante.*
11. *Blindenburgh.*
12. *Nonſuch.*
13. *Admiral Crinki.*
14. *General Molſwick.*
15. *Paragan Cleremont.*
16. *Admiral Encuſen.*
17. *Morillion.*
18. *Nobleſt.*
19. *Early Perfect.*
20. *Superintendant.*
21. *Vice-Roy.*
22. *Maria.*
23. *Aurora Van Bart.*
24. *Paragon Grebberi.*
25. *Galatea.*
26. *Marquis.*
27. *Gilden Bloemen.*
28. *Alcetus.*
29. *Jeweel Van Haerlem.*
30. *Jacht Van Delft.*
31. *Goude Son.*
32. *Flamboyant.*
33. *Bruyd Renard.*
34. *Palamedes.*
35. *Apollo.*
36. *Juno.*
37. *Silver-Boot.*
38. *Florida Voorhelm.*
39. *Roy d' Eſpagne.*
40. *Mertopolit.*
41. *Konings-kroon.*

Theſe are the Names which have been impos'd on theſe Flowers by the Floriſts of the ſeveral Countries where they were rais'd, and by which the Roots may be obtained from *Flanders* and *Holland*, where the Floriſts are very exact in keeping up their Liſts of theſe Flowers complete.

The Roots of theſe Early Blowing *Tulips* ſhould be planted the Beginning of *September* in a warm Border, near a Wall, Pale, or Hedge; becauſe if they are put into an open Spot of Ground, their Buds are in Danger of ſuffering by Morning Froſts in the *Spring*. The Soil for theſe ſhould be renewed every Year, where People intend to have them fair. The beſt Soil for this Purpoſe is that which is taken from a light ſandy Paſture, with the Turf rotted amongſt it, and to this ſhould be added a fourth Part of Sea Sand. This Mixture may be laid about ten Inches deep, which will be ſufficient for theſe Roots, which need not be planted more than four or five Inches deep at moſt. The Off-ſets ſhould not be planted amongſt the blowing Roots, but in a Border by themſelves, where they may be planted pretty cloſe together, eſpecially if they are ſmall; but theſe ſhould be taken up when the Leaves decay, and in the ſame manner as the blowing Roots, otherwiſe they would rot, if the Seaſon ſhould prove very wet; for theſe are not ſo hardy as the late Blowers, nor do they increaſe half ſo faſt as thoſe, ſo that a greater Care is required to preſerve the Off-ſets of them.

When theſe *Tulips* come up in the *Spring*, the Earth upon the Surface of the Borders ſhould be gently ſtirr'd and clear'd from Weeds; and as the Buds appear, if the Seaſon ſhould prove very ſevere, it will be of great Service to cover them with Mats; for want of which many times they are blighted, and their Flowers decay before they blow, which is often injurious to their Roots, as is alſo the cropping of the Flowers ſo ſoon as they are blown, becauſe their Roots, which are form'd new every Year, are not at that time arrived to their full Magnitude, and are hereby depriv'd of their proper Nouriſhment.

If when theſe Flowers are blown, the Seaſon ſhould prove very warm, it will be proper to ſhade them with Mats, *&c.* in the Heat of the Day; as alſo if the Nights are froſty, they ſhould be in like manner covered, whereby they may be preſerved a long time in Beauty; but when their Flowers are decayed, and the Seed Veſſels begin to ſwell, they ſhould be broken off juſt at the Top of the Stalks, becauſe if they are permitted to ſeed, it will injure the Roots.

When the Leaves of theſe Flowers are decayed, (which will be before the late Blowers are out of Flower) their Roots ſhould be taken up, and ſpread upon Mats in a ſhady Place to dry; after which they ſhould be clear'd from their Filth, and put up in a dry Place, where the Vermin cannot come to them, until the Seaſon for planting them again, being very careful to preſerve every Sort ſeparate, that you may know how to diſpoſe of them at the time for planting them again; becauſe it is the better Way to plant all the Roots of each Sort together (and not to intermix them, as is commonly practis'd in moſt other Kinds of Flowers;) for as there are few of them which blow at the ſame Time, ſo when the ſeveral Roots of one Sort are ſcattered thro' a whole Border, they make but an indifferent Appearance; whereas when twenty or thirty Roots of the ſame Sorts are placed together, they will all flower at the ſame Time, and afford a more agreeable Proſpect.

There are many curious Perſons, who, in order to preſerve their ſeveral Kinds of *Tulips*, and other bulbous-rooted Flowers ſeparate, have large flat Boxes made, which are divided into ſeveral Parts by ſmall Partitions, each of which is numbered in the ſame Manner as the Diviſions of their Beds; ſo that when a Catalogue of their Roots is made, and the Numbers fixed to each Sort in the Beds, there is nothing more to do when they take up their Roots, but to put every Kind into the Diviſion marked with the ſame Number which was placed to each Sort in the Bed, which ſaves a great deal of Trouble in making freſh Marks every Time the Roots are taken up, and effectually anſwers the Purpoſe of preſerving the Kinds ſeparate.

The ſeveral Sorts of theſe early-blowing *Tulips* do riſe to different Heights in their Stems, ſo that ſcarcely any two of them do flower to an equal Height. The *Duke Van Toll* being one of the firſt that appears in the *Spring*, is generally very ſhort ſtalked, and ſo the other Sorts in Proportion to their Earlineſs, are ſhorter than thoſe which ſucced them; and the late-blowing Kinds are all of them conſiderably longer in their Stems than any of the *Præcoces*, or early Blowers; ſo that when they are confuſedly mixed together, they make a very indifferent Appearance.

The late blowing *Tulips* are ſo numerous, that as I before obſerved, it would be to no Purpoſe to attempt to make a Catalogue of them. Theſe are generally obtained from Breeders, which is a Term applied to all ſuch Flowers as are produced from Seeds, which are of one Self-colour, and have good Bottoms and Chives: Theſe do, in Time, break into various beautiful Stripes, according to the Ground of their former Self-colour: But this muſt be entirely thrown off, otherwiſe they don't eſteem a Flower well broke.

Of theſe Breeders there hath been a great Variety brought into *England* from *Flanders* of late Years, which is the grand Nurſery for moſt Sorts of bulbous-rooted Flowers; but there are ſome curious Perſons who have lately obtained many valuable Breeders from Seed ſown in *England*: And doubtleſs, were we as induſtrious to ſow the Seeds of theſe Flowers, as the People of *France* and *Flanders*, we might in a few Years have as great a Variety as is to be found in any Part of *Europe*: For altho' it is ſix or ſeven Years from the ſowing before the Flowers do blow, yet if after the firſt ſowing there is every Year a freſh Parcel ſown, when the ſeven Years are expired, there will be conſtantly a Succeſſion of Roots to flower every Year, which will reward the Expectation, and keep up the Spirit of Raiſing: But it is the Length of Time at firſt, which deters moſt People from the beginning of this Work.

The Manner of propagating theſe Flowers from Seeds is as follows: 1. You ſhould be careful in the Choice of the Seed, without which there can be little Succeſs expected. The beſt Seed is that which is ſaved from Breeders, which have all the good Properties before-related; for the Seeds of ſtriped Flowers do ſeldom produce any Thing that is valuable.

The beſt Method to obtain good Seeds, is to make choice of a Parcel of ſuch breeding *Tulip* Roots as you would ſave Seeds from, and place them in a ſeparate Bed from the Breeders, in a Part of the Garden where they may be fully expoſed to the Sun, obſerving to plant them at leaſt nine Inches deep; for if they are planted too ſhallow, their Stems are apt to decay before their Seed is perfected.

Theſe Flowers ſhould always be expoſed to the Weather, for if they are ſhaded with Mats, or any other Covering, it will prevent their perfecting the Seed. About the Middle of *July* (a little ſooner or later, as the *Summer* is hotter or colder) the Seeds will be fit to gather, which may be known by the Dryneſs of their Stalks, and the Opening of the Seed-veſſels, at which Time it may be cut off, and preſerved in the Pods until the Seaſon for ſowing it, being careful to put it up in a dry Place, otherwiſe it will be ſubject to mould, which will render it good for little.

Having ſaved a Parcel of good Seed, about the Beginning of *September* is the beſt Seaſon for ſowing it; when there ſhould be provided a Parcel of ſhallow Seed-pans or Boxes, which ſhould have Holes in their Bottoms, to let the Moiſture paſs off: Theſe muſt be filled with freſh, ſandy Earth, laying the Surface very even, upon which the Seeds ſhould be ſown as regularly as poſſible, ſo that they may not lie upon each other; then there ſhould be ſome of the ſame light, ſandy Earth ſifted over them, about half an Inch thick. Theſe Boxes or Pans ſhould be placed where they may have the Morning Sun 'till eleven of the Clock, in which Situation they may remain until *October*; at which Time they ſhould be removed into a more open Situation, where they may enjoy the Benefit of the Sun all the Day, and be ſheltered from the North Winds, where they ſhould remain during the *Winter* Seaſon; but in the *Spring*, when the Plants are up, they ſhould be again removed to their firſt Situation, and if the Seaſon ſhould be dry, they muſt be refreſhed with Water, while the Plants remain green, but as ſoon as their Tops begin to decay, there muſt be no more given them, leſt it rot their tender Bulbs; therefore the Boxes ſhould be placed in a ſhady Situation during the *Summer* Seaſon, but not under the Drip of Trees.

Theſe Plants, at their firſt Appearance, have very narrow graſſy Leaves, very like thoſe of Onions, and do come up with bending Heads, in the ſame Manner as they do, ſo that Perſons who are unacquainted with them, may pull them up inſtead of Graſs, whilſt they are very young, before their Leaves are a little more expanded, which is rarely performed the firſt Year; for they ſeldom appear before the Middle of *March*, and they commonly decay about the latter End of *May* or the Beginning of *June*, according as the Seaſon is hotter or colder.

The Weeds and Moſs ſhould alſo be clear'd off from the Surface of the Earth in the Boxes, and a little freſh Earth ſifted over them ſoon after their Leaves decay, which will be of great Service to the Roots; theſe Boxes ſhould be conſtantly kept clear from Weeds, which if permitted to grow therein, when they are pulled up, their Roots will be apt to draw the Bulbs out of the Ground; at *Michaelmas* they ſhould be freſh earth'd again, and as the *Winter* comes on, ſo they muſt be again removed into the Sun as before, and treated in the ſame Manner, until their Leaves decay in the *Spring*, when their Bulbs ſhould be carefully taken up, and planted in Beds of freſh, ſandy Earth, which ſhould have Tiles laid under them, to prevent the Roots from ſhooting downward, which they often do when there is nothing to ſtop them, and thereby are deſtroyed. The Earth of theſe Beds ſhould be about five Inches thick upon the Tiles, which will be ſufficient for nouriſhing theſe Roots while they are young.

The Diſtance which theſe young Bulbs ſhould be allowed need not be more than two Inches, nor ſhould they be planted above two Inches deep; but toward the End of *October*, it will be proper to cover the Beds over with a little freſh Earth, about an Inch deep, which will preſerve the Roots from the Froſt, and prevent Moſs or Weeds from growing over them. But if the *Winter* ſhould be very ſevere, it will be proper to cover the Beds either with Mats or Peaſe-haulm, to prevent the Froſt from entering the Ground, becauſe theſe Roots are much tenderer while young, than they are after they have acquired Strength.

In the *Spring* the Surface of the Ground ſhould be gently ſtirred, to make it clean, before the Plants come up; and if the *Spring* ſhould prove dry, they muſt be frequently refreſhed with Water, during the Time of their Growth; but this muſt not be given to them in great Quantities, leſt it rot their tender Bulbs; and when the Leaves are decayed, the Weeds ſhould be taken off, and the Beds covered with freſh Earth, which ſhould alſo be repeated again in *Autumn*.

In theſe Beds the Bulbs may remain two Years, during which Time they muſt be conſtantly kept clear from Weeds, and in *Spring* and *Autumn* freſh earth'd, in the Manner already directed; after which the Bulbs muſt be taken up, and planted into freſh Beds, at four Inches aſunder, and as many deep, where they may remain two Years more, during which Time they ſhould have the ſame Culture as before: And after that, the Bulbs being large enough to blow, they ſhould be taken up, and planted in freſh Beds, at the uſual Diſtance, and in the ſame Manner as old Roots; where, when they flower, ſuch of them as are worthy to be preſerved ſhould be marked with Sticks, and at the Seaſon for taking up the Bulbs, they muſt be ſeparated from the others, in order to be planted as Breeders, in different Beds, but you ſhould by no Means throw out the reſt, until they have flowered two or three Years, becauſe it is impoſſible to judge exactly of their Value in leſs Time; for many which at firſt flowering do appear beautiful, will afterwards degenerate ſo as to be of little Value, and others which did not pleaſe at firſt, will many times improve, ſo that they ſhould be preſerved until their Worth can be well judged of.

In this Method many Sorts of new Breeders will be annually raiſed, from which there will always be fine Flowers broken, which being the Produce of a Perſon's own Sowing, will be greatly valued, becauſe they are not in other Hands, which is what enhances the Price of all Flowers; and it has been entirely owing to this Method of raiſing new Flowers that the *Dutch* have been ſo famous; amongſt whom the Paſſion for fine *Tulips* did ſome time ſince reign ſo violently, that many of the Floriſts near *Haerlem*, have often given an hundred Ducats for one ſingle Root; which Extravagance was the Occaſion of an Order being made by the *States*, to limit the utmoſt Price that ſhould be afterward given for any *Tulip* Root, were it ever ſo fine.

Having thus given an Account of the Method of raiſing theſe Flowers from Seeds, I ſhall now proceed to the Management of ſuch Roots which are termed Breeders, ſo as to have ſome of them every Year break out into fine Stripes.

There are ſome who pretend to have Secrets how to make any Sort of Breeders break into Stripes whenever they pleaſe; but this I dare ſay is without Foundation; for from many Experiments which I have made in this Kind, I never could find any Certainty of this Matter: All that can be done by Art, is, to ſhift the Roots every Year into freſh Earth, and a different Situation, by which Method I have had very good Succeſs.

The Earth of theſe Beds ſhould be every Year different; for altho' it is generally agreed, that lean, hungry, freſh Earth doth haſten their breaking, and cauſe their Stripes to be the finer, and more beautiful; yet if they are every Year planted in the ſame Sort of Soil, it will not have ſo much Effect on them, as if they were one Year planted in one Sort of Earth, and the next Year in a very different one, as I have ſeveral times experienced.

The beſt Compoſt for theſe Roots is a third Part of freſh Earth from a good Paſture, which ſhould have the Sward rotted with it; a third Part of Sea Sand, and the other Parts ſifted Lime-rubbiſh; theſe ſhould be all mixed together, ſix or eight Months at leaſt before it is uſed, and ſhould be frequently turned, in order to mix the Parts well together. With this Mixture the Beds ſhould be made about eighteen Inches deep, after the following Manner: After the old Earth is taken from out of the Bed to the Depth intended, then ſome of the freſh Earth ſhould be put in about ten Inches thick, this ſhould be levelled exactly, and then Lines drawn each Way of the Bed, chequerwiſe; at ſix Inches Diſtance, upon the Center of each Croſs, ſhould be placed the *Tulip* Roots in an upright Poſition; and after having finiſhed the Bed in this Manner, the Earth muſt be filled in ſo as to raiſe the Bed eight Inches higher, obſerving in doing this, not to diſplace any of the Roots, and alſo to lay the Top of the Beds a little rounding, to throw off the Water.

There are many Perſons who are ſo careleſs in planting their *Tulip* Roots, as only to dig and level the Beds well, and then with a blunt Dibble to make Holes, into which they put the Roots, and then fill up the Holes with a Rake; but this is by no Means a good Method, for the Dibble in making the Holes, preſſes the Earth cloſely on each Side and at the Bottom, whereby the Moiſture is often detained ſo long about the Roots as to rot them; beſides, the Earth being hard at the Bottom of the Bulbs, they cannot ſo eaſily emit their Fibres, which muſt certainly prejudice the Roots.

Theſe Beds ſhould be ſunk, more or leſs, below the Surface, according to the Moiſture or Dryneſs of the Soil, for the Roots ſhould be ſo elevated as never to have the Water ſtand near them long, which is very apt to rot them. So that where the Soil is very wet, it will be proper to lay ſome Lime-rubbiſh under the Earth, in order to drain off the Wet, and the Beds ſhould be entirely raiſed above the Level of the Ground; but to prevent their falling down into the Walks, after Froſt or hard Rains, it will be proper to raiſe the Paths between them, either with Sea-coal Aſhes or Rubbiſh, eight or ten Inches, which will ſupport the Earth of the Beds, and theſe Paths may ſlope at each End from the Middle, which will cauſe the Water to run off as it falls. But where the Soil is dry, the Beds may be ſunk a Foot or fourteen Inches below the Surface; for in ſuch Places the Beds need not be more than four or ſix Inches above the Surface, which will be Allowance enough for their Settling.

During the *Winter* Seaſon there will be no farther Care required, the Roots being planted thus deep will be in no Danger of ſuffering by Froſt; but in the *Spring*, when their Leaves begin to appear above Ground, the Earth upon the Surface of the Beds ſhould be ſtirred, to clear it from Weeds, Moſs, *&c.* and when the Flower-buds begin to come up, they ſhould be guarded from Froſt, otherwiſe they are very ſubject to blight and decay ſoon after they appear; but they need only be covered in ſuch Nights when there is a Proſpect of Froſt, for at all other Times they ſhould have as much open Air as poſſible, without which they will draw up weak, and produce very ſmall Flowers.

When theſe Breeders are in flower, you ſhould carefully examine them, to ſee if any of them have broken into beautiful Stripes, which if you obſerve, there ſhould be a Stick put into the Ground, by every ſuch Root, to mark them, that they may be ſeparated from the Breeders, to plant amongſt the ſtriped Flowers the following Year; but you ſhould carefully obſerve whether they have thrown off their former Colour entirely, as alſo when they decay, to ſee if they continue beautiful to the laſt, and not appear ſmeared over with the original Colour; in both which Caſes they are very ſubject to go back to their old Colour the next Year; but if their Stripes are diſtinct and clear to the Bottom, and continue ſo to the laſt, (which is what the Floriſts call dying well) there is no great Danger of their returning back again, as hath been by ſome confidently reported; for if one of theſe Flowers is quite broken (as it is termed) it will never loſe its Stripes, though ſometimes they will blow much fairer than at others, and the Off-ſets will often be more beautiful than the old Roots.

This Alteration in the Colour of theſe Flowers may be ſeen long before they are blown, for all the green Leaves of the Plant will appear of a fainter Colour, and ſeem to be ſtriped with white, or of a browniſh Colour, which is a plain Proof that the Juices of the whole Plant are altered, or at leaſt the Veſſels through which the Juice is ſtrained, ſo that hereby Particles of a different Figure are capable of paſſing through them, which, when entered into the Petals of the Flower, do reflect the Rays of Light in a different Manner, which occaſions the Variety we ſee in the Colours of Flowers (but this is more fully explained in the Article of *Vegetation*,

tion, which ſee). This breaking of the Colours in Flowers proceeds from Weakneſs, or at leaſt is the Cauſe of Weakneſs in Plants; for it is obſervable, that after *Tulips* are broken into fine Stripes, they never grow ſo tall as before, nor are the Stems, Leaves or Flowers ſo large; and it is the ſame in all other variegated Plants and Flowers whatever, which are alſo much tenderer than they were before they were ſtriped; ſo that many Sorts of exotick Plants, which by Accident become variegated in their Leaves, are often rendered ſo tender as not to be preſerved without great Care, tho' indeed the Striping of *Tulips* doth never occaſion ſo great Weakneſs in them; the greateſt Effect it hath on them, is in leſſening their Growth, cauſing ſome (which while they continued in their original plain Colours, did riſe near three Feet in Height) to advance little more than two Feet, after their Colours were altered; and the more beautifully their Stripes do appear, the ſhorter will be their Stems, and the weaker their Flowers.

There is nothing more to be obſerved in the Culture of ſtriped Flowers, than what has been directed for Breeders, excepting that theſe ſhould be arched over with tall Hoops and Rails, that they may be ſhaded from the Sun in the Day-time, and protected from ſtrong Winds, hard Rains, and froſty Mornings, otherwiſe the Flowers will continue but a ſhort Time in Beauty; but where theſe Inſtructions are duly followed, they may be preſerved in Flower a full Month, which is as long as moſt other Flowers do continue.

There are ſome Perſons who are ſo extremely fond of theſe Flowers, as to have large Frames of Iron-work to cover their Beds of *Tulips*, in ſuch a Manner, that they may walk between two Beds under the Frames, over which are ſpread Tarpawlins, ſo as to keep off Sun, Rain, and Froſt; whereby they can view the Flowers without being at the Trouble of taking off or turning up the Tarpawlin, or being incommoded by the Sun or Rain, which cannot be avoided where the Covering is low: Beſides, by thus raiſing the Covers, the Flowers have a greater Share of Air, ſo that they are not drawn ſo weak as they are when the Covering is low and cloſe to them; but theſe Frames being expenſive, can only be purchaſed by Perſons of Fortune; however, there may be Frames of Wood contriv'd for a ſmall Expence, which being arched over with Hoops, may anſwer the Purpoſe as well as the Iron Frames, tho' they are not ſo ſightly or laſting.

But after their Flowers are faded, their Heads ſhould be broken off, to prevent their ſeeding; for if this is not obſerved, they will not flower near ſo well the following Year, and this will cauſe their Stems to decay ſooner than otherwiſe they would do, ſo that their Roots may be taken up early in *June*; for they ſhould not remain in the Ground long after their Leaves are decayed. In taking theſe Roots out of the Ground, you muſt be very careful not to bruiſe or cut them, which will endanger their rotting; and, if poſſible, it ſhould be done a Day or two after Rain. Theſe Roots muſt be cleared from their old Covers, and all Sorts of Filth, and ſpread upon Mats in a ſhady Place to dry, after which they ſhould be put up in a dry Place, where Vermin cannot get to them, obſerving to keep every Sort ſeparated, but they ſhould not be kept too cloſe from the Air, nor ſuffered to lie in Heaps together, leſt they ſhould grow mouldy, after which they commonly rot when they are planted again.

The Off-ſets of theſe Roots, which are not large enough to produce Flowers the ſucceeding Year, ſhould be alſo put by themſelves, keeping each Sort diſtinct; theſe ſhould be planted about a Month earlier in *Autumn* than the blowing Roots, in particular Beds in the Flower-nurſery, where they may not be expoſed to publick View: But the Earth of the Beds ſhould be prepared for them in the ſame Manner as for larger Roots, tho' theſe muſt not be planted above five Inches deep, and may be placed much nearer together than thoſe which are to flower, and in one Year moſt of them will become ſtrong enough to flower. when they may be removed into the Flower-garden, and placed in the Beds amongſt thoſe of the ſame Kinds.

TULIPIFERA, of *Tulipa*, a *Tulip*, and *fero*, Lat. to *bear*.] The Tulip-tree.

The *Characters* are;

The Flower conſiſts of ſeveral Leaves, which expand in ſuch a Manner, as (by ſome thought) to reſemble a Tulip; the Pointal riſes in the Center of the Flower, ſurrounded by a great Number of Chives, and afterwards becomes a ſquamous Fruit, or Cone growing erect. To theſe Marks may be added, the Leaves, for the moſt part, being angular, the upper Part is hollowed, as if cut off with Sciſſars, terminating in two Points.

The *Species* are;

1. Tulipifera *arbor Virginiana. H. L.* The Virginian Tulip-tree.

2. Tulipifera *Virginiana, laurinis foliis, averſa parte rore cæruleo tinctis Conibaccifera. Pluk. Phyt.* The Laurel-leav'd Tulip-tree, *vulgo.*

The firſt Sort is very common in *America*, where it grows to a great Magnitude, but in *England* there are at preſent but very few of them which have arrived to any conſiderable Stature. This Sort was formerly kept in Pots and Tubs, and houſed in *Winter* with great Care, in which Management the Plants made but poor Progreſs, nor would ever have produced Flowers. But about fifty Years ago there was one of theſe Trees planted out in a Wilderneſs in the Gardens of the Right Honourable the Earl of *Peterborough* at *Parſons-green* near *Fulham*, which ſoon convinced the Curious of their Miſtake in the Culture of this Tree, by the great Progreſs it made, and in a few Years after it produced Flowers. This Tree is yet ſtanding, and annually produces a great Quantity of Flowers, though ſome of the Branches begin to decay, which perhaps may have been occaſioned by its being too cloſely ſurrounded with other Trees, whoſe Roots are ſo much entangled with thoſe of this Tree, that they draw the Nouriſhment of the Ground from it. In ſome Years this Tree produces Cones, but they have not been ever perfected ſo as to contain good Seeds.

There are ſome other Trees of this Kind which have produced Flowers ſeveral Years, though I believe none of them are very large; the biggeſt I have ſeen (excepting that at *Parſons-green*) is not more than twentyfive Feet high; whereas my Lord *Peterborough's* is upwards of fifty Feet high, and is proportionably large in the Trunk; but this has a naked Body near forty Feet high, all the Branches growing near the Top of the Tree, which might be occaſioned by being ſo cloſely ſurrounded with other Trees; for I have obſerved, wherever they have a more open Situation, they are ſubject to extend their Branches, and do not aſpire upwards very much, though they generally have one upright Shoot in the Middle, much after the Manner of the Plane Tree, whoſe Manner of Growth is very like that of this Tree.

The Flowers which theſe Trees produce, are by no means like thoſe of the Tulip, though many Perſons have been ſo incurious as to imagine them ſo, eſpecially the Inhabitants of *America*, who firſt gave the Name of *Tulip-tree* unto this Plant, by which Name it has been ſince called by the Inhabitants of *Europe*, who received it from them with the Plants many Years ſince; but I have not heard that any of theſe Trees have flowered in any Part of *Europe*, except in *England*.

Mr. *Cateſby*, in his *Natural Hiſtory of Carolina*, &c. ſays, There are ſome of theſe Trees in *America*, which are thirty Feet in Circumference, that the Boughs are very unequal and irregular, making ſeveral Bends or Elbows, which makes the Tree diſtinguiſhable at a great Diſtance, even when they have no Leaves upon them. They are found in moſt Parts of the Northern Continent of *America*, from the Cape of *Florida* to *New-England*, where the Timber is of great Uſe.

This Tree may be propagated from Seeds, which are often brought from *America* in the Cones; theſe ſhould be taken out in the *Spring*, and ſown in Pots or Boxes filled with light, freſh Earth, and placed upon a moderate Hot-bed, which ſhould be covered only with Mats, and not have Glaſſes over them, becauſe the Glaſſes will cauſe the Earth to dry too faſt, and thereby ſpoil the Seeds.

Theſe Pots ſhould be frequently refreſh'd with Water, and when the Plants are come up, they ſhould be plac'd in a ſhady Situation during the *Summer* Seaſon, but in *Winter* they muſt be put into a Frame, where they may enjoy the open Air in mild Weather, but muſt be ſhelter'd from Froſt.

In the following *Spring* the Plants ſhould be taken up, and each planted in a ſeparate ſmall Pot, fill'd with light, freſh Earth, and if theſe Pots are plung'd into a moderate Hot-bed, under Mats, it will promote their Rooting; in *Summer* theſe Plants muſt be remov'd into the Shade, and in *Winter* into a Frame as before: After this manner they may be treated three or four Years, until they have acquired Strength, when they may be turn'd out of the Pots in the *Spring*, and planted where they are to remain, which ſhould always be near the Shelter of other Trees, where they will grow much better than in an open Situation, provided they are not too much crowded or over-hung by large Trees.

There are ſome People who propagate this Tree by Layers, but they are commonly two or three Years before they take Root, and theſe do ſeldom make ſo ſtrait Trees as thoſe rais'd from Seeds, though indeed they will produce Flowers ſooner, as is always the Caſe with ſtunted Plants.

This Tree ſhould be planted on a light loamy Soil, not too dry, on which it will thrive much better than upon a ſtrong Clay, or a dry gravelly Ground; for in *America* they are chiefly found on a moiſt deep Soil, where they will grow to a prodigious Size. Though it will not be proper to plant theſe Trees in a Soil which is too moiſt in *England*, becauſe it might endanger the rotting of the Fibres of the Roots, by the Moiſture continuing too long about them, eſpecially if the Bottom be a Clay or a ſtrong Loam, which will detain the Wet.

The *Laurel-leav'd Tulip-Tree* is at preſent very rare in *England*, tho' formerly there were ſeveral of theſe Trees in the Gardens of the Biſhop of *London* at *Fulham*, and thoſe of the Dutcheſs of *Beaufort* at *Chelſea*; but theſe have been ſince loſt, ſo that there are very few of them to be ſeen in the *Engliſh* Gardens. The largeſt Tree of this Kind, which I know at preſent, is in the Gardens of Mr. *Peter Collinſon* at *Peckham*, which has produced a great Number of Flowers the three Years paſt. This Sort is propagated by Layers, for the Seeds do never come up if ſown in *England*; the Layers ſhould remain undiſturb'd two Years, by which Time they will take Root, and may then be taken off in the *Spring*, and planted in Pots fill'd with freſh light Earth, and plac'd upon a moderate Hot-bed, to promote their taking Root; after which they ſhould ſtand in a ſhady Situation during the Heat of *Summer*, but in *Winter* they ſhould be ſhelter'd from the Froſt, eſpecially while young, though when they have acquired Strength, they may be planted out in a warm Situation, where they may be ſhelter'd by other Trees, in which Places, with a little Care, they will endure the Cold of our *Winters* very well, and in a few Years will produce Flowers.

Though I have inſerted this Tree under this Title (which is the Name by which it was firſt brought into *England*,) yet it does not ſtrictly belong to this Place, there being a *Genus* under which this Plant ſhould be ranged, which was eſtabliſh'd by *Pere Plumier*, by the Name of *Magnolia*, in Honour to the learned Botaniſt *Peter Magnol*, Profeſſor of Phyſick and Botany in the Univerſity of *Montpelier*. This Plant is curiouſly figured in the third Part of Mr. *Catesby*'s *Natural Hiſtory of Carolina*, by the Name of *Magnolia lauri folio ſubtus albicante*; he deſcribes it to be a ſmall Tree, ſeldom growing more than ſixteen Feet high, that the Wood is white and ſpongy, cover'd over with a white Bark; the Leaves are in Shape like thoſe of the common *Bay*, of a pale green Colour, and white on their Backſides. In *May* they begin to produce their Flowers, which are white, and very fragrant; theſe are continued the moſt part of *Summer*, during which Time the Woods are perfum'd with their Odour. When the Petals of theſe Flowers are decay'd, the Pointal becomes a conical Fruit, about the Size of a large Walnut, thick ſet with Knobs or Riſings, from each of which, when the Fruit is ripe, are diſcharged flat Seeds, of the Bigneſs of *French Beans*, having a Kernel within a thin Shell, cover'd with a red Skin. Theſe red Seeds, when diſcharged from their Cells, fall not to the Ground, but are ſupported by ſmall white Threads, of about two Inches in length, which makes a very beautiful Appearance. The Fruit is at firſt green; when ripe, red; and when declining, turns brown: The Tree grows naturally in moiſt Places, and often in ſhallow Water; and, what is very extraordinary, they being removed on high, dry Ground, become more regular and handſome, and are more prolifick of Flowers and Fruit. They uſually loſe their Leaves in *Winter*, unleſs it be moderate. It is call'd by ſome *The Sweet Bay*.

There is alſo another Species of this Tree, which hath been lately brought into *England*, which is called by *Pere Plumier*, *Magnolia ampliſſimo flore albo, fructu cæruleo*. This is eſteem'd one of the moſt beautiful Trees in *America*, where they uſually grow in moiſt ſwampy Woods, and do often riſe to the Height of ſixty Feet, or more; the Leaves are much larger than thoſe of our common *Laurel*, and are of a light-green Colour; the Flowers, I am told, are very large, of a whitiſh Colour, and very fragrant. The Fruit is ſhap'd like that of the former Sort, but is much larger, and does emit the Seeds in like manner; ſo that it is in Beauty from *May* to *November*, and the Leaves always remaining green, do afford an elegant Proſpect in *Winter*. They are of quick Growth, and generally riſe with ſtrait Stems, which is a great Addition to their Beauty; and ſince they are hardy enough to endure the Cold of our Climate in the open Ground, I doubt not but in a few Years we ſhall have the Pleaſure of ſeeing its beautiful Flowers, there being ſeveral Trees planted in the Gardens of ſome curious Perſons near *London*, where they have borne the Cold of ſeveral *Winters* without Shelter, and do make conſiderable Progreſs every Year.

This Tree is quick of Growth; for his Excellency the late Colonel *Johnſon*, who was Governor of *South Carolina*, told me, he had taken many ſmall Plants out of the Woods, and planted them near his Habitation, which Trees in three or four Years were grown near twenty Feet high; and ſince thoſe which have been planted in the open Air, in ſeveral curious Gardens near *London*, have made ſo great Progreſs, it is to be hop'd, that this Tree will become more frequent in *England*: For theſe beautiful Trees, which retain their Verdure throughout the Year, will be very ornamental in Wilderneſs Quarters, where being intermix'd with other Trees of the ſame Growth, they will add to the Variety; and when they do come to Maturity, ſo as to produce Flowers and Fruit in this Country, there are not any of the flowering Trees yet known, that will afford a greater Pleaſure than theſe; which ſhould excite a Curioſity in ſuch People who have Opportunities of procuring ſome of theſe Plants from *Carolina*, to bring over as many as they can, ſince the greater Variety of Places they are planted in, the more Chances there are of their ſucceeding; and when the Nature of the Plants are better known in *England*, they may be propagated in greater Plenty than at preſent.

This Tree muſt alſo be obtained in Plants from Abroad, and increas'd by Layers as the former, for the Seeds have not ſucceeded in any Part of *Europe*, where they have yet been ſown; and in the Woods of *America*, where they naturally grow, it is very difficult to find young Plants, the Cattle being ſo fond of 'em, that they generally eat off their Tops ſoon after they appear above-ground; but in little Iſlands, which are ſurrounded by Rivulets, ſo that the Cattle can't eaſily get in, there are great Numbers of theſe Plants; therefore whoever would procure a Quantity of them, muſt always have Recourſe to ſuch Places as are unfrequented by Cattle.

TURKS CAP; *vide* Lilium flore reflexo.

TURKEY WHEAT; *vide* Mays.

TURNERA.

The *Characters* are;

It hath a funnel-ſhaped Flower, conſiſting of five Leaves, which are faſtened to the Calyx, which is monopetalous, and divided into five Parts at the Top: under the Flower-cup there are two Leaves, which join at the Bottom, and ſurround the Cup: from the Center of the Flower-cup ariſes the Pointal, which is divided into three Parts to the Bottom, and ſurrounded by five Stamina. This Pointal afterward becomes an almoſt ſpherical Fruit, which is divided into three Parts, and filled with roundiſh Seeds, which are faſtened to the Placenta by ſlender Threads.

The *Species* are;

1. TURNERA *fruteſcens ulmifolia. Plum. Nov. Gen.* 15. Shrubby Turnera, with an Elm-leaf.
2. TURNERA *fruteſcens, folio longiore & mucronato.* Shrubby Turnera, with a longer pointed Leaf.

Theſe Plants are both of them Natives of the warm Parts of *America*. The firſt *Species* was found by Father *Plumier* in *Martinico*, who gave it the Name of *Turnera*, from Dr. *Turner*, a famous *Engliſh* Phyſician, who lived in Queen *Elizabeth*'s Reign, and wrote a Herbal, in which he has chiefly figured and deſcribed the uſeful Plants.

The other *Species* was diſcovered by Sir *Hans Sloane*, Baronet, who has figured it in his *Natural Hiſtory of* Jamaica, under the following Name; *Ciſtus urticæ folio, flore luteo, vaſculis trigonis*. But both theſe Sorts were obſerved by my late Friend Dr. *William Houſtoun*, in ſeveral Parts of *America*. Theſe grow to the Height of five or ſix Feet, and may be trained into regular Shrubs: they both produce yellow Flowers, which come out at the Foot-ſtalks of the Leaves, and are continued for at leaſt nine Months, which renders them worthy of a Place in the Stove.

The

They may eaſily be propagated, by ſowing their Seeds on a Hot-bed early in the *Spring*; and when the Plants are come up two Inches high, they muſt be tranſplanted into ſmall Pots, and plunged into a Hot-bed of Tanners-bark, obſerving to water and ſhade them until they have taken Root; after which Time they muſt be treated as hath been directed for the *Guava's*; to which the Reader is deſired to turn, to avoid Repetition. The Seeds of theſe Plants will often fall into the Pots which are placed near them in the Stove; which will grow, and ſoon furniſh Plants enough, after a Perſon is once poſſeſſed of them. Theſe Plants are too tender to live in the open Air in *England*; ſo they muſt be placed in the Bark-bed in the Stove; where, during the *Winter* Seaſon, they muſt be kept warm, and frequently watered; but in the *Summer* Seaſon they muſt have a great Share of Air, otherwiſe they will draw up tender, and not produce many Flowers.

When the Plants are grown pretty large, they may be treated more hardily, by placing them in the dry Stove; where, if they are kept in a moderate Degree of Heat, they will thrive and flower very well. Thoſe who would ſave the Seeds of theſe Plants, muſt watch them carefully, becauſe, when they are ripe, they ſoon ſcatter, if they are not gathered.

TURNIP; *vide* Rapa.

TURNSOLE; *vide* Heliotropium.

TURRITIS: Tower-Muſtard.

The *Characters* are;

The Flower conſiſts of four Leaves, which expand in Form of a Croſs, out of whoſe Empalement riſes the Pointal, which afterwards becomes a long ſmooth Pod, which grows for the moſt part upright, and opens into two Parts, in each of which are contain'd many ſmooth Seeds.

The *Species* are;

1. TURRITIS *vulgatior. J. B.* Common Tower-Muſtard.
2. TURRITIS *foliis inferioribus cichoraceis, cæteris perfoliata. Tourn.* Tower-Muſtard, with its under Leaves like thoſe of Cichory, and the upper Leaves like Thorough-wax.
3. TURRITIS *muralis minor. Pet. H. B.* Wall-Creſs, or Tower-Muſtard with Daiſie Leaves.
4. TURRITIS *leucoii folio. Tourn.* Tower-Muſtard with a Stock-gilliflower Leaf.

There are ſeveral other Species of this Plant, which are preſerv'd in curious Botanick Gardens for the ſake of Variety, but as they have little Beauty or Uſefulneſs, ſo they are ſeldom cultivated in other Gardens. The three firſt Sorts do grow wild upon Walls and Buildings in divers Parts of *England*, but the fourth Sort has not been diſcover'd to grow in this Country, except in Gardens.

They may be all cultivated by ſowing their Seeds upon a Bed of light dry Earth in the *Spring*, and when the Plants are come up, they ſhould be tranſplanted where they are to remain for good, obſerving to water 'em until they have taken Root, after which they will require no farther Care, but to clear 'em from Weeds, and the ſecond Year they will produce Seeds, after which the Plants never do continue.

TUSSILAGO: Coltsfoot.

The *Characters* are;

It hath a radiated Flower, whoſe Diſk conſiſts of many Florets, but the Crown is compos'd of many half Florets; the Embryo's are included in a multifid Flower-cup; which are afterwards turn'd to downy Seeds, fix'd in a Bed. To which Notes may be added, The Flowers appearing before the Leaves, in Spring.

The *Species* are;

1. TUSSILAGO *vulgaris. C. B. P.* Common Coltsfoot.
2. TUSSILAGO *Alpina rotundifolia glabra. C. B. P.* Round-leav'd ſmooth Coltsfoot of the Alps.

The firſt of theſe Sorts is very common in watery Places in almoſt every Part of *England*, and is rarely kept in Gardens; for the Roots do creep under-ground, and increaſe ſo faſt, that in a ſhort Time they will ſpread over a large Spot of Ground.

The ſecond Sort grows wild upon the *Alps*, from whence it has been tranſplanted into ſome curious Botanick Gardens for the ſake of Variety; the Flowers of this are purple, and thoſe of the common Sort are yellow.

V A

VACCARIA; *vide* Lychnis.

VACCINIA; *vide* Vitis Idea.

VALERIANA, [ſo called of *valere*, Lat. to *avail*, becauſe of its great Virtues: or of *Valerius*, who firſt made uſe of this Plant in Phyſick. It is the true *Phu* of *Dioſcorides*, or of the Antients; in *Greek* φῦ, of φύω, to *be born*, or *Phu*, of *Phy*, a *Pontic* Word; which laſt denotes the penetrating Odour of this Root.] Valerian.

The *Characters* are;

The Leaves grow by Pairs, oppoſite upon the Stalks; the Flower conſiſts of one Leaf, is tubuloſe, and divided into five Segments at the Top: Theſe Flowers are, for the moſt part, collected into a ſort of Umbel upon the Top of the Stalks, and are ſucceeded by oblong flat Seeds, which are winged with a ſoft Down.

The *Species* are;

1. VALERIANA *hortenſis, Phu cluſatri folio Dioſcoridis. C. B. P.* Great Garden Valerian, *or* Phu.
2. VALERIANA *ſylveſtris magna aquatica. J. B.* Great wild Water Valerian.
3. VALERIANA *major ſylveſtris montana. C. B. P.* Great wild Mountain Valerian.
4. VALERIANA *paluſtris minor. C. B. P.* Small Marſh Valerian.
5. VALERIANA *rubra. C. B. P.* Red Garden Valerian.
6. VALERIANA *rubra anguſtifolia. C. B. P.* Narrow-leav'd red Garden Valerian.
7. VALERIANA *marina latifolia major alba. Mor. Umb.* Great broad-leav'd white Sea Valerian.
8. VALERIANA *Alpina, foliis integris, radice repente, inodora. Raii Hiſt.* Alpine Valerian, with undivided Leaves, and a creeping Root, without Smell.
9. VALERIANA *Alpina prima. C. B. P.* The firſt Alpine Valerian, of *Caſpar Bauhin*.
10. VALERIANA *Alpina altera. C. B. P.* Another Alpine Valerian of *Caſpar Bauhin*.
11. VALERIANA *Alpina, ſcrophulariæ folio. C. B. P.* Alpine Valerian, with a Fig-wort Leaf.
12. VALERIANA *montana, ſubrotundo folio. C. B. P.* Mountain Valerian, with a roundiſh Leaf.
13. VALERIANA *Alpina, nardo Celticæ ſimilis. C. B. P* Alpine Valerian, reſembling the Celtic Spikenard.
14. VALERIANA *Cretica, filipendulæ radice. Inſt. R. H.* Candy Valerian, with a Drop-wort Root.
15. VALERIANA *Celtica. Inſt. R. H.* Celtic Valerian, *or* Spikenard.
16. VALERIANA *marina anguſtifolia, ſive minor alba. Mor. Hiſt.* Narrow-leav'd or ſmaller White Sea Valerian.
17. VALERIANA *Alpina minor. C. B. P.* Smaller Alpine Valerian.
18. VALERIANA *tuberoſa Imperati. Tourn. Cor.* Tuberoſe-rooted Valerian of Imperatus.
19. VALERIANA *orientalis anguſtifolia, floribus & radice Valerianæ hortenſis. Tourn. Cor.* Narrow-leav'd Eaſtern Valerian, with the Flowers and Root of the Garden Valerian.
20. VALERIANA *orientalis, alliariæ folio, flore albo. Tourn. Cor.* Eaſtern Valerian, with a Sauce-alone Leaf, and a white Flower.
21. VALERIANA *orientalis, ſiſymbrii Matthioli folio. Tourn. Cor.* Eaſtern Valerian, with a Water-creſs Leaf.
22. VALERIANA *orientalis minima, flore leucophæo. Tourn. Cor.* The leaſt Eaſtern Valerian, with a whitiſh Flower.
23. VALERIANA *maxima Pyrenaica, cacaliæ folio. D. Fagon. Inſt. R. H.* The greateſt Pyrenean Valerian, with a ſtrange Coltsfoot Leaf.
24. VALERIANA *foliis calcitrapæ. C. B. P.* Valerian with Leaves like thoſe of the Star-thiſtle.
25. VALERIANA *Luſitanica annua latifolia laciniata. Inſt. R. H.* Broad jagged-leav'd annual Valerian of Portugal.

26. VALERIANA *humilis Americana, folio rotundo ſubtus argenteo. Plum.* Dwarf American Valerian, with a round Leaf white underneath.

The firſt of theſe Sorts is propagated in *England* for medicinal Uſe, and is called in the Shops by the Name of *Phu*, to diſtinguiſh it from the *Mountain Valerian*, which is preferred to all the other Sorts, by the modern Phyſicians, tho' the Roots of this firſt are ſtill continued in ſome of the capital Medicines.

This Plant is propagated by parting of its Roots, either in *Spring* or *Autumn*, which ſhould be planted in Beds of freſh, dry Earth, about eight or ten Inches aſunder, (for they commonly ſpread and multiply very faſt); if the Seaſon be dry you muſt water the Plants until they have taken Root; after which they will require no farther Care, but to keep them clean from Weeds, and in *Autumn*, when their Leaves are decayed, the Roots ſhould be taken up and dried for Uſe.

The ſecond Sort is very common in moiſt Places, and by the Sides of Rivers and Ditches in moſt Parts of *England*, but is rarely cultivated in Gardens. The Roots of this Kind, being ſo common near *London*, are generally ſold in the Markets inſtead of the third Sort, which is what ſhould always be uſed, as being by far the ſtrongeſt and moſt valuable.

The third Sort is generally found upon dry chalky Soils, in ſhady Places, in divers Parts of *England*, the Roots of which are much preferable to thoſe of the ſame Kind which are cultivated in Gardens; as are all the Sorts of aromatick Plants, when gathered from their native Places of Growth.

This Plant may be propagated by parting the Roots either in *Spring* or *Autumn*, as was directed for the firſt Sort; but you ſhould always obſerve to plant them upon a dry, freſh, undunged Soil, in which, though the Roots will not make near ſo great Progreſs as in a rich, moiſt Soil, yet they will be much preferable to them for Uſe. Theſe Roots ſhould alſo be taken up, when the Leaves decay, in *Autumn*, and preſerved dry until uſed.

The fourth Sort is very common in moiſt Soils, in divers Parts of *England*, but is ſeldom propagated in Gardens. This is placed among the officinal Simples, in the *College Diſpenſatory*, though it is rarely uſed in Medicine. It may be propagated in a moiſt Soil, by parting the Roots as the former.

The fifth, ſixth and ſeventh Sorts are propagated in Gardens for the Beauty of their Flowers, but they are only proper for large Gardens, being very apt to grow too large for ſmall Places. Theſe may be propagated by parting their Roots, in the Manner before directed, or from Seeds, which ſhould be ſown in *Autumn*, ſoon after they are ripe, upon a Bed of light, freſh Earth; and in the *Spring*, when the Plants come up, they ſhould either be tranſplanted into Nurſery-beds, or the Borders where they are to remain for good.

Some of theſe Plants will flower the firſt Seaſon, but the ſecond Year they will all flower very ſtrong. They commonly grow above three Feet high, and when the Roots are ſtrong, they will continue flowering moſt Part of the *Summer*, which renders them worthy of a Place in large Borders, and alſo in Avenues and other abject Parts of the Garden, they being very hardy, and will grow in almoſt any Soil or Situation; but their Roots will abide longeſt in a dry barren Soil; for in rich, moiſt Places they ſeldom continue more than two Years.

The Seeds of theſe Kinds will often get into the Joints of old Walls, where they will grow and abide many Years, without any Care or Culture, and produce Flowers moſt Part of the *Summer*; and in ſuch a Situation they will endure all Weathers, without the leaſt Injury. Theſe Plants are never uſed in Medicine.

The eighth, ninth, tenth, eleventh, thirteenth and ſeventeenth Sorts grow on the *Alps*, from whence they have been procured by ſome curious Botaniſts, and are preſerved in their Gardens for Variety. Theſe are abiding Plants, which may be propagated by parting of their Roots. The beſt Time to tranſplant theſe Plants, and part their Roots, is ſoon after *Michaelmas*, when their Leaves decay, that they may have good rooting in the Ground before the dry Weather comes on in the *Spring*; otherwiſe they will not flower ſtrong the following *Summer*. All theſe Sorts ſhould be planted on a ſtrong, loamy Soil, and in a ſhady Situation; where they will thrive much better than on a light Earth, and in an open Situation, in which they will not live unleſs they are duly watered in dry Weather.

The twelfth Sort has been found on the Mountains in the North of *England*, but is very common in ſeveral Parts of *Germany*, as alſo on the *Alps* and *Pyrenean* Mountains.

The fourteenth Sort grows in ſeveral Iſlands of the *Archipelago*, and alſo in *Liguria*; It is chiefly found on Hills and Mountains which are moiſt. The Roots of this Sort are as large as ſmall Walnuts, which hang from Dugs after the Manner of *Dropwort*. Theſe Roots, when bruiſed, emit a Smell very like *Spikenard*.

The fifteenth Sort is the true *Spikenard*, which is uſed in Medicine. This grows in great Plenty amongſt the Moſs, on the Tops of the *Alps*, where the Snow lies a great Part of the Year. Theſe Roots are taken up for Uſe in *Auguſt*, when the Leaves decay, at which Time they have the ſtrongeſt Scent.

The eighteenth Sort has alſo knobbed Roots, about as large as Walnuts, which have a Scent ſomewhat like *Spikenard*. This Sort has Leaves like thoſe of the ſmall Valerian, and the Flowers reſemble thoſe of the great Garden Sort, which grow about two Feet high.

All theſe Sorts are very hardy Plants in reſpect to Cold; but they will not live in a dry, light Soil, and an open Situation: Therefore whoever is inclinable to cultivate them, ſhould plant them on a moiſt, loamy Soil, on a North Border, where they may be entirely ſcreened from the Sun; and in very dry Weather they muſt be conſtantly watered, otherwiſe they will not thrive. Theſe Sorts with knobby Roots ſhould not be often tranſplanted; if they are removed every third Year, it will be often enough; but then the Ground between the Roots ſhould be every *Spring* gently dug to looſen it, being careful not to cut or bruiſe the Roots. Theſe Plants uſually flower in *June*, but they ſeldom produce good Seeds.

The ſixteenth Sort is not very common in the *Engliſh* Gardens at preſent. This only differs from the Garden Valerian with white Flowers, in having narrow Leaves; ſo may be propagated in the ſame Manner as the red and white Garden Valerian. It will alſo propagate itſelf by Seeds, if they are permitted to ſcatter in a ſhady Situation, where the Plants will come up without any Care, and may be tranſplanted into large Borders, where they will make an agreeable Variety, and continue a long time in flower.

The nineteenth, twentieth, twentyfirſt and twentyſecond Sorts, were diſcovered by Dr. *Tournefort* in the *Levant*, from whence their Seeds were ſent to *Paris*. Theſe are alſo hardy Plants, which will live in the open Air, and ſhould have a ſhady Situation, and be planted on a moiſt, light Soil.

The twentythird Sort is a Native of the *Pyrenean* Mountains; but is preſerved in the Gardens of the Curious in Botany, for the ſake of Variety. This is a biennial Plant, ſo muſt be permitted to ſcatter its Seeds, for a Supply of young Plants. This Plant ſhould have a moiſt Soil, and a ſhady Situation; where it will thrive, and produce good Seeds; but if the Seeds are not ſown in *Autumn*, they ſeldom grow; ſo that when they ſcatter themſelves, they generally grow better than when they are ſown by Hand. This Sort riſes three Feet high, and has very broad Leaves; but the Flowers being ſmall make no great Appearance; and when their Seeds are ripe the Plants ſoon after periſh.

The twentyfourth and twentyfifth Sorts are annual Plants, which, if once introduced into a Garden, will ſcatter their Seeds, and maintain their Situation. The Seeds of theſe Kinds will diſperſe themſelves to a great Diſtance by the Help of the Down which adheres to them; and often grow on Walls and Buildings, where they are ſtunted and ſmall; but will flower and ſeed, whereby they will become arrant Weeds; notwithſtanding they decay as ſoon as their Seeds are ripe. Theſe two Sorts will grow on any Soil, or in any Situation; but they will thrive beſt on a moiſt Soil, and in a ſhady Situation. Their Seeds muſt be ſown in *Autumn*, otherwiſe they ſeldom ſucceed.

The twentyſixth Sort is a native of the warm Parts of *America*, ſo is a tender Plant, and very rare in *Europe*; for the Seeds will not grow when kept long out of the Ground; but ſhould be ſown in Tubs of Earth abroad; and when the Plants are come up, they may be brought over to *England*. This Sort muſt be preſerved in a Stove, for it is too tender to live in the open Air in this Country. In *Summer* this Plant ſhould have a large Share of free Air, by opening the Glaſſes of the Stove in warm Weather; and muſt be frequently watered, for it grows naturally on low, marſhy Places, and requires a large Share of Water in hot Weather; but in *Winter* it muſt be kept warm, and have but little Water in very cold Weather.

VALERIANA GRÆCA; *vide* Polemonium.

VALERIANELLA, [*q. d.* Small Valerian.] Corn-ſallet, *or* Lamb's-lettuce.

The *Characters* are;

The Leaves grow by Pairs oppoſite on the Branches; the Branches are always divided into two Parts, and appear at the Top like an Umbrello; the Flower conſiſts of one Leaf, which is cut into many Segments, and is ſucceeded by one naked Seed, having no Down adhering to it, in which it differs from the Valerian.

The *Species* are;

1. VALERIANELLA *arvenſis præcox humilis, ſemine compreſſo. Mor. Umb.* Early low Corn-ſallet, with a flat Seed.
2. VALERIANELLA *arvenſis præcox humilis, foliis ſerratis. Tourn.* Early low Corn-ſallet, with ſerrated Leaves.
3. VALERIANELLA *arvenſis ſerotina altior, ſemine turgidiore. Mor. Umb.* Taller late Corn-ſallet, with a turgid Seed.
4. VALERIANELLA *ſemine ſtellato. C. B. P.* Corn-ſallet with a ſtarry Seed.
5. VALERIANELLA *cornucopioides rubra vel Indica. Mor. Umb.* Red or Indian Corn-ſallet, reſembling the Cornucopia.
6. VALERIANELLA *ſemine umbilicato nudo rotundo. Mor. Umb.* Corn-ſallet, with a round naked umbilicated Seed.
7. VALERIANELLA *ſemine umbilicato nudo oblongo. Mor. Umb.* Corn-ſallet, with an oblong naked umbilicated Seed.
8. VALERIANELLA *ſemine umbilicato hirſuto majore. Mor. Umb.* Corn-ſallet, with a larger hairy umbilicated Seed.
9. VALERIANELLA *ſemine umbilicato hirſuto minore. Mor. Umb.* Corn-ſallet, with a ſmaller hairy umbilicated Seed.
10. VALERIANELLA *Cretica, fructu veſicario. Tourn. Cor.* Candy Corn-ſallet, with a bladder'd Fruit.
11. VALERIANELLA *cornucopioides echinata. Inſt. R. H.* Prickly Corn-ſallet, reſembling a Helmet.
12. VALERIANELLA *orientalis, fructu parvo corniculato. Tourn. Cor.* Eaſtern Corn-ſallet, with a ſmall horned Fruit.

The three firſt Sorts are found wild in ſeveral Parts of *England*. The third is often cultivated in Gardens, for Sallets in the *Spring*, though either of the three may be cultivated for the ſame Purpoſe, they being equally good. The Seeds of theſe Plants ſhould be ſown in *Autumn*, ſoon after they are ripe; for if they are kept till *Spring*, the Plants ſeldom come up the ſame *Summer*; the Seeds commonly remaining in the Ground, will come up the ſucceeding *Spring*, notwithſtanding the Place be dug and ſowed with other Seeds, as I have often obſerved.

Theſe Plants will grow in almoſt any Soil or Situation, and require no farther Care, but to keep them clear from Weeds until they are fit for Uſe. They ſhould always be cut while they are young, for if they are grown pretty large, they will become ſtrong and bitter.

The fourth and fifth Sorts are preſerved in Botanick Gardens for Variety, but are not of any Uſe. Theſe may be propagated by ſowing their Seeds in the *Spring*, upon a Bed of dry Earth, where they may remain to flower and ſeed.

Theſe are all annual Plants, which muſt be ſown every Year, or their Seeds permitted to ſcatter upon the Ground, where they will come up, and thrive without any other Culture, than only to clear them from Weeds.

The ſixth, ſeventh, eighth and ninth Sorts are Varieties of the common *Corn-ſallet*, which are preſerved in ſome curious Botanick Gardens, for the ſake of Variety. Theſe are all very hardy Plants, which, if permitted to ſcatter their Seeds, will come up in almoſt any Soil or Situation, and require no other Care but to keep them clear from Weeds. When they are not permitted to ſcatter their Seeds, they ſhould be ſown in *Autumn*, otherwiſe the Seeds will often lie in the Ground till the following *Autumn* before they grow.

The tenth and twelfth Sorts were diſcovered by Dr. *Tournefort* in the *Levant*, from whence he ſent their Seeds to the Royal Garden at *Paris*; which have ſince been communicated to many curious Perſons in *England*. Theſe are very hardy Plants, which may be propagated by Seeds, in the ſame Manner as the other Sorts; and if they are permitted to ſcatter their Seeds, will come up, and require no other Care, but to keep them clear from Weeds.

The eleventh Sort produces Tufts of red Flowers, which are ſhaped like a Helmet, and make a pretty Appearance when blown. This is alſo a hardy Plant, and may be propagated in the ſame Manner as the other Sorts.

VANILLA.

The *Characters* are;

It hath an anomalous Flower, conſiſting of ſix Leaves, five of which are placed in a circular Order, and the other, which occupies the Middle, is concave. The Empalement afterward becomes a horned, ſoft, fleſhy Fruit, filled with very ſmall Seeds.

The *Species* are;

1. VANILLA *flore viridi & albo, fructu nigreſcente. Plum. Nov. Gen.* Vanilla with a green and white Flower, and a blackiſh Fruit.
2. VANILLA *flore violaceo, fructu breviori rubro. Plum. Nov. Gen.* Vanilla, with a Violet-colour'd Flower, and a ſhort red Fruit.
3. VANILLA *flore albo, fructu breviori corallino. Plum. Nov. Gen.* Vanilla, with a white Flower, and a ſhort coralline Fruit.

The Fruit of theſe Plants is called by the *Spaniards* in *America*, *Vanilla*, or *Vinello*, and is much uſed by them to ſcent their *Chocolate*. It is the firſt *Species* here mentioned, which is chiefly eſteemed. This grows plentifully in the *Bay of Campechy*, in the *Weſt-Indies*; where they are uſually ſold for about three Pence each Fruit, *Engliſh* Money.

The other two Sorts are found in ſeveral Parts of *America*, where they always grow in low marſhy Places under Trees, and faſten themſelves to the Trunks of the Trees, and are thereby ſupported. The Fruit of theſe Kinds are rarely uſed, being of little Value; but the other Sort is often brought into *Europe*, and ſold by the Druggiſts.

The Method of gathering and preparing of this Fruit for Uſe is little known to the *Europeans*, being manufactured by the *Indians*, who ſell it very cheap to the *Spaniards*. However, I ſhall ſubjoin an Account which I received from an intelligent Perſon, who had reſided in the *Spaniſh Weſt-Indies* for ſome time; but ſhall firſt deſcribe the Plant, with its Manner of Growth, and how it may be propagated in the warm Parts of *America*.

The Plant which produces the Fruit called *Vanilla* or *Banilla*, by the *Spaniards*, hath a trailing Stem, ſomewhat like common *Ivy*, which faſtens itſelf to whatever Tree grows near it, by ſmall Fibres, which are produced at every Joint, which faſten to the Bark of the Tree, and by which the Plants are often nouriſhed, when they are cut or broken off from the Root a conſiderable Height from the Ground, in like manner as the *Ivy* is often ſeen in *England*. The Leaves are as large as thoſe of the common Laurel, but are not quite ſo thick: theſe are produced alternately at every Joint, (which are ſix or ſeven Inches aſunder) and are of a lively green Colour on the upper Side, but are of a paler Green underneath. The Stems of theſe Plants ſhoot into many Branches, which faſten themſelves alſo to the Branches of the Trees; by which means they riſe to the Height of eighteen or twenty Feet, and ſpread quite over ſome of the ſmaller Trees, to which they are joined. The Flowers are of a greeniſh yellow Colour, mixed with white; which, when fallen, are ſucceeded by the Fruit, which are ſix or ſeven Inches long.

This Sort, which is manufactured, grows not only in the *Bay of Campechy*, but alſo at *Carthagena*, at the *Caraccas*, *Honduras*, *Darien* and *Cayan*; at all which Places, the Fruit are gathered and preſerved: but is rarely found in any of the *Engliſh* Settlements in *America* at preſent, tho' it might be eaſily carried thither and propagated; for the Shoots of theſe Plants are full of Juice, ſo may be eaſily tranſported; becauſe they will continue freſh out of the Ground for ſeveral Months. I had ſome Branches of this Plant, which were gathered by Mr. *Robert Millar* at *Campechy*, and ſent over between Papers by way of Sample: theſe had been at leaſt four Months gathered, when I received them; and upon opening of the Papers, I found the Leaves rotten, with the Moiſture contained in them, and the Paper was alſo periſhed with it; but the Stems appear'd freſh: upon which I planted ſome of them in ſmall Pots, and plunged them into a Hot-bed of Tanners-bark; where they ſoon put out Leaves, and ſent forth Roots from their Joints. But as theſe Plants naturally faſten themſelves to the Stems of the Trees, ſo it is with great Difficulty they are kept alive, when they have not this Aſſiſtance: therefore whoever would preſerve any of theſe Plants in *Europe*, ſhould plant them in Tubs of Earth, near the Stem of ſome vigorous *American* Tree, which requires a Stove, and can bear a great deal of Water; becauſe the Vanilla's muſt be plentifully watered in the *Summer* Seaſon, otherwiſe they will not thrive. They require alſo to be ſhaded from the

Sun by Trees; ſo that if theſe are planted at the Foot of the *Hernandia*, or *Jack-in-a-Box*, whoſe Leaves are very large, and afford a good Shade, they will ſucceed better than when they are expoſed in ſingle Pots alone; and as theſe require the ſame Degree of Heat in *Winter*, ſo they will agree well together.

When theſe Plants are deſigned for Propagation in the warm Parts of *America*, there is nothing more required than to make Cuttings of about three or four Joints in Length, which ſhould be planted cloſe to the Stems of Trees, in low marſhy Places; and to keep down other troubleſome Plants, which if permitted to grow about the Cuttings before they are well rooted, would over-bear and deſtroy them: but after they are eſtabliſhed, and have faſtened their Shoots to the Stems of the Trees, they are not in much Danger of being injured by neighbouring Plants; tho' when the Ground is kept clear from Weeds, the Plants will be much better nouriſhed.

Theſe Plants do not produce Flowers until they are grown ſtrong, ſo that the Inhabitants affirm, that it is ſix or ſeven Years from the Planting to the Time of their bearing Fruit. But when they begin to flower and fruit, they continue for ſeveral Years bearing, and this without any Culture; and as it is a Commodity which bears a good Price, it is well worth Cultivating in ſeveral of the *Engliſh* Settlements, eſpecially as they will grow in moiſt woody Places, where the Land is not clear'd from Timber.

The Method uſed to prepare the Fruit, is, when it turns of a yellow Colour, and begins to open, to gather it and lay it in ſmall Heaps to ferment two or three Days, in the ſame manner as is practiſed for the *Cocoa* or *Chocolate* Pods. Then they ſpread them in the Sun to dry, and when they are about half dried, they flat them with their Hands, and afterwards rub them over with the Oil of *Palma Chriſti*, or of the *Cocoa*: then they expoſe them to the Sun again to dry, and afterward they rub them over with Oil a ſecond time; then they put them in ſmall Bundles, covering them with the Leaves of the *Indian-Reed* to preſerve them.

Theſe Plants produce but one Crop of Fruit in a Year, which is commonly ripe in *May*, fit for gathering; for they do not let them remain on the Plants to be perfectly mature, becauſe then they are not ſo fit for Uſe; but when they are about half changed yellow, they eſteem them better for keeping, than when they are changed to a dark brown Colour; at which time the Fruit ſplits, and ſhews a great Quantity of ſmall Seeds, which are incloſed within it. While the Fruit is green, it affords no remarkable Scent; but as it ripens, it emits a moſt grateful aromatic Odour. When the Fruit begins to open, the Birds attack them, and devour all the Seeds very greedily, but do not eat any other Part of the Fruit.

The Fruit which are brought to *Europe*, are of a dark brown Colour, about ſix Inches long, and ſcarce an Inch broad; are wrinkled on the Outſide, and full of a vaſt Number of black Seeds like Grains of Sand, of a pleaſant Smell, like Balſam of *Peru*.

This Fruit is only uſed in *England*, as an Ingredient in Chocolate, to which it gives a pleaſant Flavour. But the *Spaniſh* Phyſicians in *America* uſe it in Medicine, and eſteem it grateful to the Stomach and Brain, for expelling of Wind, to provoke Urine, to reſiſt Poiſon, and cure the Bite of venomous Animals.

As this Plant is ſo eaſily propagated by Cuttings, it is very ſtrange, that the Inhabitants of *America* ſhould neglect to cultivate it, eſpecially as it is an Ingredient in Chocolate, which is ſo much drank all over *America*; but as the *Engliſh* have in a manner quite neglected the Culture of the *Cocoa*, it is no wonder they ſhould neglect this; ſince the former was cultivated in great Plenty by the *Spaniards* in *Jamaica*, while that Iſland remained in their Poſſeſſion; ſo that the *Engliſh* had an Example before them, if they would have followed it: whereas the *Vanilla* was not found growing there; and therefore it is not to be ſuppoſed, that the Perſons who were ſo indolent, as to quit the Culture of many valuable Plants then growing on the Spot, ſhould be at the Trouble of introducing any new Plants.

VAPORIFEROUS, ſignifies cauſing or producing *Vapours*.

VAPOUR, is by ſome defin'd to be a thin Veſicle of Water, or other humid Matter, fill'd or inflated with Air, which being rarefied to a certain Degree by the Action of Heat, aſcends to a certain Height in the Atmoſphere, where it is ſuſpended till it returns in form of Rain, Snow, or the like.

Some uſe the Term *Vapour* indifferently for all Fumes emitted either from moiſt Bodies, as Fluids of any Kind; or from dry Bodies, as Sulphur, *&c.* But Sir *Iſaac Newton* and other Authors, better diſtinguiſh between humid and dry Fumes, calling the latter *Exhalations*.

VAPOURS, are defin'd by Naturaliſts to be thoſe watry Particles which are ſevered from others by the Motion of the Air, and are carry'd about it in ſeveral Ways, according as the Wind, or Warmneſs of the Air ſerves: They riſe out of the Sea, Rivers, Lakes, and other Waters.

As to their hanging in the Air, we may obſerve, in a hot Day, when there is no Wind ſtirring, ſuch a Company of *Vapours* to riſe out of moiſt Ground, as make thick Fogs, which are ſometimes higher, and ſometimes lower, as the Multitude and Motion of the *Vapours* happen to be. They are to be ſeen as well upon high Grounds as low.

They are eaſily diſſipated by the Wind, and particularly if it be a drying Wind.

The Sun has the ſame Effect upon them; and we commonly ſee, when there are thick Fogs about Sun-riſing, they diſappear a little after it is up.

It is evident, that Fogs do conſiſt of aqueous Particles rarefied, becauſe they mightily bedew every thing that lies open to them. Theſe Particles, being ſoundly moved, muſt needs fly aloft into the Air; but if their Motion be ſomething faint, they play about the Surface of the Earth. For this is agreeable to the Laws of Motion, that ſuch Things as are about the Globe of the Earth, the more they are moved, the more they recede from the Centre of the Earth.

Again, theſe Fogs ariſe out of all Places, mountainous or champain, and continue 'till they are diſpell'd by Wind or Heat; but they continue longeſt in the loweſt Grounds, becauſe thoſe Places are fulleſt of Moiſture, and are not ſo much expos'd to the Winds: But where-ever they be, when the Wind riſes upon them, they are diſſipated and driven about, till we ſee no more of them.

So, in like manner, the Heat of the Sun, by putting them into a brisker Motion, either diſſipates them by Rarefaction, or raiſes them higher, and forms them into Clouds.

And whereas ſometimes the Fogs ſtink, it is not becauſe they come from ſtinking Water, but becauſe the *Vapours* are mixed with ſulphureous Exhalations, which ſmell ſo. Perhaps theſe Exhalations would fly up directly to the Clouds, if there were no Fogs to hold them, and ſo would not affect the Senſe of Smelling; but when they are once entangled and blended with the Fog, they laſt as long as that does.

The Clouds are higher than the Fogs; they hang in the Air, and are carried about in it by the Winds. The Clouds are of various Figures, and ſometimes ſo thin, that the Rays of the Sun paſs through them; but at other times they are thick enough to intercept and obſtruct them: They alſo appear of ſeveral Colours, as, white, red, and ſometimes very dark.

The Thickneſs of the Clouds proceeds from the Cloſeneſs of the vapourous Particles one to another; and their Thinneſs from the Diſtance of thoſe Particles one from another, of which there are ſeveral Cauſes. When they are very thin, they leave ſo many Interſtices, that the Rays of the Sun dart through them in many Places, but are intercepted in others.

As to the Varieties of the Figures of the Clouds, they ariſe from their Plenty of Vapours, and the Influence of the Sun and Wind: For they cannot be variouſly condens'd, rareſy'd, and carry'd about in the Air, but their Figure muſt needs be changed.

To account for the Clouds hanging in the Air, is a Matter of ſome Difficulty.

All the watry Particles, of which they conſiſt, are heavier than Air; and ſo, if there were nothing to hinder them, they would fall to the Earth. But there are two Things that ſeem to keep them up.

1. The Winds which blow from all Parts, under the Region of the Clouds, and bear about with them many lighter Sorts of Bodies; eſpecially if thoſe Bodies contain but a ſmall Quantity of ſolid Matter under a broad Superficies. And thus it is viſible, how eaſy Paper-Kites are kept up by the Wind, when they are mounted pretty high; and ſo the Particles of Water, pretty much rarefied, may eaſily be ſuſpended at that Height.

2. New Exhalations and Vapours are perpetually fuming out of the Earth, and by their moving upwards, prevent the Clouds from deſcending, unleſs the Denſity of the Clouds over-weigh them. Thus we ſee the Vapour of Fire carries lighter Bodies up the Chimney: And Smoke can turn a thin Plate of Iron, artfully plac'd in it, ſo ſtrongly, as to turn about a Spit, and roaſt Meat.

It is a Queſtion among Naturaliſts, whether Clouds and thicker Fogs are compos'd alike? Or whether there be ſomething more in the Clouds.

Some think that Clouds are groſſer than all Fogs; and that they are compos'd of Flakes of Snow, rather than Particles of Water, ſuch as make Fogs.

Others ſay, it is enough to conſider Clouds as a cloſer Sort of Fogs. And indeed the Fogs that hang upon the Tops of very high Hills, appear to People in the Plains, to be all one with Clouds; though thoſe that are at them, perceive nothing but a thick Fog.

There being always many *Vapours* in the Air, though not always viſible, it comes to paſs, that great Dews fall even in clear Weather, and eſpecially in thoſe Countries where it ſeldom rains. For when it happens, that the ſcattered *Vapours* are collected and condens'd together, and forc'd downwards, they muſt needs fall, and bedew Plants and Graſs.

The Time for the falling of the Dew is either before the Riſing of the Sun, or after the Setting of it. But in order to its falling regularly, at thoſe Times, it is neceſſary that the Air be calm; for windy or ſtormy Weather hinders it. But when the Weather is calm, and gentle Breezes are felt from the Weſt about the Time that the Sun ſets; and from the Eaſt about the Riſing of it; it is probable they collect the *Vapours*, and precipitate them, by moderately cooling the Air. And becauſe the Morning Breezes are more general than the Evening ones, therefore the Evening Dews fall only here and there; but the Morning ones ſeldom fail to be univerſal.

It is likewiſe found by Experience, That the Dews are more copious in hotter Countries than in cold; the Reaſon of which ſeems to be this: That the Heat of the Sun does, in the Day-time, raiſe abundance of *Vapours* out of the Water, which *Vapours* are ſo extremely rarefied by the ſame Heat, that they are diſperſed far and wide; but the Cool of the Night brings them together again, and condenſes them to that Degree, that they fall to the Ground, but not in ſuch large Drops as Rain does.

But in colder Countries, where there are frequent Rains, and the *Vapours* are leſs rarefied, moſt of them come down in Rain, and but a ſmall Part turns to Dew.

A certain Author ſays, That in ſome of the hotter Climates, the Earth is without Rain for ſix or ſeven Months together, and is every *Summer* Seaſon ſo much parch'd and dry'd, that there is hardly any Moiſture to be found in it for three or four Feet deep, and during that Time, the Heats are ſo exceſſive, that without the refreſhing Dews of the Nights (which are there very conſiderable) the Plants muſt inevitably periſh; for there is no Moiſture they can have, but from the *Dews*: And yet that Moiſture ſupports the Trees and Plants in a flouriſhing State. Towards the End of the Day, the Leaves contract themſelves, by reaſon of the exceſſive Heat of the Sun; but by the falling of the Dews at Night, they expand and open themſelves; ſo that in the Morning and Forepart of the Day they have a moſt agreeable Verdure. And alſo this Moiſture of the Dews affords ſufficient Nouriſhment to the Plants to bring the Fruits to Perfection.

Dr. *Deſaguliers* has preſented us with the following Attempts, to ſolve the Phænomenon of *Vapours*, Formation of Clouds, and Deſcent of Rain.

He tells us, That though this has been a Subject ſo often treated of, none of the Accounts (that he has met with) ſeem to him to be ſufficient to ſolve all the Circumſtances of it.

That as to what Dr. *Niewentyt* and ſome others have ſaid, that Particles of Fire ſeparated from the Sun-Beams, by adhering to Particles of Water, make up *Moleculæ* or ſmall Bodies, ſpecifically lighter than Air, which therefore by Hydroſtatical Laws, muſt riſe and form Clouds that remain ſuſpended, when they are riſen up to ſuch an Height, that the Air about them is of the ſame ſpecifick Gravity with themſelves.

That Rain is produced by the Separation of the Particles of Fire from thoſe of Water, which laſt being then reſtor'd to their former ſpecifick Gravity, can be no longer ſuſtain'd by the Air; but muſt fall in Drops.

This, ſays Dr. *Deſaguliers*, is liable to ſeveral Objections.

1. It is built upon a Suppoſition, that Fire is a particular Subſtance, or diſtinct Element, which has never yet been prov'd by convincing Experiments and ſufficient Obſervations; and which the Reverend Dr. *Hales* has ſhewn to be an ill-grounded Opinion, in his late Book of *Vegetable Staticks*, and has made it very plain, that thoſe Bodies which had been thought to become heavier by Particles of Fire adhering to them, have, by chymical Operations, been prov'd to be only ſo by the Adheſion of Particles of Air, &c. which he has ſhewn to be *abſorbed* in great Quantities by ſome Bodies, whilſt it is *generated* (or reduced from a fixed to an elaſtick State) by others; nay, that it may be *abſorbed* and *generated* ſucceſſively by the ſame Body under different Circumſtances.

2dly, If the above-mentioned Suppoſition ſhould be allowed, the Difficulty will ſtill remain about the Rain which is produc'd by the Fire's being ſeparated from the Water: For Dr. *Niewentyt* aſcribes this Effect to two different Cauſes.

Firſt, to Condenſation; for he ſays; "That when contrary Winds blow againſt the ſame Cloud, and drive the watry Particles together, the Fire that adher'd to them gets looſe, and they (becoming then ſpecifically heavier) precipitate and fall down in Rain." And in the very next *Section* he aſcribes it to Rarefaction; in that he ſays; "When a Wind blowing obliquely upwards, cauſes a Cloud to riſe in a thinner Air, (*i. e.* ſpecifically lighter than itſelf) the Fire, which by ſticking to the Particles of Water render'd them lighter, extricates itſelf from them, and aſcending by its Lightneſs, the Water will become too heavy, not only to remain in this thin and light Air, but even in a thicker and heavier near the Earth, and ſo will be turn'd into a deſcending Dew, Miſt, or Rain, or Snow, or the like, according as the watry *Vapours* are either rarefied or compreſſed."

To this Dr. *Deſaguliers* anſwers; That the firſt of theſe Cauſes of Rain is contrary to Experience; for when two contrary Winds blow againſt each other, over any Place of the Earth, the Barometer always riſes, and we have fair Weather. For then (as Dr. *Halley* ſays, in *Philoſophical Tranſactions*, Nº 183.) the Air being accumulated above, becomes ſpecifically heavier about the Clouds, which (inſtead of falling into Rain, as Dr. *Niewentyt* ſuppoſes) aſcend up into ſuch a Part of the Atmoſphere, as has the Air of the ſame ſpecifick Gravity with themſelves.

If the falling of Rain might be attributed to the ſecond of theſe Cauſes, then every Time a Cloud is encompaſſed with Air ſpecifically lighter than itſelf, (whether it be when by the blowing away ſome of the ſuperior Air, that which is about the Cloud becomes rarer, as it is leſs compreſs'd, or by the Cloud being driven upwards;) Rain muſt neceſſarily follow; whereas one may often ſee Clouds riſe and fall without Rain, even when the Barometer ſhews the Weight of the Air to be altered.

For that happens only, when by the great Diminution of the ſpecifick Gravity of the Air about the Cloud, it has a great Way to fall; in which Caſe the Reſiſtance of the Air, which increaſes as the Velocity of the deſcending Cloud, cauſes the floating Particles of Water to come within the Power of each other's Attraction, and form ſuch big Drops, as being ſpecifically heavier than any Air, muſt fall in Rain.

No gentle Deſcent of a Cloud; but only an accelerated Motion downwards, produces Rain.

He explains himſelf, that by this he does not mean, *That the quick Deſcent of a Cloud is the only Cauſe of Rain; becauſe the Shock from a Flaſh of Lightning, and the ſudden Return of the Air, after the* Vacuum *made by the Flaſh, will condenſe the floating* Vapour *into Water; and alſo the ſame Cloud which in the free Air might be carried horizontally, without being turned into Rain, meeting with a high Hill in the Way, will be condenſed, and fall in Drops; eſpecially if in the Day-time it be driven by the Wind out of the Sun-ſhine, againſt the ſhaded Side of a Mountain.*

Beſides all this, if Particles of Fire were join'd with thoſe of Water to raiſe them up, thoſe igneous Particles muſt be at leaſt a thouſand times greater in Bulk than the watry ones, ſo that a Perſon, who at the Top of an Hill, has his Hands and Face in a Cloud, muſt feel a very ſenſible Warmth, by touching a much greater Surface of Fire than Water in the Cloud, and afterwards find the Rain produc'd by that *Vapour* ſenſibly colder; whereas the contrary is prov'd by our Senſes, the Tops of Hills, though in the Clouds, being much colder than the Rain at the Bottom.

There is another Opinion concerning the Riſe of *Vapours*, namely; That tho' Water be ſpecifically heavier than Air, yet if its Surface be increas'd, by very much diminiſhing the Bulk of its Particles, when once rais'd, it cannot eaſily fall; becauſe the Weight of each Particle diminiſhes, as the Cube Root of its Diameter, and the Surface to which the Air reſiſts, only as the Square Root of the Diameter: That we ſee this in the Duſt in *Summer*, and in *Menſtruums* that ſuſtain Metals diſſolv'd, which are ſpecifically heavier than the *Menſtruums*.

But this will not explain the Phænomenon; becauſe though the Increaſe of Surface (the Weight remaining the ſame) will, in a great meaſure, hinder (or rather retard) the Deſcent of ſmall Bodies, moving in the Air, by reaſon of its great Reſiſtance to ſo large a Surface; it will for the ſame Reaſon alſo hinder the Aſcent.

For the Riſe of Duſt is owing to the Motion of Animals Feet in it, or to the Wind; whereas *Vapours* riſe in cold Weather, as well as windy; neither do they, like the Duſt, always fall to the Ground, when the Wind ceaſes to blow.

The third Opinion, and which is moſt commonly receiv'd, is, that by the Action of the Sun on the Water, ſmall Particles thereof are form'd into hollow Spherules, fill'd with an *Aura*, or finer Air highly rarefied, ſo as to become ſpecifically lighter than common Air, and conſequently that they muſt riſe in it by Hydroſtatical Laws.

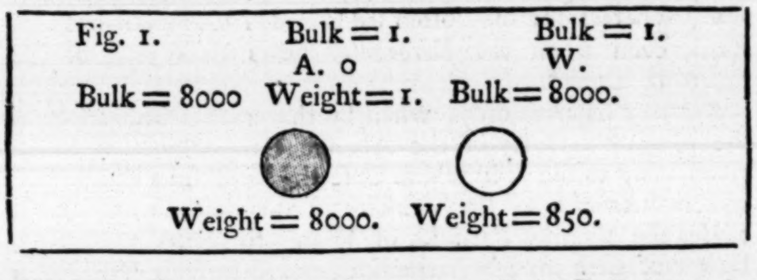
As for Example: If a Particle of Water, as it becomes a hollow Sphere, be only increaſed ten times in Diameter, its Bulk will be increas'd a thouſand times; therefore, it will be ſpecifically lighter than common Water, whoſe ſpecifick Gravity is to that of Air as 850 to 1; then, if the Denſity of the *Aura*, or Spirit within the little Shell, be ſuppoſed 9 times leſs than that of Air, or as 95 to 850, that ſpecifick Gravity of the Shell, and its Contents will be to that of Air, as 945 to 1000; therefore ſuch an aqueous Bubble muſt riſe till it come to an *Æquilibrium* in Air, whoſe Denſity is to the Denſity of that in which it began to riſe, as 850 to 945, or nearly.

But it appears by Experiments, that Air rarefied by an Heat, which makes a Retort red hot, is only increaſed in Bulk, or dilated 3 times: by the Heat of boiling Water only $\frac{10}{14}$, or near two Thirds; and by the Heat of human Body, (ſuch as will raiſe *Vapours* plentifully) only $\frac{10}{39}$, or about one Fourth.

He owns his Objection may be anſwered, by ſuppoſing the Spherule of Water to be more increas'd in Diameter; as for Example, 20 Times; becauſe then if it be filled with Air only $\frac{1}{4}$ rarer than common Air, it will be ſpecifically lighter, and capable of riſing to a conſiderable Height.

To give this Solution all its Force, let it be expreſſed in Numbers. Let A and W *(Fig. 1.)* repreſent a Particle of Air, and one of Water of equal Bulk, then will the Weight of A be to the Weight of W as 1 to 850, their Bulks being equal. If the Particle of Water be blown up in a Bubble (W) of 20 times its Diameter, then will its Bulk be to its Weight as 8000 to 850, whilſt a Sphere of Air (A) of the ſame Bigneſs, has its Weight as well as Bulk equal to 8000: Now, if an Air or *Aura*, $\frac{1}{4}$ rarer than common Air, be ſuppoſed within the watry Bubble to keep it blown, it will be the ſame as if $\frac{3}{4}$ of the Air of (A) was carryed into (W), and then the Weight of (W) would be increaſed by the Number 6000; ſo that the Shell of Water being in Bulk 8000, would be in Weight 850+6000=6850, whilſt an equal Bulk of Air weighed 8000, and conſequently the watry Bubble would riſe 'till it came to an Air, whoſe Denſity is to that of the Air, next to the Surface of the exhaling Water, as 6850, to 8000.

Fig. 1.



This is the ſtrongeſt Way of ſtating the Hypotheſis; but to ſupport it, the following *Queries* muſt be anſwered.

Query 1. How comes the *Aura* or Air in the Bubbles to be ſpecifically lighter than that without them, ſince the Sun's Rays, which act upon the Water, are equally denſe all over its Surface?

Query. 2. If it could be poſſible for a rarer Air to be ſeparated from the denſer ambient Air, to blow up the Bubbles (as Bubbles of ſoap'd Water are blown up by warm Air from the Lungs, whilſt the ambient Air is colder and denſer) what would hinder that cold Air, by its greater Preſſure, from reducing the Bubbles to a leſs Bulk, and greater ſpecifick Gravity than the Air, eſpecially ſince Cold can be communicated thro' ſuch thin Shells, and the Tenacity of common Water is very ſmall, when compared to that of ſoaped Water, whoſe Bubbles, notwithſtanding that Tenacity, are ſoon deſtroyed by the Preſſure of the outward Air, as the Air within them cools?

Query 3. If we ſhould grant all the reſt of the Suppoſition, yet this Difficulty will remain: If Clouds are made up of hollow Shells of Water fill'd with Air, why do not thoſe Clouds always expand when the ambient Air is rarefied, and preſſes leſs than it did before, and alſo ſuffer a Condenſation, as the ambient Air is condenſ'd by the Accumulation of the ſuperior Air?

If this Condenſation and Rarefaction ſhould happen to Clouds, they would always continue at the ſame Height, contrary to Obſervation, and we ſhould never have any Rain.

From all this it follows, that the Condenſation and Rarefaction of the Vapours, *which make Clouds, muſt depend upon another Principle, than the Condenſation and Rarefaction of the Air; and that there is ſuch a Principle will be hereafter ſhewn.*

Lemma. *The Particles of all Fluids have a repellent Force.*

Fluids are elaſtick or unelaſtick: The elaſtick Fluids have their Denſity proportionable to their Compreſſion, and Sir *Iſaac Newton* has demonſtrated (*Princip. Lib.* 2. *Sect.* 5.) that they conſiſt of Parts that repel each other from their reſpective Centers.

Unelaſtick Fluids, like Mercury, Water, and other Liquors, are, by Experiments, found to be incompreſſible; for Water, in the *Florentine* Experiment, could not, by any Force be compreſs'd into leſs Room, but ooz'd like Dew through the Pores of the hollow golden Ball, in which it was confin'd, when a Force was apply'd to preſs the Ball out of its ſpherical, into a leſs capacious Figure.

Now this Property of Water, and other Liquors, muſt be entirely owing to the centrifugal Force of its Parts, and not its want of Vacuity; ſince Salts may be imbib'd by Water without increaſing its Bulk, as appears by the Increaſe of its ſpecifick Gravity.

So Metals, which (ſingly) have a certain ſpecifick Gravity, beyond which they cannot be condenſ'd, will yet receive each other in their Interſtices, ſo as to make a Compound ſpecifically heavier than the moſt ponderous of them; as is experienc'd in the Mixture of Copper and Tin.

Scholium. By increaſing the repellent Force of the Particles, an unelaſtick or incompreſſible Fluid, may become elaſtick; or a ſolid (at leaſt a great Part of it) may be chang'd into an elaſtick Fluid; and, *vice verſa*, by diminiſhing the repellent Force, an elaſtick Fluid may be reduc'd to an unelaſtick Fluid or to a Solid.

That the Particles of Quickſilver, Water, and other Liquors, are likewiſe endued with an attractive Force, is evident from thoſe Subſtances running into Drops in an exhauſted Receiver, as well as in the Air, and likewiſe their adhering to other Bodies.

The Attraction and Repulſion exert their Forces differently: The Attraction only acts upon the Particles which are in Contact, or very near it; in which Caſe it overcomes the Repulſion ſo far, as to render that Fluid unelaſtick, which otherwiſe would be ſo; but it does not wholly deſtroy the Repulſion of the Parts of the Fluid; becauſe it is on account of that Repulſion that the Fluid is then incompreſſible.

When by Heat or Fermentation (or any other Cauſe, if there be any) the Particles are ſeparated from the Contact, the Repulſion grows ſtronger, and the Particles exert that Force at great Diſtances, ſo that the ſame Body ſhall be expanded into a very large Space by becoming fluid, and may ſometimes take up more Room than it did in a ſolid or incompreſſible Fluid. (See the *Queries* at the End of Sir *Iſaac Newton's Opticks.*) Thus is Water by boiling and leſs Degrees of Heat, chang'd into an elaſtick *Vapour*, rare enough to riſe in Air; and Oils and Quickſilver in Diſtillation, made to riſe in a very rare Medium; ſuch as remains in the red-hot Retort and ſulphureous Steams will riſe even in an exhauſted Receiver, as the Matter of the *Aurora Borealis* does in the thinner Part of our Atmoſphere.

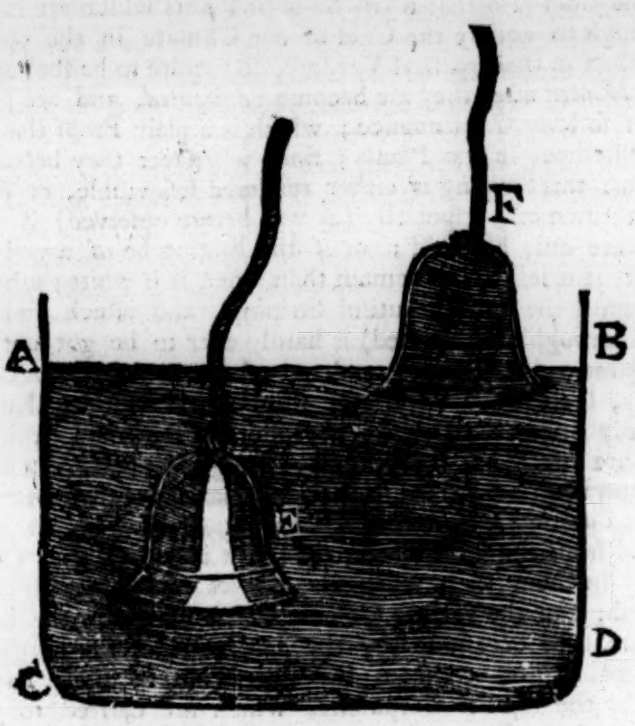
If *Aqua-fortis* be poured on Quickſilver, a reddiſh Fume will riſe, much lighter than common Air: So alſo will Fumes ariſe from Fileings of Metals, from Vegetables, when they ferment by Putrefaction (as the Reverend Dr. *Hales* has ſhewn;) ſeveral ſolid Subſtances, by Diſtilling as well as Fermentation, will generate permanent Air.

That Heat will add Elaſticity to Fluids is evident, from numberleſs Experiments, eſpecially from Diſtilling and Chymiſtry: But what is needful to be conſidered here, is only that it acts more powerfully on Water than common Air; for the ſame Heat which rarefies the Air only $\frac{2}{3}$, will rarefy Water very near 14000 times, changing it into Steam or *Vapour* as it boils; and in *Winter*, that ſmall Degree of Heat, which, in reſpect to our Bodies appears cold, will raiſe a Steam or *Vapour* from Water at the ſame Time that it condenſes Air.

By a great many Obſervations made by Mr. *Henry Beighton*, F. R. S. and Dr. *J. T. Deſaguliers*, to raiſe Water by Fire; according to Mr. *Newcomen*'s Improvement of it, they found that the Water, by boiling, was expanded 14000 times, to generate Steam as ſtrong (*i. e.* as elaſtick) as common Air, which therefore muſt be near 16 $\frac{1}{2}$ times ſpecifically lighter.

And it is plain that this Steam is not made of the Air extricated out of the Water, becauſe it is condens'd again into Water by a Jet of cold Water ſpouting into it; and the little Quantity of Air that comes out of the injected Water muſt be diſcharg'd at every Stroke, otherwiſe the Engine will not work well.

EXPERIMENT.



ABCD repreſent a pretty large Veſſel of Water, which muſt be ſet on the Fire to boil. In this Veſſel muſt be ſuſpended the Glaſs Bell E, made heavy enough to ſink in Water; but put in, in ſuch a manner, that it be fill'd with Water when upright, without any Bubbles of Air at its Crown within, the Crown being all under Water.

As the Water boils, the Bell will by Degrees be emptied of its Water, being preſs'd down by the Steam which riſes above the Water in the Bell; but as that Steam has the Appearance of Air, in order to know whether it be Air or not, take the Veſſel off the Fire, and draw up the Bell by a String faſten'd to its Knob at Top; then as the Steam condenſes by the cold Air on the Outſide of the Bell, the Water will riſe up into the Bell a F, quite to the Top, without any Bubble above it, which ſhews that the Steam that kept out the Water was not Air.

N. B. *This Experiment ſucceeds beſt when the Water has been firſt purged of Air by boiling, and the Air-Pump.*

We know by ſeveral Experiments made on the Fire-Engine, (in Captain *Savory*'s Way, where the Steam is made to preſs immediately on the Water) that Steam will drive away Air, and that in Proportion to its Heat; tho' in the open Air, it floats, and riſes in it like Smoak.

Now, if the Particles of Water turn'd into *Steam* or *Vapour*, repel each other ſtrongly, and repel Air more than they repel each other, Aggregates of ſuch Particles made up of *Vapour* and *Vacuity*, may riſe in Air of different Denſities, according to their own Denſity dependant on their Degree of Heat, without having Recourſe to imaginary Bubbles, form'd in a manner only ſuppos'd, and not prov'd; as has been already ſhewn.

Indeed he owns, that if the watry Particles had no repellent Force, they muſt precipitate in the ſame manner that Duſt will do after it has been rais'd up: But there are too many Obſervations and Experiments to leave any Doubt of the Exiſtence of the repellent Force above-mention'd.

And that he cannot ſhew, by any Experiment, how big the Moleculæ *of Vapour muſt be which will exclude Air from their Interſtices; nor that theſe* Moleculæ *do vary in Proportion to the Degree of Heat by an Increaſe of repellent Force in each watery Particle; or by a farther Diviſion of the Particles ſtill leſs: But in the general, we may reaſonably affirm, that the Rarety of the* Vapour *is proportionable to the Degree of its Heat, as it happens in other Fluids: (See Philoſophical Tranſactions,* Numb. 270.) *And though the different Degrees of the Air's Rarefaction are alſo proportionable to the Heat, yet the ſame Degree of Heat rarefies* Vapour *much more than* Air.

Now to ſhew that what has been ſaid will account for the Riſe of *Vapours* and Formation of *Clouds*, we muſt only conſider, whether that Degree of Heat which is known to rareſy Water 14000 times, being compared with ſeveral of thoſe Degree of Heat in *Summer*, *Autumn*, and *Winter*, which are capable of raiſing Exhalations from Water or Ice; the Rarety of the *Vapours* (being conſider'd the Degree of Heat) will appear to be ſuch, that the *Vapour* will riſe high enough in *Winter*, and not too high in *Summer*, to agree with the known Phænomena.

That the Effects are adequate to the Cauſes in this Caſe, he thinks may be made out in the following Manner, *viz.*

The Heat of boiling Water, according to Sir *Iſaac Newton*'s Table (*Philoſoph. Tranſact.* Numb. 270. is 34, the mean Heat of *Summer* 5, the mean Heat of *Spring* or *Autumn* 3, and the leaſt Degree of Heat at which *Vapours* riſe in *Winter* (*alias* the mean Heat of *Winter*) is 2.

The Rarety of *Vapour* proportionable to theſe 4 Degrees of Heat, is 14000, 2058, 1235, and 823.

The Rarety of Air is in *Summer* 900, in *Spring* or *Autumn* 850, and in *Winter* 800.

The Denſity of Water, compar'd with the above-mention'd Denſities, being inverſely as 1. to the 'fore-mention'd four Numbers.

The Heights above the Earth to which the *Vapours* will ariſe, and at which they will be in *Equilibrio*, in an Air of the ſame Denſity with themſelves, will vary according to the Rarety of the *Vapour* depending upon the Heat of the Seaſon.

For the *Vapour* which is rais'd by the *Winter*'s Heat expreſs'd by the Number 2, when the Rarety of the Air is 800, will riſe to (and ſettle at) an Height of about the ſixth Part of a Mile, when the *Barometer* is above 30 Inches high.

But if the Heat be greater, then the *Vapours* will riſe higher, and pretty much higher if the Sun ſhines, tho' in froſty Weather, the *Barometer* then being very high.

If the *Barometer* falls, and thereby brings the Place of *Equilibrium* (for *Vapours* rais'd by the Heat 2,) nearer the Earth, then alſo will the Heat be increas'd, the *Vapour* more rarefied, and conſequently the new Place of *Equilibrium* ſufficiently high.

It is to be obſerv'd that, in *Winter*, when the Heat is only equal to 2, the Air is dens'd cloſe to the Earth, which has not any Heat ſufficient to rarefy it near the Ground, as happens in warm Weather; therefore the *Vapour* will riſe gradually in an Air whoſe Denſity decreaſes continually from the Earth upwards; neither will the *Vapour* be hinder'd of its full Riſe by any Condenſation from a greater Cold of the ambient Air, the Air being then as cold next to the Ground, where the *Vapour* begins to riſe, as it is at any Height from the Earth.

The *Vapour* which is rais'd by the Heat of the *Spring* or *Autumn*, expreſs'd by Number 3, will riſe to the Height of 3 $\frac{1}{2}$ Miles when the *Barometer* is at 30, and the Air's Rarety is 850. But then as the Air is hotter near the Ground than at the Height of half a Mile or a Mile, the *Vapour* will condenſe as it riſes; and as the Air, when the Earth is heated, is rather near the Ground than at ſome Height from it, the Place for *Equilibrium* will, upon theſe two Accounts, be brought much lower than otherwiſe it would be: As for Example, To the Height of about a Mile; which will agree with *Phænomena.*

In *Summer*, the two Cauſes above-mention'd increaſing, the *Vapour* rais'd by the Heat 5, (whoſe Place of *Equilibrium* would be 5 $\frac{1}{2}$ Miles high, if the *Vapour*, after it began to riſe, was not condens'd by cooling, and the Air was dens'd cloſe to the Earth) will ſettle at the Height of about 1 $\frac{1}{2}$ or 2 Miles, which is alſo agreeable to *Phænomena.*

Laſtly, As the Denſity and Rarety of the *Vapour* is chiefly owing to its Degree of Heat, and in a ſmall meaſure, to the increas'd or diminiſh'd Preſſure of the circumambient Air, when it is not confin'd; and the Denſity and Rarety of the Air is chiefly owing to the increas'd or diminiſh'd Preſſure, by the Accumulation or Exhauſtion of ſuperior Air, whilſt Heat and Cold alter its Denſity in much leſs Proportion: The Clouds made of the *Vapours* above-mentioned, inſtead of conforming themſelves to the alter'd Denſity of the ambient Air, will riſe when it is condens'd, and ſink when it is rarefied; and alſo riſe or ſink, when the Preſſure of the Air is not alter'd, and its Denſity very little chang'd, by their own Dilatation, owing to Heat or Cold: As may be often obſerv'd, by ſeeing them change their Height conſiderably, whilſt the *Barometer* continues exactly at the ſame Degree, and the Liquor of the *Thermometer* riſe or falls very little, and ſometimes not at all.

As for the Manner how Clouds are chang'd into Rain, it has been hinted at the Beginning of this Article; but, for farther Satisfaction, let the Reader have Recourſe to Dr.

Halley's Account of it in the *Philoſophical Tranſactions*, N° 183, which Dr. *Deſaguliers* ſays he has always found agreeable to the *Phænomena*.

He adds, That ſince he had, for Brevity ſake, only mentioned at what Height from the Surface of the Earth *Vapours* of different Denſities will come to an *Equilibrium*, without giving a Reaſon for ſettling the Place of *Equilibrium*, at whoſe Heights he thought it proper here to give the Method by which they may be found, *viz.*

As the *Vapours* will ſettle and riſe where the Air is of the ſame Denſity with themſelves, it is only required to find the Denſity of the Air at any Diſtance from the Earth at ſeveral Heights of the *Barometer*, which may be deduced from Dr. *Halley*'s two Tables, *Philoſophical Tranſactions* N° 386. (the firſt ſhewing the Altitudes to given Heights of the *Mercury*, and the ſecond the Heights of the *Mercury* again at given Altitudes) and knowing the Degree of Heat by the *Thermometer*, becauſe the Denſity of the *Vapour* depends upon the Degree of Heat of the Seaſon, provided that proper Allowances be made for the great Rarefaction of the Air near the Earth in hot and dry Weather, and the Condenſation of the *Vapours* in their Riſe, by reaſon of the Air being colder at a little Height above the Earth than juſt at the Surface of it.

The Quantity of *Vapour* raiſed from the Sea by the Warmth of the Sun, is far greater than one would imagine. Dr. *Halley* has attempted to eſtimate it.

In an Experiment made with that View, and deſcribed in the *Philoſophical Tranſactions*, he found that a Quantity of Water no warmer than Air in *Summer*, loſt in *Vapour*, in the Space of two Hours, no leſs than $\frac{1}{53}$ Part of an Inch in Depth: Now for $\frac{1}{53}$ in two Hours, taking for the eaſier Calculation, $\frac{1}{60}$ in the twelve Hours that the Sun is up each Day, it will riſe $\frac{1}{10}$ of an Inch from the Surface of the Sea.

On this Suppoſition, every ten ſquare Inches of the Surface of the Water yield in *Vapour*, *per Diem*, a cubick Inch of Water; four feet ſquare, a Gallon; a Mile ſquare, 6914 Tuns: A ſquare Degree, ſuppoſed of 60 *Engliſh* Miles, will evaporate 33 Millions of Tuns; and if the *Mediterranean* Sea be eſtimated at 410 Degrees long, and 4 broad, Allowances being made for the Places where it is broader, by thoſe where it is narrower, there will be 160 ſquare Degrees at Sea; and conſequently the whole *Mediterranean* muſt loſe in *Vapour*, in a *Summer*'s Day, at leaſt 5280 Millions of Tuns.

In this Quantity of *Vapour*, though very great, are only the Remains of another Cauſe, which cannot be reduced to Rule; that is, the Winds, whereby the Surface of the Water is licked up, ſometimes faſter than it exhales by the Heat of the Sun; as it is well known to thoſe who have conſider'd thoſe drying Winds.

For the Manner wherein *Vapours* are raiſed, ſee more in *Dew*, *Rain*, *Heat*, *Cold*, and *Barometer*.

For the Effect of *Vapours* in Formation of Springs, ſee *Springs*, &c.

VARIEGATED, ſignifies ſtreak'd or diverſified with ſeveral Colours. There are now a great Variety of Plants in the Gardens of the Curious, whoſe Leaves are *variegated* with yellow or white. Thoſe which are ſpotted with either of theſe Colours in the Middle of their Leaves, are called *blotch'd* (in the Gardener's Term); but thoſe whoſe Leaves are edged with theſe Colours, are called *ſtrip'd* Plants: Thoſe Plants whoſe Leaves are blotch'd, are generally ſubject to become plain, when planted in a good Soil, or at leaſt in the growing Seaſon, will have but ſmall Appearance of the two Colours; but thoſe which have edged Leaves, do rarely become plain again, eſpecially if the Edging is broad, and goes quite thro' the Leaves; tho' theſe do not appear ſo finely *variegated* in the growing Seaſon, as they do the other Parts of the Year.

All the different Sorts of *Variegation* in Plants were at firſt accidental, being no more than a Diſtemper in the Plant; which being obſerved, has been cheriſhed by impoveriſhing the Soil in which they grow, by which Method their Stripes are rendered more laſting and beautiful. But whatever ſome Perſons have affirmed of ſtriping Plants by Art, I could never obſerve it done by any, unleſs in woody Shrubs and Trees, which may be *variegated* by putting in a Bud or Graft taken from a *variegated* Plant, where altho' the Buds ſhould not grow, yet if they keep freſh but eight or ten Days, they will many times communicate their gilded *Miaſma* to the Sap of the Trees into which they were budded; ſo that in a ſhort Time after, it has appeared very viſible in the next adjoining Leaves, and has been afterwards ſpread over the greateſt Part of the Tree: But in ſuch Plants which are herbaceous, where this Operation cannot be performed, there is no Way yet aſcertained whereby this Striping can be effected by Art.

In ſome Sorts of Plants this Diſtemper is often communicated to the Seeds; ſo that from thoſe Seeds gathered from *variegated* Plants, there will conſtantly be ſome *variegated* Plants produced; as in the *Strip'd-wing Pea*, the *Greater Maple*, &c. ſo that theſe may be conſtantly propagated that Way.

That this Striping proceeds from the Weakneſs of Plants, is very evident, ſince it is always obſerved, that whenever Plants do alter thus in the Colour of their Leaves, they do not grow ſo large as before, nor are they ſo capable to endure the Cold; ſo that many Sorts of Plants which are hardy enough to endure the Cold of our Climate in the open Air, when in their natural Verdure, do require to be ſhelter'd in the *Winter* after they are become *variegated*, and are ſeldom of ſo long Continuance; which is a plain Proof that it is a Diſtemper in the Plants; ſince whenever they become vigorous, this Striping is either rendered leſs viſible, or entirely thrown off; eſpecially (as was before obſerved) if the Plants are only blotch'd; or if the Edging be of a yellow Colour, it is leſs apt to remain than when it is white; which is eſteemed the moſt beautiful Striping, and which (when once thoroughly eſtabliſhed) is hardly ever to be got out of the Plants again, ſo as to render the Leaves entirely green.

Nay, ſuch is the Venom of this morbid Matter, that it not only tinges the Leaves, but alſo the Bark and Fruit of Trees are infected by it; as in the Orange, Pear, &c. whoſe Bark and Fruit are ſtriped in the ſame Manner as their Leaves.

The different Colours which appear in Flowers do alſo proceed from the ſame Cauſe, though it is generally in a leſs Degree in them than when the Leaves and Branches are infected: For the various Colours which we ſee in the ſame Flowers, are occaſioned by the Separation of the nutritive Juice of Plants, or from the Alteration of their Parts, whereby the ſmaller Corpuſcles, which are carried to the Surface of the Flower-leaves, are of different Forms, and do thereby reflect the Rays of Light in different Proportions. In order to underſtand this, it may not be improper to ſay ſomething concerning the Phænomenon of *Colours*, as it hath been diſcovered by the late excellent Philoſopher Sir *Iſaac Newton*.

1. *Colour* may be conſidered two Ways. (1.) As a Quality reſiding in the Body, that is ſaid to be ſo and ſo colour'd, or which doth modify the Light after ſuch and ſuch a Manner: Or, (2.) As more properly the Light itſelf, which being ſo modified, ſhines upon the Organ of Sight, and produces that Senſation we call *Colour*.

2. *Colour* is defined to be a Property inherent in Light, whereby, according to the different Sizes or Magnitudes of its Parts, it excites different Vibrations in the Fibres of the Optick Nerve; which being propagated to the *Senſorium*, affects the Mind with different Senſations.

3. Again: *Colour* may be defined a Senſation of the Soul, excited by the Application of Light to the *Retina* of the Eye; and different, as the Light differs in the Degree of its Refrangibility, and the Magnitude of its component Parts.

4. According to the firſt Definition, Light is the *Subject* of *Colour*; according to the latter, it is the *Agent*.

5. So then, *Light* ſometimes ſignifies that Senſation occaſioned in the Mind by the View of luminous Bodies; ſometimes that Property in thoſe Bodies, whereby they are fitted to excite thoſe Senſations in us.

6. Various are the Opinions of ancient and modern Authors, and of the ſeveral Sects of Philoſophers, with regard to the Nature and Origin of the Phænomenon *Colour*.

7. The *Peripateticks* aſſert *Colours* to be real Qualities, and inherent in the coloured Bodies, and ſuppoſe that *Light* doth only diſcover them, but not any Way affect their Production.

8. *Plato* thought *Colour* to be a Kind of Flame, conſiſting of moſt minute Particles, very congruous to the Pores of the Eye, and darted againſt it from the Object.

9. Some Moderns will have *Colour* to be a Kind of internal Light, of the more lucid Parts of the Object darkened, and conſequently altered by the various Mixtures of the leſs luminous Parts.

10. Others, as did ſome of the ancient Atomiſts, maintain *Colour* not to be a lucid Stream, but a corporeal Effluvium iſſuing out of the coloured Body.

11. Others account for all *Colours* out of the various Mixture of Light and Darkneſs: And the Chymiſts will have it ſometimes ariſe from the Sulphur, and ſometimes from the Salt that is in Bodies; and ſome alſo from the third Hypoſtatick Principle, *i. e. Mercury*.

12. The moſt popular Opinion is that of the Followers of *Ariſtotle*, who maintain, that *Colour* is a Property inherent in

the coloured Body, and that it exiſts without any Dependance on Light.

13. The *Carteſians*, who make the Senſation of Light to be the Impulſe made on the Eye by certain ſolid, but very minute Globules, eaſily permeating the Pores of the Air and diaphonous Bodies: Theſe derive *Colour* from the various Proportion of the direct Progreſs or Motion of theſe Globules, to their Circumrotation or Motion round their own Centres; by which Means they are qualified to ſtrike the Optick Nerve, after diſtinct and divers Manners, and ſo do produce the Perception of various *Colours*.

14. They own, that as the *coloured* Body is not immediately apply'd to the Organ, to occaſion the Senſation, and as no Body can affect the Senſe but by immediate Contact, the *coloured* Body does not excite the Senſation of itſelf, or contribute any Thing to it, otherwiſe than by moving ſome interpoſed Medium, and by that the Organ of Sight.

15. They add, That as it is found that Bodies do not affect the Senſe in the Dark, and that Light only occaſions the Senſation of *Colour*, by moving the Organ; and that *coloured* Bodies are no farther concerned, than in reflecting the Light in a certain Modification; the Difference in *Colours*, according to them, ariſes in a Difference in the Texture of their Parts, by which they are diſpoſed to reflect the Light with this or that Modification.

16. Dr. *Hook*, in his *Micographia*, ſays, The Phantaſm of *Colours* is cauſed by the Senſation of the oblique or uneven Pulſe of Light, and that this is capable of no more Varieties than two, which ariſe from the two Sides of the oblique Pulſe; ſo that there is in Reality but two ſimple *Colours*, *Yellow* and *Blue*; from the Mixture of which, and a due Proportion of Black and White (that is, Darkneſs and Light) all *Colours* may be produced.

17. But this Phænomenon of Nature, *Colour*, having long perplexed Philoſophers to account for the Diſcoveries relating thereto, the incomparable Sir *Iſaac Newton* found, by two Experiments on Priſms, that there is a great Deformity in the Rays of Light, and that hereby the *Origin of Colours* may be unfolded: The Doctrine of *Colours* therefore, according to his Notion and Experiments, are contained in the following Propoſitions:

1. That Light conſiſts of an infinite Number of Rays, right-lined and parallel; but of different Degrees of Refrangibility, when meeting with a different Medium.
2. Each Ray, according to its Degree of Refrangibility, when ſo refracted, appears to the Eye of a different Colour.
3. The leaſt refrangible Rays appear of a *deep Scarlet* Colour; the moſt refrangible appear of a *Violet Blue*: The intermediate proceeding from *Scarlet* to *Yellowiſh*, then to *light Green*, and ſo to *Blue*.
4. The *Colours* ariſing from the different Degrees of Refrangibility of Light, are not only the more noted *Colours* of *Red*, *Yellow*, *Green*, *Blue*; but alſo all the intermediate *Colours* of *Red* to *Yellow*, of *Yellow* to *Green*, &c.
5. *Whiteneſs*, (ſuch as the Sun's Light appears) containing all thoſe Degrees of Refrangibility, is conſequently made up of all the abovementioned *Colours*.
6. *Simple* or *Homogeneal Colours*, are ſuch as are produced by *Homogeneal* Lights or Rays, which have the ſame Degree of Refrangibility; and mix'd *Colours* are ſuch as are produced by Rays of different Refrangibility.
7. Rays of the ſame Refrangibility produce the ſame *Colour*; which *Colour* is not alterable by repeated Refractions, but only made more ſtrong or faint, as the Rays are united or ſcattered.
8. All Bodies appear of this or that *Colour*, according as their Surfaces are adapted to reflect only the Rays of ſuch a *Colour*, or (at leaſt) in more Plenty than the reſt.

But to explain theſe Things farther:

It is found by Experience, that Rays or Beams of Light, are compoſed of Particles very heterogeneous or diſſimilar to each other; *i. e.* ſome of them, as it is highly probable, are larger, and others leſs: For a Ray of Light being received on a refracting Surface in a dark Place, is not wholly refracted, but ſplit, as it were, and diffuſed into ſeveral little Rays, ſome of which are refracted to the extreme Points, and others to the intermediate Points; *i. e.* thoſe Particles of the Light which are moſt minute, are diverted the moſt eaſily and moſt conſiderably of all others, by the Action of the refracting Surface, out of their rectilineal Courſe; and the reſt, as each exceeds another in Magnitude, ſo it is turned out of its right Line with more Difficulty, and leſs conſiderably.

Now each Ray of Light, as it differs from another in its Degree of Refrangibility, ſo likewiſe it differs from it in *Colour*: This is warranted by numerous Experiments.

Thoſe Particles which are moſt refracted, are found to conſtitute a Ray of a *Violet Colour*; *i. e.* in all Probability, the moſt minute Particles of Light, thus ſeparately impell'd, excite the ſhorteſt Vibration in the *Retina*, which are thence propagated by the ſolid Fibres of the Optick Nerves into the Brain, there to excite the Senſation of *Violet Colour*, as being the moſt duſky and languid of all *Colours*.

Again: Thoſe Particles which are the leaſt refracted, conſtitute a *Radiolus*, or little Ray, of a *Red Colour*, i. e. The largeſt Particles of Light excite the longeſt Vibrations in the *Retina*, ſo as to excite the Senſation of *Red Colour*, the brighteſt and moſt vivid of all *Colours*.

Authors diſtinguiſh three general Kinds of *Red*; one bordering on the *Blue*, as *Columbine*, or *Dove Colour*, *Purple* and *Crimſon*, &c. another bordering on *Yellow*, as *Flame Colour*, and *Orange*.

Between theſe Extremes is a Medium, which partakes neither of the one nor the other, and this is what we properly call *Red*.

Acids turn *Black*, *Violet* and *Blue* into *Red*; and *Red* into *Yellow*; and *Yellow* into a very *pale Yellow*.

Alcali's change *Red* into *Violet*, or *Purple* and *Yellow* into *Feuillemorte*, or *Dead Leaf Colour*.

Terreſtrial and Sulphureous Matters become *Red* by extreme Heat; and ſome at length *Black*, as we ſee in *Brick*, *Red Bole*, *Red Chalk*, *Slate*, *Pumice*, &c. which when vitrified by a Burning-glaſs, become *Black*.

Lobſters become *Red* by a moderate Fire; and by a violent one *Black*.

Mercury and *Sulphur* mixed and heated over a moderate Fire, make a beautiful *Red*, called *Artificial-cinnabar*.

An acid Spirit, as *Lemon-juice*, being poured on a *Blue* Solution of *Turnſole*, turns it into a beautiful *Red*; *Alkali* reſtores it to an original *Blue*; and filtrating the reddeſt Wine takes from it its *Red Colour*.

Monſ. *de la Hire* has obſerved, that a very luminous Body, ſeen thro' a *Black* one, always appears *Red*; as the Sun appears, when ſhining thro' a *Black* Cloud. He adds, That many People who ſee all the other Colours perfectly well, yet have no Idea of *Red*, and only ſee it perfectly *Black*. But to proceed:

The other Particles being in like Manner ſeparated, according to their reſpective Magnitudes, into little Rays, excite the intermediate Vibrations, and by this Means occaſion the Senſations of the intermediate *Colours*; much in the ſame Manner as the ſeveral Vibrations of the Air, according to their reſpective Magnitudes, excite the Senſations of different Sounds.

We may add to this, That not only the more diſtinct and notable *Colours* of *Red*, *Yellow*, *Blue*, &c. do thus take their Riſe from the different Magnitude and Refrangibility of the Rays; but alſo the intermediate Degrees or Teints of the ſame *Colour*; as *Yellow* up to *Green*, of *Red* down to *Yellow*, &c.

Farther: The *Colours* of theſe little Rays, not being any adventitious Modification thereof, but connate, primitive and neceſſary Properties, as conſiſting, in all Probability, in the Magnitudes of their Parts, muſt be perpetual and immutable, *i. e.* cannot be changed by any future Refraction or Reflection, or any Modification whatſoever.

This is confirmed by abundance of Experiments; all Endeavours having been uſed, after ſeparating a *colour'd* Ray from thoſe of other Kinds, to change it into ſome other *Colour* by repeated Refractions; but to no Effect.

Indeed, it is poſſible to effect apparent Tranſmutations of *Colours*, *viz.* where there is an Aſſemblage or Mixture of Rays of different Kinds; the component *Colours* never appearing in their natural Hue in ſuch Mixtures, but always allay'd and temper'd with each other: Whence a middling Kind of *Colour* does reſult; which may be ſeparated into the component ones by Refraction; and thoſe, after Separation, being remix'd, return to their former *Colour*.

Hence the Tranſmutations of *Colours*, by mixing thoſe of different Kinds, are not real, but mere Appearances or Deceptions of the Sight; for the Rays being again ſevered, exhibit the ſame *Colours* as they did at firſt: Thus *Blue* and *Yellow* Powders, being mix'd, appear *Green* to the naked Eye; yet without having paſſed any Alteration, when view'd thro' a Microſcope, the *Blue* and *Yellow* Particles will appear diſtinct.

Hence two Kinds of *Colours* do ariſe; the one *Original* and *Simple*, produced by homogeneous Light, or by Rays that have the ſame Degree of Refrangibility, and the ſame Magnitude of their Parts; ſuch are *Red*, *Yellow*, *Green*, *Blue*, a *Violet-purple*, *Orange*, and *Indigo*, with all their intermediate Teints and Degradations.

The other Kind of *Colours* is *Secondary* or heterogeneous compounded of the primary ones, or of a Mixture of Rays differently refrangible, *&c.*

There may alſo be *Secondary* Colours produced by Compoſition, like the primary ones, or thoſe conſiſting of homogeneal Light, as to the Species or Appearance of the *Colour*, but not as to the Permanency and Immutability of it.

Thus *Yellow* and *Blue* mix'd, make *Green*; *Red* and *Yellow* being mix'd, make *Orange*; *Orange* and *yellowiſh Green* mix'd, make *Yellow*.

And in the general, any two *Colours* being mix'd, which in the Series of thoſe generated by the Priſm are not too far apart, that *Colour* will reſult from this Mixture, which is found in the Mid-way between them in the ſaid Series: But thoſe will not do ſo that are ſituated at too great a Diſtance.

Indeed, the more any *Colour* is compounded, the leſs perfect and vivid it is; they may be diluted and weakened, till they ceaſe, by too much Compoſition. Alſo *Colours*, not like to any of thoſe of homogeneal Light, may be produced by Compoſition.

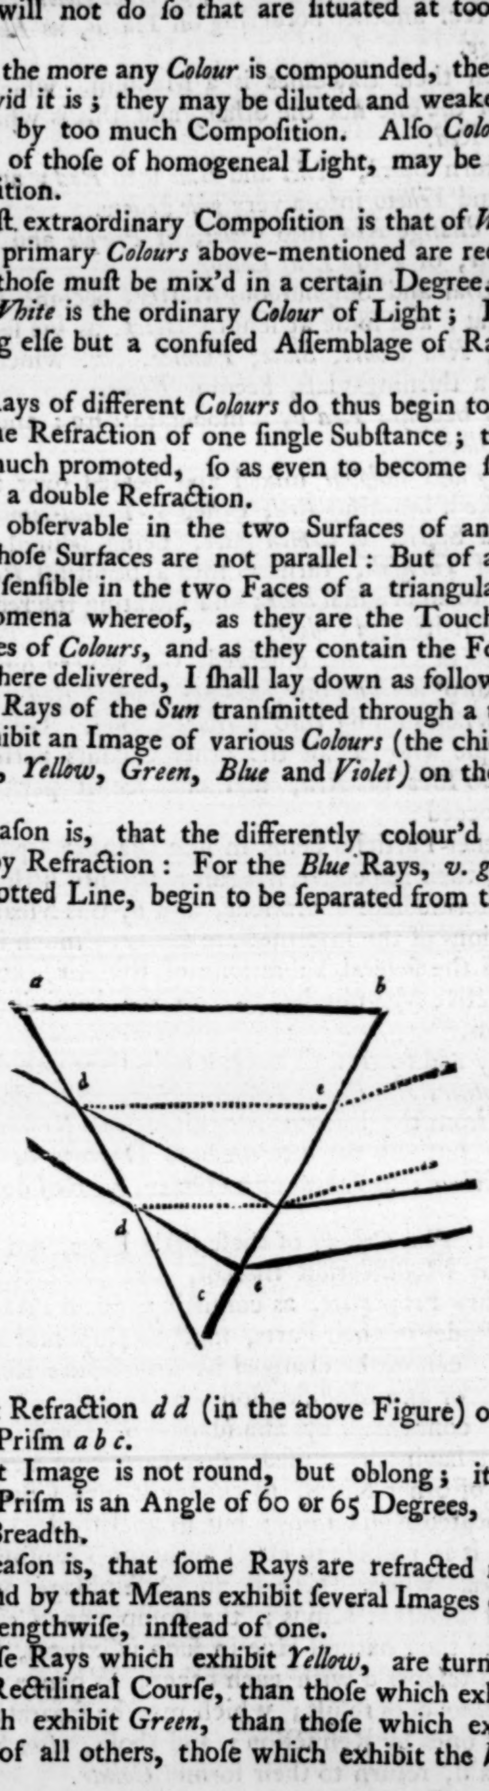
The moſt extraordinary Compoſition is that of *Whiteneſs*: For all the primary *Colours* above-mentioned are required to this; and thoſe muſt be mix'd in a certain Degree. Hence it is that *White* is the ordinary *Colour* of Light; Light being nothing elſe but a confuſed Aſſemblage of Rays of all *Colours*.

If the Rays of different *Colours* do thus begin to be ſeparated by one Refraction of one ſingle Subſtance; that Separation is much promoted, ſo as even to become ſenſible to the Eye by a double Refraction.

This is obſervable in the two Surfaces of any Glaſs; provided thoſe Surfaces are not parallel: But of all others, it is moſt ſenſible in the two Faces of a triangular Priſm; the Phænomena whereof, as they are the Touch-ſtone of all Theories of *Colours*, and as they contain the Foundation of what is here delivered, I ſhall lay down as follows:

1. The Rays of the *Sun* tranſmitted through a triangular Priſm, exhibit an Image of various *Colours* (the chief whereof are *Red*, *Yellow*, *Green*, *Blue* and *Violet*) on the oppoſite Wall.

The Reaſon is, that the differently colour'd Rays are ſeparated by Refraction: For the *Blue* Rays, *v. g.* marked with the dotted Line, begin to be ſeparated from the reſt by the firſt Refraction *d d* (in the above Figure) of the Side *c a* of the Priſm *a b c*.



2. That Image is not round, but oblong; its Length, when the Priſm is an Angle of 60 or 65 Degrees, being five times its Breadth.

The Reaſon is, that ſome Rays are refracted more than others; and by that Means exhibit ſeveral Images of the *Sun* extended lengthwiſe, inſtead of one.

3. Theſe Rays which exhibit *Yellow*, are turned farther from the Rectilineal Courſe, than thoſe which exhibit *Red*; thoſe which exhibit *Green*, than thoſe which exhibit *Yellow*; but of all others, thoſe which exhibit the *Violet*, the moſt.

Accordingly, if the Priſm through which the Light is tranſmitted be turned about its Axis, ſo as the *Red*, *Yellow*, *Green*, &c. Rays be projected in order through a narrow Aperture, into another Priſm placed at the Diſtance of about twelve Feet; the *Yellow*, *Green*, &c. Rays, though falling through the ſame Aperture in the ſame Manner, and on the ſame Point of the ſecond Priſm, will not be refracted to the ſame Place as the *Red*, but to a Point at ſome Diſtance from it, on that Side to which the Rotation was made.

This is what Sir *Iſaac Newton* calls *Experimentum Crucis*, being that which led him out of the Difficulties into which the firſt Phænomenon, *&c.* had brought him, and plainly ſhew'd a different Degree of Refrangibility, and a different *Colour* correſponding thereto in the Rays of Light; and that *Yellow* Rays, *v. g.* are more refracted than *Red* ones, and *Blue* and *Violet* moſt of all.

4. The *Colours* of colour'd Rays, well ſeparated by the Priſm, are not at all changed or deſtroy'd by paſſing an illuminated Medium, nor by their mutual Decuſſation, their bordering on a deep Shadow, nor being reflected from any natural Body, or reflected through any one, in a Place how obſcure ſoever.

The Reaſon is, that *Colours* are not Modifications ariſing from Refraction or Reflection, but immutable Properties, and ſuch as belong to the Nature of the Rays.

5. An Aſſemblage of all Kinds of colour'd Rays, collected either by ſeveral Priſms, by a Convex Lens, or a Concave Mirrour, or in any other Manner, form what we call *Whiteneſs*; yet each of theſe, after Decuſſation, becoming ſeparated, again exhibits its proper Colour: For as the Ray was *white* before its Parts were ſeparated, ſo the Parts being mix'd, it becomes *white* again; and coloured Rays, when they meet together, don't deſtroy one another, but are only interſperſed.

Hence a *red*, *green*, *yellow*, *blue*, and *violet* Colour, being mix'd in a certain Proportion, appear *whitiſh*; *i. e.* are of ſuch a Colour as ariſes from *White* and *Black* mix'd together, and would be plainly *white*, if ſome Rays were not abſorb'd and loſt.

In like manner, if a Paper cut into a Circle be ſtain'd with each of thoſe *Colours* ſeparately, and in a certain Proportion, then ſwiftly turned round its Centre, ſo as the Species of *Colours* be mixed together in the Eye by the Briskneſs of the Motion, the ſeveral *Colours* will diſappear, and the whole Paper appear of one continual Colour, which will be a Mean betwixt *White* and *Black*.

6. If the Rays of the Sun fall very obliquely on the inner Surface of a Priſm, thoſe that are reflected will be *Violet*, thoſe tranſmitted *Red*.

For the Rays were coloured before any Separation; and by how much the more they are refrangible, by ſo much they are the more eaſily reflected, and by that means are ſeparated.

7. If two hollow Priſms, the one filled with a *blue* Fluid, and the other with a *red* one, be joined together, they will be opaque, tho' each apart be tranſparent.

For the one tranſmitting none but *blue* Rays, and the other none but *red* ones; the two together will tranſmit none at all.

8. All natural Bodies, eſpecially *white* ones, view'd through a Priſm held to the Eye, appear fimbriated or bordered on one Side with *Red* and *Yellow*, and on the other Side with *Blue* and *Violet*.

For thoſe *Fimbriæ* are the Extremes of intire Images, which the Rays of any Kind, as they are more or leſs refracted, would exhibit nearer, or at a greater Diſtance from the real Place of the Object.

9. If two Priſms be ſo placed, as that the *Red* of the one, and the *Purple* of the other meet together, in a Paper fit for the Purpoſe, incompaſs'd with Darkneſs, the Image will appear pale; and if viewed through a third Priſm, held to the Eye at a proper Diſtance, it will appear double, the one *Red*, the other *Purple*.

In like manner, if two Powders, the one perfectly *Red*, the other *Blue*, be mixed, any little Body covered pretty deeply with this Mixture, and viewed through a Priſm held to the Eye, will exhibit a double Image, the one *Red*, and the other *Blue*; in regard that the *Red* and *Purple*, or *Blue* Rays are ſeparated by their unequal Refraction.

10. If the Rays tranſmitted thro' a Convex Lens, be received on a Paper, before they meet in a Focus, the Confines or Boundary of Light and Shadow, will appear tinged with a *red* Colour; but if they be received beyond the Focus, with a *blue* one.

Becauſe in the firſt Caſe, the *red* Rays being ſomething more refracted, are the higher; but in the ſecond, after Decuſſation in the Focus, the *blue* ones.

Laſtly, If the Rays about to paſs through either Side of the *Pupilla*, be not intercepted by the Interpoſition of any opaque Body near the Eye, the Extremes of Bodies, plac'd as if view'd through a Priſm, will appear ting'd with *Colours*, tho' thoſe are not very vivid.

For then the Rays tranſmitted through the reſt of the Pupil will be ſeparated by Refraction into *Colours*, without being diluted with the Admixture of the intercepted Rays, which would be refracted in a different Manner.

And hence it is, that a Body viewed thro' a Paper pierced with two Holes, appears double, and alſo tinged with *Colours*.

Of the Colours *of thin Plates.*] As Rays of different *Colours* are ſeparated by the Refraction of Priſms, and other thick Bodies, ſo are they ſeparated, tho' in a different Manner, in the thin *Lamellæ* or Plates of any pellucid Matter; *v. g.* the Bubbles raiſed in Water thickned by Soap, *&c.*

For all *Lamellæ* under a determined Thickneſs, in Arithmetical Proportion, begin to reflect firſt *Blue* Rays; then in order *Green*, *Yellow* and *Red*, all pure; then again *Blue*, *Green*, *Yellow*, and *Red*, all pure; then again, *Blue*, *Green*, *Yellow*, and *Red*, more and more mixed and diluted; till at length arriving at a certain Thickneſs, they reflect Rays of all Colours perfectly intermixed, *viz. White*.

But in whatſoever Part a ſlender *Lamella* reflects any one Colour, *v. g. Blue*, in that Part it always tranſmits the oppoſite Colour, *v. g. Red* or *Yellow*.

It is found by Experiment, that the Difference of Colour of a Plate, does not depend on the Medium that encompaſſes it; but the Degree of Vividneſs does: *cæteris paribus*, the Colour will be more vivid, if the denſer Medium be incompaſs'd with the rarer: A Plate, *cæteris paribus*, reflects more Light, as it is thinner, as far as a certain Degree of Thinneſs, beyond which it reflects no Light at all.

In Plates whoſe Thickneſs increaſe in an Arithmetical Proportion of the natural Numbers, 1, 2, 3, 4, 5, *&c.* if the firſt or thinneſt reflect any homogeneal Ray, the ſecond will tranſmit it; the third again will reflect it; and thus is the ſame Ray alternately reflected and tranſmitted; *i. e.* the Plates correſponding to the odd Number, 1, 3, 5, 7, *&c.* will reflect the ſame Rays that thoſe correſponding to the even ones 2, 4, 6, 8, *&c.* tranſmit.

Hence an homogeneal *Colour* in a Plate is ſaid to be of the *firſt Order*, if the Plate reflect all the Rays of that Colour: In a Plate whoſe Thinneſs is triple the firſt, it is ſaid to be of the *ſecond Order*: In another, whoſe Thinneſs is five times that of the firſt, it is ſaid to be of the *third Order*, &c.

A *Colour* of the firſt Order is more vivid than any; and ſucceſſively the Vividneſs of the *Colour* increaſes as the Quantity of the Order increaſes: The more the Thickneſs of the Plate is increaſed, the more *Colours* it reflects, and thoſe of more different Orders: In ſome Plates the *Colour* will vary as the Poſition of the Eye varies; in others it is permanent.

Colours *of Natural Bodies.*] Bodies only appear of different *Colours*, as their ſurfaces are diſpoſed to reflect Rays of this or that *Colour* alone, or of this or that *Colour* more abundantly than the other: Hence Bodies appear of that *Colour* that ariſes from the Mixture of the reflected Rays.

All *Natural Bodies* conſiſt of very thin tranſparent *Lamellæ*; which, if they be ſo diſpoſed with regard to each other, as that there happen no Reflections or Refractions in their Interſtices, thoſe Bodies become pellucid or tranſparent; but if their Intervals be ſo large, and thoſe filled with ſuch Matter, or ſo empty (and with regard to the Denſity of the Parts themſelves) that there happens a Number of Reflections and Refractions within the Body, the Body in that Caſe becomes opaque.

The Rays which are not reflected from an opaque Body, penetrate into it, and there ſuffering innumerable Reflections and Refractions, at length unite themſelves to the Particles of the Bodies themſelves.

Hence it is that an opaque Body grows hot the ſooner, as it reflects Light leſs copiouſly: hence we ſee, that a white Body, which reflects almoſt all the Rays that ſtrike upon it, heats much more ſlowly than a black one, which reflects ſcarce any.

In order to determine the Conſtitution of the Surface of Bodies wherein their *Colour* depends, it muſt be obſerved, that the ſmalleſt Corpuſcles or Particles whereof Surfaces are made up, are moſt thin and tranſparent, and ſeparated by a Medium of a different Denſity from the Particles themſelves.

In the Surface then of every coloured Body are innumerable ſmaller, thin Plates, anſwering to thoſe of Bubbles.

Hence it may be gathered, that the *Colour* of a Body depends upon the Denſity and Thickneſs of the Parts of the Body between the Pores of the Surface; that the *Colour* is more vivid and homogeneous, as the Parts are thinner; that, *cæteris paribus*, the ſaid Parts are the thickeſt when the Body is *Red*, and thinneſt when *Violet*.

That the Parts of Bodies are uſually much denſer than the Medium contained in their Interſtices; but that in the Tails of Peacocks, and ſome Silks, and generally in all Bodies whoſe *Colour* varies according to the Situation of the Eye, it is leſs; and that the *Colour* of the Body is leſs vivid to the Eye, as it has a denſer Medium within its Pores.

Now, of the ſeveral opaque Bodies, thoſe which conſiſt of the thinneſt *Lamellæ* are *Black*, thoſe conſiſting either of the thickeſt *Lamellæ*, or of *Lamellæ* very different from each other in Thickneſs, and on that account fitted to reflect all *Colours*, as the Froth of Water, *&c.* are *White*.

Thoſe again, which conſiſt of *Lamellæ*, moſt of which are of ſome intermediate Thickneſs, are *Blue*, *Green*, *Yellow*, or *Red*; inaſmuch as they reflect the Rays of that particular *Colour* much more copiouſly than that of any other *Colour*; moſt of which laſt they either abſorb and extinguiſh, by intercepting them, or elſe tranſmit.

Hence it is, that ſome Liquors, *v. g.* an Infuſion of *Lignum Nephriticum*, appear *Red* or *Yellow*, if viewed by reflected Light; and *Blue*, by tranſmitted Light; and Gold Leaves, *Yellow* in the former Circumſtances, but *Green* or *Blue* in the latter.

To this may be added, that ſome of the Powders uſed by Painters, have their *Colours* changed by being very finely ground; which muſt be occaſioned by the Comminution or Breaking of their ſmall Parts into others ſtill ſmaller; juſt as a *Lamella* has its Colour altered, by altering its Thickneſs.

In fine; Thoſe odd Phænomena ariſing from the Mixture of Liquors of different Colours, can no way be better accounted for than from the various Actions of the ſaline, *&c.* Corpuſcles of one Liquor, with the coloured Corpuſcles of another: If they unite, the Maſs will either ſwell or ſink; and thereby its Denſity will be altered. If they ferment, the Size of the Particles may be diminiſhed, and thereby coloured Liquors may become tranſparent: If they coagulate, an opaque Liquor may be produced of two tranſparent ones.

Hence it is eaſy to ſee, why a coloured Liquor in a Glaſs of a conical Figure, placed between the Eye and the Light, appears of a different Colour in different Parts of the Veſſel, there being more and more Rays intercepted, as they paſs thro' a longer or ſhorter Section of the Veſſel, till at the Baſe they are all intercepted, and none ſeen but thoſe reflected.

From the various *Colours* of natural Bodies, Sir *Iſaac Newton* obſerves, that the Bigneſs of their component Parts may be eſtimated, for that the Parts of Bodies do properly exhibit the ſame *Colour* with a *Lamella* of equal Thickneſs, provided the Denſity in both be the ſame.

Why the *Colours* of the Rainbow appear in falling Drops of Rain, is alſo from hence evident: For thoſe Drops which refract the Rays diſpoſed to appear Purple, in greateſt Quantity to the Spectator's Eye, refract the Rays of other Sorts ſo much leſs, as to make them paſs beſide it; and ſuch are the Drops of the Inſide of the *primary* Bow, and on the outſide of the *ſecondary* or exterior one: So theſe Drops which refract in greateſt Plenty the Rays apt to appear red to the Spectator's Eye, refract thoſe of other Sorts ſo much more as to make them paſs beſide it; and ſuch are the Drops on the exterior Part of the *primary*, and interior Part of the *ſecondary* Bow. See *Rainbow*.

It is very obſervable, that *White* is much brighter, as it is produced by a great Quantity of Rays; and the leſs Rays *Black* has, by ſo much the obſcurer it is.

Red is the medium Colour between theſe two Extremes; becauſe it contains as much Force of the one as the other: But *Yellow* contains more of the *White*, and *Blue* more of the *Black*.

Green is a Compound of *Yellow* and *Blue*; for if a Piece of *blue* Glaſs be laid upon a Piece of *yellow* Glaſs, and ſo placed between the Eye and the Object, whatſoever it is that is ſeen through them, will appear *green*.

But other *Colours* are not ſo inclinable to unite as *Blue* and *Yellow*; and for this a good Reaſon may be given, becauſe the Parts of all other ſuch like Mixtures are different in Proportion; and while there is any one Colour predominant, there can be no Union.

Father *Niceron* ſays, That *Red* is produced by an equal Interruption and Continuation of Rays; as if we ſuppoſed three continued Rays, and three Points of the Object which were dark: And this Suppoſition might give us to believe, that all *Colours* were compoſed of *White* and *Black*, that is to ſay, of certain Proportions of *Light* and *Darkneſs*: and nothing that is *Yellow* is equally diſtant from *White* and *Red*, as *Blue* is from *Red* and *Black*. But the following Table may better explain the Difference of theſe.

White has 100 Rays of *Light*.

Red is compoſed of equal Parts of *White* and *Black*; or of 50 Rays and 50 Points.

Black 100 Angles or Points of Darkneſs.

Yellow has 75 Rays, and 25 Points

Blue has 75 Points, and 25 Rays.

Green the Medium of *Blue* and *Yellow*.

Sanctorius will have all *Colours* to proceed from *Shade* and *Temperancy*; and produces an Experiment to prove that *White* and *Black* are each of them compoſed of tranſparent Globes; and that thoſe which give us the *White* are void and empty; and thoſe which produce the *Black*, he thinks, are full of Matter.

The *White* containing only Air, gives no Shade; but the *Black* gives Shade; for Air, and ſuch like ſubtil Bodies, make no Refraction.

Now, if we ſuppoſe all bright *Colours* to be compoſed of ſpherical Particles, then we may reaſonably imagine, that the brighteſt Sorts of them do conſiſt of ſmaller Globes than thoſe do that are more faint; becauſe, as *Sanctorius* ſays, we know that in all tranſparent Bodies in this Form, every ſingle Globe will ſend at leaſt one ſingle Ray to the Eye; and by ſo many the more there are of thoſe Rays, by ſo much the more ſuch *Colours* come nearer to *Light* itſelf, which as theſe Parts are more ſubtil and refined, is the more dazzling.

And in like manner the darker *Colours*, by how much the more they are compoſed either of more triangular Parts, or as the Parts that compoſe them tend towards the laſt conceivable Point of Magnitude, by ſo much they become more ſenſibly obſcure.

It may be farther obſerved, that *Heat* and *Cold* do neceſſarily reſult from *Light* and *Darkneſs*; the more moderate Points of which are *Yellow* and *Blue*, which together produce *Green*; and that ſeems to be the moſt prevailing *Colour* of the Earth.

It is alſo remarkable, that in the growing of Plants, the ſame Plants do, from time to time, alter and change their *Colours*, as the Veſſels which are in thoſe Shoots grow larger: The Leaves are of a faint *Yellow* when they are in their ſmaller State; but they become of a bright *Green*, or ſometimes *Red*, when they are in their middle State; but when their Veſſels are enlarged to their full Growth, they become of a dark *Green*, and then change to a *Feuillemort* Colour towards *Autumn*, from the ripening of their Juices; from thence to Putrefaction, which reſolves itſelf again into Earth, its firſt Principle.

VASCULIFEROUS PLANTS, are ſuch whoſe Seeds are contained in Veſſels which are ſometimes divided into Cells; and theſe have always a monopetalous Flower, either uniform or difform.

VASE, is ſometimes us'd for *Calyx*.

VASES: A *Vaſe* is a Sort of a Flower-Pot ſet in a Garden.

VEGETABLE, a Term applyed to all Plants, conſidered as capable of Growth, *i. e.* to all natural Bodies which have Parts organically formed for Generation and Accretion, but not for Senſation.

M. *Boerhaave* defines a *Vegetable* to be a Body generated of the Earth, to which it adheres, and is connected by Parts called Roots, through which it receives the Matter of its Nouriſhment and Increaſe, and conſiſts of Juices and Veſſels, ſenſibly diſtinct from each other: Or a *Vegetable* is an organical Body compoſed of Veſſels and Juices, every where diſtinguiſhable from each other, to which Roots grow, or Parts, by which it adheres to ſome other Body, from which it derives the Matter of its Life and Growth.

This Definition of a *Vegetable* is very *ſcientific*, and furniſhes us with a juſt and adequate Idea of it; for by its conſiſting of Veſſels and Juices, it is diſtinguiſhed from a *Foſſil*; and by its adhering to another Body, and deriving its Nouriſhment therefrom, it is diſtinguiſhed from an *Animal*.

He defines a *Vegetable* an *Organical Body*, becauſe it conſiſts of different Parts, which jointly concur to the Exerciſe of the ſame Function.

The Definition of its adhering by ſome of its Parts to another Body, is very proper; for we know of no Plant that is ſo abſolutely vague and fluctuating, but has ſtill a Body it adheres to; tho' that Body may be various, *e. g.* Earth, as in our common Plants; Stone, as in Rock Plants; Water, as in Sea Plants; Air, as in ſome Mucilages.

As to thoſe few Plants that appear to float with the Water, their Manner of Growth is ſomewhat anomalous: Monſieur *Tournefort* has ſhewn, That all Plants do not ariſe ſtrictly from Seeds; but that ſome, inſtead of Semen, depoſite or let fall a little Drop of Juice, which ſinking in the Water, by its Gravity reaches the Bottom, or ſome Rock, *&c.* in its Way, to which it ſticks, ſtrikes Root, and ſhoots into Branches: Such is the Origin of *Coral*.

To which may be added, That a Root of a Plant may have any Situation at Pleaſure with reſpect to the Body thereof; nor needs it be either loweſt or higheſt, *&c.* Accordingly, in *Coral*, *Moſſes*, *Fungus's*, &c. the Root is frequently uppermoſt, and its Growth downwards.

VEGETABLES are natural Bodies, having Parts organically formed, but without Senſation.

VEGETABLE STATICKS, ſignifies the Weight, or Gravity, and the Motion of the Juices in *vegetable* Bodies.

It will not, I hope, be thought improper to ſet down that curious Account of a Book (intitled *Vegetable Staticks*, being an Eſſay towards a Natural Hiſtory of *Vegetation*, by *Stephen Hales*, D. D. and F. R. S.) which was drawn up by Dr. *Deſaguliers*, and publiſhed in the *Philoſophical Tranſactions*, ſince it will not only give the Reader an Idea of the many curious Experiments which are contained in that Book; but alſo give him a much clearer Notion of the Buſineſs of *Vegetation* than can be found in any Books yet extant.

The incomparable Sir *Iſaac Newton* has not only ſhorten'd the Geometrician's Work, by his wonderful Diſcoveries in abſtract Mathematicks, but has alſo taught us, by his own Practice, how to make and judge of Experiments and Obſervations with the utmoſt Accuracy: And as he avoided making *Hypotheſes*, he was ſo cautious as to deliver only by way of Queries ſeveral Truths which he was convinced of, becauſe he wanted a ſufficient Number of Experiments to make them as evident as thoſe others, whereby he has ſo far improved and advanced natural Knowledge.

The Reverend Dr. *Hales* has followed his Steps, aſſerting nothing but what is evidently deduced from thoſe Experiments, which he has carefully made, and faithfully related; giving an exact Account of the Weights, Meaſures, Powers and Velocities, and other Circumſtances of the Things he obſerved; with ſo plain a Deſcription of his *Apparatus*, and manner of making every Experiment and Obſervation, that as his Conſequences are juſtly and eaſily drawn, ſo his Premiſes or Facts may be judged of by any body that will be at Pains to make the Experiments; which are moſt of them very eaſy and ſimple.

His Account of every thing is written in ſuch an intelligible Manner, that the inquiſitive Reader is capable of underſtanding it without being puzzled with perplexed Calculations and complex Experiments, which Authors have ſometimes contrived, in order to be admired for thoſe Things which they themſelves found out, either by mere Chance, or with very little Labour: He has illuſtrated, and put paſt all Doubt, ſeveral Truths mentioned in Sir *Iſaac Newton*'s Queries; which tho' believed by ſome of our eminent Philoſophers, were called in Queſtion by others of an inferior Claſs, who were not acquainted with thoſe Facts and Experiments upon which Sir *Iſaac Newton* had built thoſe Queries.

An Abſtract of each Head is as follows.

I. *Experiments, ſhewing the Quantity of Moiſture imbib'd and perſpir'd by Plants and Trees.*

The Author having covered, with Mill'd Lead, a Garden-Pot, in which a Sun-flower was growing, ſo as to leave only one Paſſage for Air to communicate, and another to pour in Water to water the Plant, made ſeveral curious Experiments upon it.

1. That the Plants which weighed about 3 Pounds, perſpired about 30 Ounces in a 12 Hours Day, in the Month of *July* 1724. but in a warm Night it perſpired only 3 Ounces, and nothing in a cold Night; nay ſometimes it gained weight by imbibing Dew.

2. That as the Area of the Surface of the Leaves was equal to 5616 ſquare Inches; and the Area of the Roots only to 2286 ſquare Inches, the Water or Moiſture imbib'd by the Roots to ſupply the Perſpiration at the Leaves, muſt move

faſter in the Roots than through the Leaves, in the Proportion of 5 to 2. But in the Stem, whoſe tranſverſe Section was one ſquare Inch, faſter than in the Leaves, in the Proportion of 5616 to one.

3. That by comparing his Experiments made on this and other *Sun-flowers* and *Plants* with Dr. *Keil*'s Experiments mention'd in the *Medicina Statica Britannica*, it is evident, that a Man (Surface for Surface) perſpires more than a Plant, in the Proportion of 3 ½ to 1. That the Quantity of the Food of a Man is to the Food of a Plant nearly as 7 to 2; but Bulk for Bulk, the Plant imbibes into its Veſſels 17 times more Fluid than the Quantity of the Chyle which enters into a Man's Veſſels; and that becauſe, as the Sap to Plants is leſs nutritive than Chyle to Man, it muſt be more in Quantity: To ſuck in the more Sap, a Plant has a very great Surface, and thereby (Perſpiration promoting its imbibing of the Sap) perſpires 17 times more than a Man, in Proportion to their reſpective Weights.

4. That a Man or Plant may perſpire different Quantities, and yet continue in an healthy State.

A Man may perſpire in 24 Hours from 1 Pound and an half to three Pounds; and a Plant, which at one time perſpired but 16 Ounces, may, without being leſs healthy, perſpire 28 Ounces in the ſame time.

Dr. *Hales* obſerv'd, That, in order to ſupply the Evaporation in the Leaves of a Vine, the Sap roſe 150 Inches in 12 Hours, ſuppoſe the Sap to riſe as denſe as Water; but if it riſes in a Steam, which muſt at leaſt be ten times rarer than Water, then the Velocity of the Sap will be ten times greater, and conſequently riſe at the rate of 125 Inches in an Hour.

N. B. *That the Heat of the Sun ſhould rareſy the Moiſture of the Earth to that Degree, or a great deal more, to drive it into the Roots of Plants, is very probable from ſome Obſervations made by Mr.* H. Beighton *and Dr.* Deſaguliers *upon the Engine to raiſe Water by Fire; whereby it appears that the Steam or Vapour of boiling Water is rarer than the Water from which it was produced above 13,000 times, when its Elaſticity is equal to that of common Air.*

This curious Experimenter, by his Obſervations on twelve *Ever-greens*, found, that they perſpire much leſs than other Plants, and compares them to the exanguous Tribe of Animals; which as they perſpire little, ſo they live the whole *Winter* without Food. He likewiſe obſerved, what Part of an Inch in Thickneſs is perſpired by a Man, and by ſeveral Plants: By a Man in 24 Hours $\frac{1}{30}$ Part of an Inch; and by the following Plants, *viz.* the *Vine*, the *Sun-flower*, the *Cabbage*, the *Apple-tree*, the *Lemon-tree*, $\frac{1}{191}$ $\frac{1}{165}$ $\frac{1}{104}$ $\frac{1}{241}$ Part of an Inch in 12 Hours.

That when the perſpiring Surface is diminiſhed by taking away the Leaves, the Power of imbibing is likewiſe diminiſhed; for the ſame which, with the Leaves on, imbibed 30 Ounces in 12 Hours, without the Leaves, imbibed only 1 Ounce.

That Fruit will imbibe through the Stem, in Proportion to its Surface, he tried in an *Apple*, which imbibed as much as two Leaves equal to it in Subſtance.

That as the Leaves draw Nouriſhment to the Bloſſoms and Fruit, ſo they grow large firſt in thoſe Places where the Bloſſoms are.

That *Hops* in the Middle of an Hop-ground thrive beſt, becauſe they imbibe and perſpire leaſt.

That by 9000 *Hop-Vines* growing on one Acre of Ground, 220 Gallons of Water are imbibed in a 12 Hours Day; which Quantity of Water is equal to a Depth of $\frac{1}{101}$ Part of an Inch ſpread on the ſame Surface.

That Fire-blaſts (as the Gardeners call them) may be occaſioned by ſolar Rays reflected from, or condenſed by Clouds, or even collected by Means of the denſe Steams, which ariſe moſt plentifully in the Middle of the Hop-ground.

That the perſpiring Matter of Trees is not protruded by the Power of the Veſſels, but exhaled by Heat; which he proves by ſeveral curious Experiments.

He made Trees imbibe Spirit of Wine, and other Liquors impregnated with Aromaticks, which gave a Smell and Taſte to the Stalk, Leaves and Wood, but could not penetrate to the Fruit, by reaſon of the Fineneſs of the Capillary Sap-veſſels near the Fruit, which aſſimilated to their own Subſtance the high-taſted and perfum'd Liquors. Spirits kill'd the Trees, as far as they were imbibed, but ſcented Waters did not.

He receiv'd in proper Veſſels the Matter perſpir'd from Trees, which is a taſteleſs Water, but corrupts and ſtinks ſooner than common Water.

He weigh'd three Cubick Feet of the ſame ſort of (Brick) Earth, taken from the Surface of the Earth downwards, in *July* 1724, the lighteſt of which was about twice the ſpecifick Gravity of Water: Then ſetting them to dry, found, by the Loſs of Weight, how much Water they contain'd; the greateſt Quantity exhaled from a Cubick Foot being 10 Pounds, and the leaſt 6 Pounds 11 Ounces, *Averdupois* Weight.

In order to find the Heat of the external Air in Green-houſes and Stoves; as alſo the Degrees of Heat at ſeveral Depths of the Earth, and in Hot-beds, he provided ſix Thermometers, the Stems of which were of different Lengths, but adjuſted in their mark'd Degrees; ſo that they began at their freezing Point, and ended at 90 Degrees, where the Heat was equal to warm Water, that may be borne by the Hand, without ſtirring it about, which is the middle Point between Freezing and the Heat of boiling.

By theſe Thermometers, he obſerved the Degrees of Heat, in ſeveral Caſes, to be as follows: *Of the Blood*=64. *Of the Human Body*=54. *Milk from the Cow, and Heat fit to hatch Eggs,*=55. *Urine*=58. *Temperate Air*=18. *Greateſt Heat of Sun-ſhine in the Year* 1724=74; *and in the Year* 1727 *at* 76. *The Common Heat of the Noon-Sun in* July=50. *Air in the Shade at the ſame time*=38. *The Heat in* May *or* June, *fitteſt for Plants*=*from* 17 *to* 30 *Degrees. Autumnal Heat*=*from* 10 *to* 20. *A Hot-bed too hot for Plants, and about the Heat of Blood in Fevers,*=75. *Due Heat of a Hot-bed*=56. *Heat under a Glaſs at the ſame time*=34; *and in the open Air*=17.

He obſerved the Air to be cooler than the Earth out of the Sun, but hotter in Sun-ſhine; and that as ſoon as the Sun is ſo far decreaſed, as no longer to give a briſk Agitation to (or turn into Steam) the Moiſture of the Earth, the Leaves of the Plants fall of.

II. *Experiments to find the Force with which Trees imbibe Moiſture.*

This Author contrived an *Aqueo-mercurial* Gage, in order to make a juſt Eſtimate of the Force with which the Moiſture is drawn up by Plants and Trees.

He took a Glaſs Tube of an Inch diameter, and about eight Inches long; into one End of which he cemented a ſmaller Tube of about one-fourth of an Inch diameter, and eighteen Inches long; into the other End he ſucceſſively cemented a Root, or Branch, or Stem of a Tree or Plant, whoſe imbibing Force he wanted to find out: which he did in the following Manner; *viz.*

He turned the ſmall end of the Gage upwards, and having poured Water into it, down upon the Wood cemented in, he ſtopped the Orifice with his Finger; then turning the little End downward again, he placed it into a Veſſel of *Mercury*, before he took off his Finger: Which when he had done, he made his Obſervations.

For as the Plant imbibed the Water, the *Mercury* roſe up in the ſmall Tube, following the Water, and ſhewing, by its Height, the Force of imbibing; and for every Inch that the *Mercury* roſe, Water would have riſen 13 ½ Inches, as it is ſo much lighter ſpecifically than *Mercury*.

With this Gage he made Experiments upon Roots and Branches in an erect, Branches in an inverted Situation; large ones as well as ſmall, even to Sprigs of Plants and Fruits, and found that all of them imbibed the Water, ſo as to raiſe the *Mercury* in the ſmall Tube, but to different Heights.

The *Mercury* was rais'd the quickeſt, and to the greateſt Height, *viz.* twelve Inches in ſeven Minutes by a *Nonpareil* Branch, two Feet high, with twenty Apples, and ſeveral lateral Branches, whoſe tranſverſe Section was five-eighths of an Inch diameter.

It is to be obſerved, that the *Mercury* roſe higheſt in a warm Sun: but the whole Force of imbibing was much greater than the *Mercury* ſhould ſhew; becauſe ſeveral Bubbles of Air came out of the Section of the Branch as the Water went up, which happened moſt in large Branches, which raiſed the *Mercury* but to a ſmall Height; but Branches ſtripp'd of their Leaves, hardly raiſed it all.

He alſo made *Peaſe* imbibe Water under the Preſſure of great Weights, and found that *Peaſe*, when ſwell'd, ſuſtain'd a Weight equal to 1600 Pounds, by their Force of imbibing and growing.

The Force of imbibing, he ſhews to be owing to the attractive Power of the Particles of which Plants are made up; all Kinds of Wood (even Cork) when their Particles are well ſoak'd, being heavier than Water.

N. B. *It is very difficult to ſoak Cork ſo thoroughly as to make it heavier than Water: but it was found to be true, in a Tube where a Cork had been ſeal'd up with Water for four Years, ſo as to be moveable in the ſaid Water.*

III. *Experiments ſhewing the Force of the Riſe of the Sap in the Vine in the bleeding Seaſon.*

The ſaid Author, by a very curious Contrivance of Glaſs Tubes, ſcrew'd and cemented at the Top of one another, and altogether fixed to the Stem of a Vine, obſerv'd, that in the bleeding Seaſon, *viz.* in *March* and *April*, the Sap will riſe into the Tubes, by the Force of the Roots and Stem, to very great Heights, even above the Top of the Vine, as it did up to the Top of a Tube twenty-five Feet high, in two Hours, and run out at the ſaid Tube, though ſeven Feet above the Top of the Vine: but the Force was ſuch, that the *Mercury*, in a Gage (in other Experiments) was puſh'd up 32 ^{1} Inches high, which was equivalent to above 43 Feet of Water.

This is a much greater Force than the Blood is impelled with in Animals: which laſt Force he try'd in the Crural Artery of an Horſe, of a Dog, and of a Deer; for having ty'd them down alive upon their Backs, and fix'd a Glaſs Tube to the Crural Artery opened, he found that in the Horſe the Blood aroſe above eight Feet, in the Dog about ſeven Feet, and in the Deer not quite ſix: And theſe Heights are five, ſeven, and eight times leſs than the Height to which the Sap is raiſed by the Vine.

The Sap riſes all Night, but moſt in the Morning of a warm Day; but in very hot Weather it ceaſes to riſe about ten in the Morning, and then begins to riſe again about three or four in the Afternoon; and, during the great Heat, Bubbles of Air drawn in by the Roots, come up the Tube from the Section of the Stem, the Sap in the Tube ſinking and riſing as the Weather is cloudy or clear, like the Liquor in a Thermometer.

That the Force was not only in the Root, but in the Stem and Branches, appear'd by ſeveral Experiments: One of which was, That a Vine at forty-four Feet four Inches in Diſtance from the Root, puſh'd up Sap with the Force of a Column of thirty Feet eleven Inches of Water.

He alſo ſhews, by a nice Experiment, that the Sap does not come indifferently through all the *Interſtices* of the Wood, but is confined to its proper Veſſels.

The Fibres of Capillary Tubes, out of the bleeding Seaſon, cannot protrude the Sap beyond their Orifices in the Section of the Stem: but aſſiſted by the Perſpiration of the Leaves, the Sap will riſe in that very Branch; which will imbibe Water, if it was cut off, and a Tube applied to it, with Water pour'd in; nay, it would alſo imbibe Water at the ſmall End.

IV. *Experiments ſhewing the ready lateral Motion of the Sap, and conſequently the lateral Communication of the Sap-veſſels; the free Paſſage of it from the ſmall Branches towards the Stem, as well as from the Stem to the Branches; with an Account of ſome Experiments relating to the Circulation and Non-circulation of the Sap.*

The Analogy there is, in many reſpects, between Plants and Animals, has given Occaſion to ſeveral ingenious Perſons to imagine, that the Sap muſt circulate in Plants, as the Blood does in Animals: and being fond of this new Hypotheſis, they have contented themſelves with a few Experiments that ſeem to confirm the Notion; and inſtead of making a ſufficient Number of Experiments and Obſervations, and, comparing them impartially, they have ſupply'd the reſt by Conjectures, and endeavour'd to ſupport their Hypotheſis by other new Suppoſitions.

It is upon this Account they have ſuppoſed particular Veſſels (like Arteries) to carry up the Sap from the Roots to the Extremities or Leaves; and others (like Veins) to bring down the Sap back again to the Roots, imagining the former to come down between the Bark and the Wood: But they did not conſider, that a Plant is very differently nouriſhed from an Animal, and therefore requires a very different Mechaniſm and Structure for its Growth and Support.

The reverend Dr. *Hales* has diſproved the above-mentioned Opinion, by ſeveral Experiments and Obſervations; the chief of which are theſe that follow:

1. Having cut a long Notch in a growing Branch which had Leaves on, he obſerved that the Notch was moiſt at the Bottom towards the Root, and not at the Top.

2. He made the ſame Experiment with another Branch ſet in Water, which imbibed the Liquor at a tranſverſe Section below the Notch, and found the Notch as before.

3. He obſerved, that in the *Spring* the Sap riſes plentifully between the Bark and the Wood, and that chiefly in Vines, and that if a Ringlet of Bark be taken off all round in bleeding Trees, the Bleeding abates moſt in the upper Part of the bare Place.

4. The Sap will move any Way by the Attraction of the ſame Capillary Tubes, and Perſpiration of the Leaves, ſhewn by the Branch of an *Apple-tree*, which drew up Moiſture plentifully at the ſmall End: Alſo by a Tree which throve, tho' its Root was taken out of the Ground, receiving its Nouriſhment only from two other Trees to which it was inarched, and from which it was ſuſpended; and likewiſe by a Bough, with two Branches cut off from a Tree; one Branch of which out of the Water, preſerved its Verdure, and received its Nouriſhment from the other Branch immers'd in Water, whilſt another Bough of the ſame Sort, without that Help, immediately withered.

By another Experiment, he proved chiefly, that there is a lateral Motion of the Sap through Veſſels, whereby the longitudinal Capillary Fibres communicate with one another, *viz.*

He cut four long Notches, one above another (but looking towards the ſeveral Cardinal Points) in a pretty large Branch, whoſe Section, ſome Inches below the ſaid Notches, was immers'd in Water; and found, that by the Attraction of the Fibres, and Perſpiration of the Leaves, the Moiſture roſe plentifully, notwithſtanding that the Continuity of the greateſt part (if not all) the longitudinal Fibres, was deſtroyed by thoſe deep Notches.

The lateral Motion may alſo be deduced from obſerving, that Branches will grow out of Roots, and thrive very well; and that *Elders*, *Sallows*, *Willows*, *Briers*, and *Vines* will grow, by putting either End of a Stem or Branch into the Ground.

He obſerves, that there is indeed an alternate receding and progreſſive Motion of the Sap, which recedes when cold Weather and Rain ſucceeds hot Sun-ſhine, the Trees then imbibing the Rains and Dews which fall upon the Leaves; but, upon the Return of the hot Weather, the Perſpiration is renewed, and the Sap riſes again.

This is ſufficient to account for *Jeſſamine* and the *Paſſion-tree* receiving a gilded Tincture below the gilded inoculated Bud; which has been given as an Inſtance of the Circulation of the Sap; but the *Ilex* grafted on the *Engliſh Oak*, as it keeps (whilſt the *Oak* ſheds) its Leaves in *Winter*, ſhews that the Sap does not circulate.

V. *Experiments whereby to prove, that a great Quantity of Air is inſpired by Plants.*

He makes it appear on this Head, that Plants imbibe a great deal of Air, not only that which comes up with the Sap from the Earth, (the Earth containing Air both in an elaſtick and in a fixed State) but alſo take it in thro' the old Eyes and Bark, eſpecially at Night, when the Plants are in an imbibing State.

The Experiments whereby he proves the ſaid Aſſertion, are chiefly theſe; *viz.*

1. An open, empty Glaſs Tube ſet upright, had an *Apple* Branch cemented in its upper end, the other end ſet in a Veſſel of Water; upon which the Air went up into the Branch out of the Tube, as appeared by the riſing of the Water into the Tube.

2. A Cylinder of Birch about ¾ of an Inch diameter, with the Bark on, cemented in the Middle to the Top of the Air-pump Receiver, ſo as to fill up the Hole at the Top of the ſaid Receiver upon the plate of the Air-pump; then, in working the Pump, Air came out at the Bottom of the ſaid Cylinder (bubbling up through the Water in the Veſſel) whether erect or inverted, cemented cloſe on the Top-ſection or not, and whether the old Eyes in the Sides were cemented up, or left bare, the Bark itſelf being pervious to the Air; but then it took in leſs Air than when the old Eyes and upper Section were open.

3. When Water (poured into a cylindrick Glaſs fixed over the Receiver) covered that Part of the Wood which was out of the Receiver, no Air came thro' the Bottom; and when the Water was taken away from covering the upper Part of the Wood, the Air did not come in through the Bottom, 'till the Top of the Cylinder of Wood had its Bark well dried.

4. He obſerves, with Dr. *Grew*, that the Mouths of the Air-veſſels are viſible in the Leaves of *Pines*, and in the Trunks of ſeveral Plants, with a Microſcope; and in ſome even without a Glaſs.

5. In making Experimens upon young Shoots, as their Veſſels are full of Sap, he did not find that the Air paſſed into or through them, (the Air in them, probably, being become fixed); but it came in freely at the Roots, applyed to the Air-pump in the ſame Manner as in the Piece of Birch.

VI. *A Specimen of an Attempt to analize the* Air, *by the Reverend Dr.* Stephen Hales, *by a great Variety of Chymico-ſtatical Experiments, which ſhew in how great a Proportion* Air *is wrought into the Compoſition of* animal, vegetable, *and* mineral *Subſtances; and withal, how readily it reſumes its former elaſtick State, when, in the Diſſolution of thoſe Subſtances it is diſengaged from them.*

The excellent Mr. *Boyle*, among his many Diſcoveries, found that Air was producible from *Vegetables*, by putting *Grapes*, *Plums*, *Gooſeberries*, *Cherries*, *Peaſe*, and ſeveral other Sorts of Grain, into exhauſted and unexhauſted Receivers, where they continued ſeveral Days, emitting great Quantities of Air. But Mr. *Boyle* did not ſhew the Way to know exactly, how much Air a certain Quantity of *vegetable* Subſtance will produce.

The incomparable Sir *Iſaac Newton*, (*Query* 31 of his *Opticks*) obſerves, “That true permanent Air ariſes by Fermentation or Heat, from thoſe Bodies which the Chymiſts call *fixed*, whoſe Particles adhere by a ſtrong Attraction, and are not therefore ſeparated and rarefied without Fermentation.

“Thoſe Particles receding from one another with the greateſt repulſive Force, and being moſt difficultly brought together, which, upon Contact, were moſt ſtrongly united. And (*Query* 80.) denſe Bodies, by Fermentation, rarefy into ſeveral Sorts of Air; and this Air, by Fermentation, and ſometimes without it, returns into denſe Bodies.”

The Reverend Dr. *Hales*, from the Conſideration of this and ſome of his own Experiments, concluded, that there muſt be Air not only in an elaſtick, but in a fixed State, in *Vegetables* and other Subſtances, and therefore that the Air-pump would not be ſufficient to get all the Air out of Bodies: For which Reaſon, he contrived Ways of getting the Air out of ſeveral Subſtances, by Fire (diſtilling them) and Fermentation, and made uſe of a very ingenious, but ſimple and certain Method, of meaſuring the Quantity of Air generated from (or abſorbed by) the ſeveral Kinds of Bodies, upon which he made Experiments.

The Deſcription of his Hydroſtatical Gages, and the Manner of his making his Experiments, not being to be given better and ſhorter than in his own Words, is as follows:

“In order to make an Eſtimate of the Quantity of Air, which aroſe from any Body by Diſtillation or Fuſion, I firſt put the Matter, which I intended to diſtil, into a ſmall Retort *r* (*Fig.* 4.) and then at *a* cemented faſt to it the Glaſs Veſſel *a b*, which was very capacious at *b*, with a Hole in the Bottom.

“I bound a Bladder over the Cement, which was made of Tobacco-pipe Clay and Bean Flower, well mixed with ſome Hair, tying, over all, four ſmall Sticks, which ſerv'd as Splinters to ſtrengthen the Joint: Sometimes inſtead of the Glaſs Veſſel *a b*, I made uſe of a large Bolt-head, which had a round Hole cut, with a red-hot Iron Ring at the Bottom of it, thro' which Hole was put one Leg of an inverted Syphon, which reached up as far as *z*. Matters being thus prepared, holding the Retort uppermoſt, I immerſed the Bolt-head into a large Veſſel of Water, to *a*, the Top of the Bolt-head: As the Water ruſhed in at the Bottom of the Bolt-head, the Air was driven out through the Syphon: when the Bolt-head was full of Water to *z*, then I cloſed the outward Orifice of the Syphon with the End of my Finger, and, at the ſame Time drew the other Leg of it out of the Bolt-head, by which Means the Water continued up to *z*, and could not ſubſide. Then I placed under the Bolt-head, while it was in the Water, the Veſſel *x x*: Which done, I lifted the Veſſel *x x*, with the Bolt-head in it, out of the Water, and tied a waxed Thread at *z*, to mark the Height of the Water, and then approach'd the Retort gradually to the Fire, taking care to ſkreen the whole Bolt-head from the Heat of the Fire.

“The Deſcent of the Water on the Bolt-head, ſhewed the Sums of the Expanſion of the Air in the Retort, and of the Matter which was diſtilling: The Expanſion of the Air alone, when the lower Part of the Retort was beginning to be red hot, was, at a Medium, nearly equal to the Capacity of the Retort, ſo that it then took up a double Space, and in a white and almoſt melting Heat, the Air took up a triple Space, or ſomething more; for which Reaſon, the leaſt Retorts are beſt for theſe Experiments. The Expanſion of the diſtilling Bodies was ſometimes very little, and ſometimes many times greater than that of the Air in the Retort, according to their different Natures.

“When the Matter was ſufficiently diſtilled, the Retort, *&c.* was gradually removed from the Fire, and, when cool enough, was carried into another Room, where there was no Fire. When all was thoroughly cold, either the following Day, or ſometimes three or four Days after, I marked the Surface of the Water *y*, where it then ſtood. If the Surface of the Water was below *z*, then the empty Space between *y* and *z*, ſhewed how much Air was generated, or raiſed from a fixed to an elaſtick State, by the Action of the Fire in Diſtillation: But if *y*, the Surface of the Water, was above *z*, the Space between *z* and *y*, which was filled with Water, ſhew'd the Quantity of Air which had been abſorbed in the Operation, *i. e.* was changed from a repelling elaſtick, to a fixed State, by the ſtrong Attraction of other Particles, which I therefore call *abſorbing*.

“When I would meaſure the Quantity of this new-generated Air, I ſeparated the Bolt-head from the Retort; and putting a Cork into the ſmall End of the Bolt-head, I inverted it, and poured in Water to *z*: Then, from another Veſſel (in which I had a known Quantity of Water by Weight) I pour'd in Water to *y*; ſo the Quantity of Water which was wanting, upon weighing this Veſſel again, was equal to the Bulk of the new-generated Air. I choſe to meaſure the Quantities of Air, and the Matter from whence it aroſe, by one common Meaſure of cubick Inches, eſtimated from the ſpecifick Gravities of the ſeveral Subſtances, that thereby the Proportion of one to the other might be the more readily ſeen.

“I made Uſe of the following Means to meaſure the great Quantities of Air, which were either raiſed and generated, or abſorbed by the Fermentation ariſing from the Mixture of Variety of ſolid and fluid Subſtances, whereby I could eaſily eſtimate the ſurpriſing Effects of Fermentation on the Air; *viz.* I put into the Bolt-head *b* (*Fig.* 5.) the Ingredients, and then run the long Neck of the Bolt-head into the deep cylindrical Glaſs *a y*: and inclined the inverted Glaſs *a y* and Bolt-head almoſt horizontally in a large Veſſel of Water, that the Water might run into the Glaſs *a y*: When it was almoſt up to *a*, the Top of the Bolt-head, I then immerſed the Bottom of the Bolt-head, and lower Part *y* of the cylindrical Glaſs under Water, raiſing at the ſame Time the End *a* uppermoſt. Then, before I took them out of the Water, I ſet the Bolt-head, and lower Part of the cylindrical Glaſs *a y*, into the Earthen Veſſel *x x*, full of Water; and having liſted all out of the great Veſſel of Water, I marked the Surface *z* of the Water in the Glaſs *a y*.

“If the Ingredients in the Bolt-head, upon fermenting, generated Air, then the Water would fall from *z* to *y*, and the empty Space *z y* was equal to the Bulk of the Quantity of Air generated: But if the Ingredients, upon Fermentation, did abſorb or fix the active Particles of Air, then the Surface of the Water would aſcend from *z* to *n*: and the Space *z n*, which was filled with Water, was equal to the Bulk of Air which was abſorbed by the Ingredients, or by the Fume ariſing from them. When the Quantities of Æther, either generated or abſorbed, were very great, then I made uſe of large chymical Receivers, inſtead of the Glaſs *a y*: But if theſe Quantities were very ſmall, then, inſtead of the Bolt-head, and deep cylindrical Glaſs *a y*, I uſed a ſmall cylindrical Glaſs, or a common Beer Glaſs inverted, and placed under it a Phial or Jelly Glaſs, taking Care that the Water did not come at the Ingredients in them; which was eaſily prevented by drawing the Water up under the inverted Glaſs to what Height I pleaſed, by Means of a Syphon.

“I meaſured the Bulk of the Spaces *z y*, or *z n*, by pouring in a known Quantity of Water, as in the foregoing Experiment, and making an Allowance for the Bulk of the Neck of the Bolt-head within the Space *z y*.”

By theſe Experiments that the ingenious Author made upon ſeveral Subſtances, it appeared, that ſome by Diſtillation, and ſome by Fermentation, would generate Air, others would abſorb it; and ſome again would abſorb Air at one time, and generate it at another; and oftentimes, that more Air was generated by Fermentation than by Fire. I have made a TABLE, the better to demonſtrate what the Effects were, which I ſhall inſert in the ſucceeding Page, that the Reader may have it before him at one View.

Dr. *Deſaguliers* adds, That as ſeveral Perſons may be willing to try a great many of Dr. *Hales*'s Experiments, he thought it proper to mention here, that the Experiments on Subſtances that generate Air, made with a Glaſs Retort, are difficult and tedious; but a Muſket Barrel, with the Touch-hole welded up, and then turned into a Semicircle, makes a very commodious Iron Retort, whoſe cloſe End being put into the Fire of a Smith's Forge, will be ſo heated, with a little blowing, as to get the Air out of any Subſtance in a very little time; having firſt twiſted on, upon the open End of the Barrel, one end of a leaden Syphon, (which will be very tight, with only a little Sheep's Leather between) whilſt the other End of the Syphon goes up a little Way into an inverted Chymical Receiver, filled with Water.

As the Air gets out of the Subſtances diſtill'd, it comes bubbling up through the Water, which it depreſſes by its Bulk.

N. B. *Antimony and Sulphur muſt not be made Uſe of in this Barrel, becauſe they will demetalize the Iron; nor Lead, becauſe it will ſweat out through the Iron.*

The ſaid **TABLE** *is as follows.*

Bodies which generated Air.	Bodies which abſorb'd Air.	Bodies which ſometimes generated and ſometimes abſorb'd Air.
Hog's Blood.	Salt of *Sal Armoniac.*	Gun-powder.
Tallow.	*Phoſphorus.*	Apples maſh'd.
Fallow Deer's Horn.	Acid Spirits.	Filings of Steel and *Aqua-fortis.*
Oyſter Shells.	Lime.	Scurvy-graſs Leaves.
A Piece of Oak.	*Pulvis Aureus.*	*Sal Armoniac* mix'd with Oil of Vitriol.
Indian Wheat.	Brimſtone Matches, burning.	Spirit of Turpentine mix'd with Oil of Vitriol.
Peaſe.	A burning Candle.	Vinegar poured on Oyſter-ſhells.
Muſtard-ſeed.	Living Animals, *e. g.* a Cat.	Lemon Juice.
Amber.	Human Lungs, in breathing.	Ale.
Tobacco.	Filings of Iron, with Spirit of Nitre.	*Malaga* Raiſins.
Oil of Anis-ſeed.	Filings of Iron with Spirit of Hartſhorn.	N. B. *Moſt of the abovementioned Subſtances were in an abſorbing State in cold Weather.*
Oil of Olives.	Filings of Iron with Spirit of *Sal Armoniac.*	
Honey.	N. B. *When a lighted Candle is put into that Air which had been fouled by a Candle burning, and going out in it, tho' it burn'd but a fifth Part of the Time that it had done before, it abſorb'd as much Air: Which ſhews, that Air loaded with Vapours, is more apt to loſe its Elaſticity than clear Air.*	
Newcaſtle Coal.		
Wax.		
Earth.		
Salt.		
Antimony.		
Pyrites from *Walton* Heath.		
Sea-ſalt.		
Nitre.		
Calculus Humanus.		
Vitriol.		
Bones.		
Red Lead.		
Chalk.		
Wheat and Barley.		
Filings of Mercury, with Oil of Vitriol and Water.		

It appeared, by ſeveral Experiments, that the Air which was got out of the Subſtances above-mentioned, was true permanent Air; for it had, and after many Days, continued to have, both the Weight and Elaſticity of common Air, of which a cubick Inch weighs $\frac{2}{7}$ of a Grain; and after it had been compreſſed, it would expand again to its former Dimenſions.

Moſt of that Air has a poiſonous Quality; a Sparrow dying aſſoon as it was put into the Air made of Oak, eleven Days after the ſaid Air had been made. So Mr. *Boyle* found the Air drawn by the Air-pump, from Bread, and ſome other Subſtances, to have a poiſonous Quality.

Air generated by *Indian* Wheat, and by Peaſe, and moſt other Subſtances, flaſh'd when the Candle was apply'd to it.

The moſt ſolid Parts of Animals or *Vegetables*, commonly generated the moſt Air; Oak $\frac{1}{3}$ of its Weight, and 216 times its Bulk; and the Peaſe more than $\frac{1}{3}$ of their Weight, and 396 times their Bulk. But of all Subſtances, a Stone taken from the Bladder of a Man, generated moſt Air; namely, a Quantity of Air 645 times the Bulk, and above half the Weight of the Stone.

Our indefatigable Philoſopher, to judge the better of the Reſult of theſe Experiments, contrived a Gage with a Tube ſealed at one End, and having the other (open End) immerſed in Mercury covered with Honey, which, in the Riſe of the Mercury in the Glaſs, would leave a Mark, to ſhew how far the Mercury had riſen (See the Deſcription and Draught of it in his Book, *Page* 205.) by the Force of compreſſed Air, or of the Air that is generated from ſeveral Subſtances, whilſt confin'd; and propoſes this Gage for meaſuring the Depth of the Sea, which muſt anſwer better than any Contrivance hitherto try'd.

From obſerving that it would require a Force 48 times greater than that of the Atmoſphere, to compreſs the Air that comes out of an Apple into the ſame Space again (which, in an Apple of 16 ſquare Inches Surface, is equal to 11.776 Pounds) he concludes, that the greateſt Part of the ſaid Air muſt be in a fix'd State, and preſerv'd in that State by the Attraction of the Particles of Air and Apple in their Coheſion; otherwiſe Fruits, and all other Subſtances that contain much Air, would be torn to Pieces by its repellent Force, with a greater Exploſion than that of Gunpowder; and therefore that the Air, when extricated, does not conſiſt of fibroſe Particles wound up like little Springs; but of Particles that do not touch one another, but have a repellent Force, which is reciprocally proportionable to the Diſtances of the Particles, agreeable to what Sir *Iſaac Newton* ſays in his *Opticks*, *Query* 31.

The Particles, when they are ſhaken off from Bodies by Heat or Fermentation, ſo ſoon as they are beyond the Reach of the Attraction of the Body, receding from it, as alſo from one another, with greater Strength, and keeping at Diſtance, ſo as ſometimes to take above a Million of times more Space than they did before in the Form of a denſe Body; which vaſt Contraction and Expanſion ſeem unintelligible, by feigning the Particles of Air to be ſpongy and rameous, or rolled up like Hoops, or by any other Means than by a repulſive Power.

Our Author made ſome Experiments upon a Calf's Lungs, which help to confirm Dr. *James Keil*'s Aſſertion, *viz.* That the inner Surface of a Man's Lungs is equal to about 150 ſquare Feet, which is about ten times more than the Surface of the whole Body. Then, by ſeveral Experiments and curious Obſervations, found, that, of the Air which is inſpired by the Lungs in an Hour, *viz.* 48000 cubick Inches, about 353 Inches, or 100 Grains in Weight, are deſtroyed in that Time.

He ſhews, that the Reaſon that ſulphureous Air is pernicious, is, becauſe it loſes its Elaſticity ſo faſt, that the Lungs will ſubſide in it, and the Blood conſequently ſtagnate. He concludes, that when the Particles of ſuch Air are united into pretty large *Moleculæ*, in a fixed State, they are too big to enter into the Veſſels of the Lungs.

He ſhews the Miſtake of thoſe that ſuppoſed the Air did not loſe its Elaſticity, but its *vivifying Spirit*, by Vapours, by an Experiment made upon a Dog, into whoſe Lungs he drove by Force that effete Air which the Dog, by his own Action, could not draw into his Lungs: And whereas the Dog then was juſt expiring by the ſubſiding of his Lungs, he kept him alive by the forcible Impulſion of that very Air, as long as he could blow up the Dog's Lungs with it.

He makes it appear, that a cloſe warm Air, without a Communication with the outward Air, to carry off the Vapours, muſt be unfit for breathing long, and therefore condemns the Uſe of *German* Stoves.

That when Animals are killed by Lightning, without any viſible Wound, it is becauſe the ſulphureous Steams have deſtroy'd the Elaſticity of the Air about them: As appears by diſſecting ſuch Animals, whoſe Lungs are always found compreſſed together, without any Air in them. The ſame alſo appears in Men that have been killed by Damps in Mines.

Then he gives the Deſcription of an Inſtrument, whereby four or five Quarts of the ſame Air (which, in the common Way, can ſerve one Man to breathe very little above a Minute) may ſerve 8 ½ Minutes to breathe, by drawing in the Air, which has been in the Lungs, thro' four Diaphragms of Flannel, dipp'd in a *Lixivium* of highly-calcin'd Salt of Tartar, and afterwards dry'd, and blowing back the ſame Air in ſuch Manner, that it may, at every Inſpiration, return through the ſaid Diaphragms; which is done by Means of two Valves. The Moiſture and ſulphureous Vapours of the Air are, by this Contrivance, ſtopped in paſſing thro' the Flannel, and thereby the Air continues wholeſome much longer than it would in the common Way of breathing: This he propoſes as uſeful to thoſe who have Occaſion to go into Places where the Air is infectious: But where the noxious Vapours are not very denſe, Mufflers only of Cloth or Flannel, impregnated with Salt of Tartar, may ſerve; as he found by ſeveral Experiments.

He ſhews afterwards the Reaſons why *Pulvis Fulminans* has more Force than Gun-powder, and confirms Sir *Iſaac Newton*'s Account of Fire and Flame, (*Query* 9 and 10 of his *Opticks*) but ſhews Dr. *Newentyt*'s, Dr. *Boerhaave*'s, and Monſ. *L'Emery*'s Account of Fire, to be erroneous; but that it was not the Matter of Fire, but elaſtick Air, which that laſt named Gentleman had ſo often obſerv'd to be loſt in the Analyſis of Bodies.

That the artificial Sulphur made by Monſ. *Geoffrey* was inflammable, chiefly on Account of the Air ſupply'd to it by the Oil of Tartar.

That if Fire was a peculiar Matter, it ought to dilate, not to condenſe the Air; as it appears to do by Experiment. That Fire conſiſts in the Action and Re-action between repellent Air and attracting Sulphur; and that Heat is communicated by the ætherial *Medium* mentioned by Sir *Iſaac Newton* in the laſt Edition of his *Opticks*.

That Fermentation will diſſolve Bodies without the Help of included Fire, acting according to its ſeveral Degrees; a lower Degree of it (ſuch as attends every inteſtine Motion) not being inconſiſtent with the healthy State of Plants and Animals.

That acid Particles, by their great attractive Force, diſſolve Bodies ruſhing towards their Particles, ſo as to excite Heat, and ſhake aſunder ſome of them, and turn them into Air.

That Air in a fixed State, is the Bond of Union, which makes Salts durable, and which keeps together the ſolid Parts of *Vegetables*, of Animals, and even Globules of the Blood.

That the Air, in a moiſt State, is ſooner abſorbed by ſulphureous Steam, than in a dry State: For a Candle, which in a dry Receiver burn'd 70 Seconds, burn'd but 64 in the ſame Receiver, when it was filled with the Fumes of hot Water; but yet abſorbed ⅕ Part more of Air. But the abſorbing Subſtances loſe the Force of acting, when united in a large Body; Brimſtone in a Roll abſorbing no Air, tho' it does it ſo plentifully when reduced into minute Particles.

That ſome of the Food of Animals generates, and ſome abſorbs Air; and the Digeſtion in a healthy State is beſt performed, when there is but a little more Air generated than is abſorbed.

From the Conſideration of the ſeveral Experiments made by Dr. *Hales*, in his *Analyſis of Air*, he makes it appear, that our Atmoſphere is a Chaos of different Particles; ſome of which are elaſtick, and ſome unelaſtick; and that the elaſtick Parts are endu'd with very different Degrees of Elaſticity, according as they are bigger or leſs, more or leſs ſolid, more or leſs watry; and therefore, that ſome are eaſily, and ſome more difficultly reducible to a fixed State.

That it is chiefly by the Change of Air, from a fixed to an elaſtick, and from an elaſtick to a fixed State, that this beautiful *Frame of Things* is maintained in a continual Round of the Production and Diſſolution of animal and *vegetable* Bodies; and therefore, that there is as much Reaſon to adopt Air among the chymical Principles, as acid Sulphur, tho' it has hitherto been rejected by the Chymiſts.

VII. *The Author, in this Chapter, applies his ſeveral Experiments and Concluſions drawn from them, to* Vegetation; *and ſhews chiefly the following Things,* viz. *That* Vegetables *are compoſed of Sulphur, Volatile Salt, Water, Earth, and Air.*

That, in Nutrition, the Sum of the attracting Powers of thoſe Subſtances is ſuperior to the Sum of the repellent; and as the watry Vehicle flies off, the Parts harden.

That Oil which is made up of Sulphur and Air, abounds in Seeds, for their better Preſervation.

That in cold Countries, where thoſe Principles are not ſo firmly united, ſmall Wines, ſuch as *Rheniſh*, muſt eaſily yield their Tartar (which, by Experiments, appear to contain Oil and Air); but generous Wines, ſuch as *Madera*, having thoſe Principles more firmly united, will bear a great Degree of Heat before they part with them.

That the Uſe of the Leaves of Trees, is to bring up Nouriſhment within the Reach of the Attraction of the Fruit; to carry off the redundant watry Fluid; to imbibe Rains and Dews which are impregnated with Salt and Sulphur; as likewiſe to imbibe Air, and to be of the ſame Uſe to Plants, as Lungs are to Animals.

Theſe Plants which are over-ſhaded, or too replete with Moiſture, cannot ſo well imbibe Air: Therefore, tho' they will ſhoot out faſt, and have much Wood, they will be more barren in Proportion.

He alſo, by a very ingenious Contrivance, found the Degrees of growing in every Part of young Shoots, which in their growing, extend themſelves moſt in the Middle, and leaſt towards the Top and the Bottom; the ductile, Matter for their Growth being drawn out in Length, like melted Glaſs Tubes, which retain a Hollowneſs, tho' drawn out to the ſmalleſt Thread.

N. B. *In ſome Animals there is ſuch a tough, ductile Subſtance, which hardens when expoſed to the Air in ſmall Threads; as in Spiders and Silk-worms.*

He ſhews, that the Pith ſerves to ſupply the dilating Moiſture for the tender Shoots; but that their Figure may be oblong, and not round, as the Fruit commonly is: There are tough Diaphragms in the Pith, at ſmall Diſtances from each other, which check the lateral Expanſion; as alſo horizontal Fibres, which ſerve for the ſame Purpoſe. And of the ſame Sort is the Pith in the large-growing Feathers of Birds; which is made up of Veſicles that can be diſtended lengthwiſe, but have Splinters at the Ends, to prevent too great a lateral Dilatation.

That the Bones of Animals do not grow at the Joints, (which would prevent their free Motions) but at the *Symphyſis*, *viz.* where the Heads join to the Shanks of the Bones.

That there are particular Veſſels in *Vegetables*, as well as Animals, appropriated for conveying different Sorts of Nutriment; and that where a viſcid Subſtance is to be furniſhed, the Veſſels are lengthened, and often fetch a Compaſs to retard the Velocity of the Fluid, which is to be inſpiſſated into a hard Subſtance. Thus, in hard Stone-fruits, the umbilical Veſſel goes round the Concave of the Stone, and then enters the Kernel near its Cone.

Then at laſt he traces the *Vegetation* of a Plant, from a Seed to a Tree again producing Seed; which Account, as it cannot well be contracted, without leaving out ſomething material, and as it ſerves to ſhew ſome of the excellent Uſes of his happy Diſcoveries, it ſhall be given in his own Words:

Supported by the Evidence of many of the foregoing Experiments, I will now trace the *Vegetation* of a Tree, from its firſt ſeminal Plant in the Seed, to its full Maturity and Production of other Seeds, without entering into a particular Deſcription of the Structure of the Parts of *Vegetables*, which has already been done by Dr. *Grew* and *Malpighi*.

We ſee, by Experiment 56, 57, 58, on diſtilled Wheat, Peaſe, and Muſtard-ſeed, what a wonderful Proviſion Nature has made, that the Seeds of Plants ſhould be well ſtored with very active Principles; which Principles are there compacted together by him, who curiouſly adapts all Things to the Purpoſes for which they are intended, with ſuch a juſt Degree of Coheſion, as retains them in that State till the proper Seaſon of Germination: For if they were of a more lax Conſtitution, they would too ſoon diſſolve, like the other tender annual Parts of Plants; and if they were more firmly connected, as in the Heart of an Oak, they muſt neceſſarily have been many Years in germinating, tho' ſupply'd with Moiſture and Warmth.

When a Seed is ſown in the Ground, in a few Days it imbibes ſo much Moiſture, as to ſwell with very great Forces as we ſee in the Experiment on Peaſe in an Iron Pot. This forcible ſwelling of the Lobes of the Seed *a r*, *a r* (*Fig.* 1.) does probably protrude Moiſture and Nouriſhment from the Capillary Veſſels *r r*, which are called the Seed-roots, into the Radicle *c z d*; which Radicle, when it is thus ſhot ſome Length into the Ground, does then imbibe Nouriſhment from thence; and after it has acquired ſufficient Strength, as this tender ductile Root is extending from *z* to *c*, it muſt neceſſarily carry the expanding Seed-lobes upwards, at the ſame Time that the dilating from *z* to *d* makes it ſhoot downwards; and when the Root is thus far grown, it ſupplies the Plume *b* with Nouriſhment; which thereby ſwelling and extending, opens the Lobes *a r*, *a r*, which are at the ſame Time raiſed above Ground, with the Plume, where they, by expanding and growing thinner, turn to green Leaves (except the Seeds of the Pulſe Kind); which Leaves are of ſuch Importance to the yet tender Plume, that it periſhes, or will not thrive, if they are pulled off: Which makes it probable, that they do the ſame Office to the Plume, that the Leaves adjoining to Apples, Quinces, and other Fruit, do to them, *viz.* they draw Sap within the Reach of their Attraction (ſee *Exper.* 8, 30.) But when the Plume is ſo far advanced in Growth, as to have Branches and expanded Leaves to draw up Nouriſhment, then theſe ſupplemental, ſeminal Leaves *a r*, *a r*, being of no farther Uſe, do periſh; not only becauſe the now grown and more expanded Leaves of the young Plant or Tree do ſo overſhade the ſupplemental Leaves, that the former more plentiful Perſpiration is much abated; and thereby alſo their Power of attracting Sap fails, but alſo becauſe the Sap is drawn from them by the Leaves; and they being thus deprived of Nouriſhment, do periſh.

As the Tree advances in Stature, the firſt, ſecond, third, and fourth Order of the lateral Branches ſhoot out, each lower Order being longer than thoſe immediately above them; not only on the account of Primogeniture, but alſo becauſe being inſerted in larger Parts of the Trunk, and nearer the Root, they have the Advantage of being ſerved with greater Plenty of Sap, whence ariſes the beautiful parabolical Figure of the Tree.

But when Trees ſtand thick together in Woods or Groves, then their natural Shape is altered; becauſe the lower natural Branches being much ſhaded, they can perſpire little; and therefore drawing little Nouriſhment, they periſh: but the top Branches being expoſed to a free, drying Air, they perſpire plentifully; and thereby drawing the Sap to the Top, they advance much in Height. But, *vice verſa*, if when ſuch Grove of tall Trees is cut down, there be left here and there a ſingle Tree, that Tree will then ſhoot out lateral Branches, the Leaves of which Branches now perſpiring freely, will attract Plenty of Sap; on which account, the Top being deprived of its Nouriſhment, it uſually dies.

And as Trees in a Grove or Wood grow only in Length, becauſe all the Nouriſhment is by the Leaves drawn to the Top, moſt of the ſmall, ſhaded, lateral Branches, in the mean time, periſhing for want of Perſpiration and Nutrition; ſo the Caſe is the very ſame in the Branches of a Tree, which uſually making an Angle of about 45 Degrees with the Stem of the Tree, do thereby beautifully fill up, at equal and proper Diſtances, the Space between the lower Branches and the Top of the Tree, forming thereby, as it were, a parabolical Grove or Thicket; which ſhading the Arms, the ſmall lateral Shoots of thoſe Arms uſually periſh, for want of due Perſpiration; and therefore the Arms continue naked, like the Bodies of Trees in a Grove, all the Nouriſhment being drawn up to the Tops of the ſeveral Branches by the Leaves, which are there expoſed to the warm Sun, and free drying Air, whereby the Branches of Trees expand much.

And where the lateral Branches are very vigorous, ſo as to make ſtrong Shoots, and attract the Nouriſhment plentifully, there the Tree uſually abates of its Height: But where the Tree prevails in Height, as in Groves, there commonly its lateral Branches are ſmalleſt: So that we may look upon a Tree as a complicated Engine, which has as many different Powers as it has Arms and Branches, each drawing from their common Fountain of Life, the Root; and the whole of each yearly Growth of the Tree will be proportionable to their attracting Powers, and the Quantity of Nouriſhment the Root affords. But this attracting Power or Nouriſhment will be more or leſs, according to the different Ages of the Tree, and the more or leſs kindly Seaſons of the Year.

And the proportional Growth of their lateral and top Branches, in relation to each other, will much depend on the Difference of their ſeveral attracting Powers.

If the Perſpiration and Attraction of the lateral Branches is little or nothing, as in Woods or Groves, then the top Branches will mightily prevail: but when, in a free open Air, the Perſpiration and Attraction of the lateral Branches come nearer to an Equality with that of the Top, then is the aſpiring of the top Branches greatly checked. And the Caſe is the ſame in moſt other *Vegetables*, which, when they ſtand thick together, grow much in Length with very weak lateral Shoots.

And as the Leaves are thus ſerviceable in promoting the Growth of a Tree, we may obſerve, that Nature has placed the Petals or Leaf-ſtalks where moſt Nouriſhment is wanting to produce Leaves, Shoots, and Fruit, and ſome ſuch thin, leafy Expanſions, which may be called primary Leaves, that ſerve to protect and draw Nouriſhment to the young Shoots and Leaf-buds, before the Leaf itſelf is expanded.

And herein we ſee the admirable Contrivance of the Author of Nature, in adapting her different ways of conveying Nouriſhment to the different Circumſtances of her Productions. For in this Embryo-ſtate of the Buds, a ſuitable Proviſion is made to bring Nouriſhment to them, in a Quantity that is ſufficient for their then ſmall Demands. But when they are in ſome Degree increaſed and formed, a much greater Quantity of Nouriſhment is neceſſary, in proportion to their greater Increaſe: Nature, that ſhe may no longer ſupply with a ſcanty Hand, immediately changes her Method, in order to convey Nouriſhment with a more liberal Hand to her Productions; which Supply daily increaſes by the greater Expanſion of the Leaves, and conſequently the more plentiful Attraction and Supply of Sap, as the greater Growth and Demand for it increaſes.

We find a much more elaborate and beautiful *Apparatus* for the like Purpoſe, in the curious Expanſions of Bloſſoms and Flowers, which ſeem to be appointed by Nature, not only to protect, but alſo to draw and convey a Nouriſhment to the Embryo, Fruit, and Seeds. But as ſoon as the Calyx is formed into a ſmall Fruit, now impregnated, with its minute ſeminal Tree, furniſhed with its *Secundine*, *Chorion*, and *Amnion*, (which new-ſet Fruit may, in that State, be looked upon as a compleat Egg of the Tree, containing its young unhatched Tree, yet in *Embryo*) then the Bloſſom falls off, leaving the new-formed Egg, or firſt-ſet Fruit, in this infant State, to imbibe Nouriſhment ſufficient for itſelf, and the *Fœtus* with which it is impregnated; which Nouriſhment is brought within the Reach and Power of its Suction by the adjoining Leaves.

If I may be allowed to indulge Conjecture, (in a Caſe, in which the moſt diligent Enquirers are, as yet, after all their laudable Reſearches, advanced but little farther than mere Conjecture) I would propoſe it to their Conſideration, whether, from the manifeſt Proof we have, that Sulphur ſtrongly attracts Air, a Hint may not be taken, to conſider, whether this may not be the primary Uſe of the *Farina Fœcundans*, to attract, and unite with itſelf, elaſtick, or other refined active Particles?

That this *Farina* abounds with Sulphur, and that, a very refined Sort, is probable, from the ſubtile Oil, which Chymiſts obtain from the Chives of Saffron. And if this be the Uſe of it, was it poſſible that it could be more aptly placed for the Purpoſe than on very moveable *Apices*, fixed on the ſlender Points of the *Stamina*, whereby it might eaſily, with the leaſt Breath of Wind, be diſperſed in the Air, thereby ſurrounding the Plant, as it were, with an Atmoſphere of ſublimed ſulphureous Pounce? for many Trees and Plants abound with it: Which uniting with the Air Particles, they, or a very ſublimed Spirit from them, may be, perhaps, inſpired at ſeveral Parts of the Plant, and eſpecially at the *Piſtillum*, and be thence conveyed to the *Capſula Seminalis*, eſpecially towards the Evening, and in the Night, when the beautiful *Petala* of the Flowers are cloſed up, and they, with all the other Parts of the *Vegetable*, are in a ſtrongly imbibing State.

And if to theſe united ſulphureous and aërial Particles, we ſuppoſe ſome Particles of Light to be joined, (for Sir *Iſaac Newton* has found, that Sulphur attracts Light ſtrongly); then the Reſult of theſe three, by far the moſt active Principles in Nature, will be a *Punctum Saliens* to invigorate the ſeminal Plant: And thus we are at laſt conducted, by the regular *Analyſis of Vegetable Nature*, to the firſt enlivening Principle of the minuteſt Origin.

VEGETATION, is the Act whereby Plants receive Nouriſhment, and grow: The Word is derived from the Latin, *vegeto* to *quicken*, to *refreſh*, to make *lively and ſtrong*, and ſignifies the Way of Growth, or Increaſe of Bulk, Parts, and Dimenſions proper to all Trees, Shrubs, Herbs, Plants, Minerals, *&c.*

To underſtand the Proceſs of Nature in the Buſineſs of *Vegetation*, it is to be conſidered, that there is in Vegetables a Principle of Life; and this is differently ſeated.

A certain Author ſays; Generally ſpeaking, this Principle of Life is ſeated exactly between the Trunk and the Root; and this is obſerved to be the Place of its Poſition, in all or moſt of the Seminiferous Tribe: For if the *Oak* be included in that general Title, and the Body of it be cut down near the Place, it is Odds if ever it ſhoots again, or at leaſt to any Purpoſe.

In ſome Plants it is only the Roots; ſo that let them be cut into as many Pieces as reaſonably may be, if theſe Pieces are but planted in the Ground, they quickly grow; as is ſeen in the *Elm*, *&c.* and in abundance of edible Roots and Flowers.

In ſome, it is ſeated both in the Roots, and all over the Trunk and Branches; as, in the Vimineous or *Willow* Kinds: which, if they be cut into a thouſand Pieces, it is ſcarce poſſible to deſtroy or kill them, unleſs they are ſplit in the Middle: and ſcarcely then; for if you plant them in the Earth but the Length of three or four Inches, either the Roots or Branches will certainly grow again.

In ſome it is ſeated intirely in the Body, Branches, or Leaves; and of this Kind are many of the exotick Plants, which being of a ſucculent Nature, if the Trunk or Branches, or the Leaves and Stems, be put into the Ground, they will ſtrike Root immediately, and grow; as in the *Cereus's*, *Ficoides's*, *Sedums*, &c. Nay, ſo ſtrong is the Principle of Life in this Kind of Plants, that if they be hung up a conſiderable Time without any Earth, Water, *&c.* they will maintain their natural Verdure, and alſo this Principle of Life admirably, by their ſucculent Quality.

The Uſe of this Principle of Life, is accounted to be for the Concoction of the indigeſted Salts, which aſcend thro' the Roots, where they are ſuppoſed to aſſimilate the Nature of the Tree they are helping to form; though perhaps the Root may likewiſe aſſiſt in the Work.

Theſe Things being preſuppoſed, in the *Spring* of the Year, as ſoon as the Sun begins to warm the Earth, and the Rains do melt the latent Salts, the whole Work of *Vegetation* is ſet on foot; then the emulgent Fibres ſeek for Food, which has been prepared as aforeſaid.

It is very rational to ſuppoſe, that a great Part of the Roots are formed under Ground during the *Winter* Seaſon; becauſe in all Lands there is always an innate Heat, which ſeems to be a natural vital Quality, or nitrous Fermentation.

The Roots, by ſeeking out and aſſuming thoſe nitrous Salts, are immediately (by the Courſe of Nature, and the attractive Virtue of the Sun) drawn upwards to the vital Principle; and after Concoction, do aſcend ſtill higher into the Stem, and break out firſt in the Buds, the ſhelly and tendereſt Part of the whole Machine, and afterwards diffuſe themſelves into the Leaves, Flowers, Fruits, *&c.* which lie invelop'd therein, according to their natural Frames, *&c.*

There are ſome which ſay there are three Kinds of Sap different from each other in Rarefaction and Purity, which aſcend from the Root; from which are compoſed the Branches, Leaves, Flowers, and, conſequent to them, the Fruit; and that they paſs in different Channels.

But others, again, ſuppoſe it is rather all of one Kind; and that it aſſumes its proper Office by an hidden Inſtinct in Nature, juſt as it enters the Boughs or Branches whereon the Fruit is to be; they being, by ſome caſual Sprouts of the laſt Year, already form'd for that Purpoſe; or, probably, that it is rarefy'd by the Paſſage through the Stem.

And there are ſome that do ſuppoſe, that ſubterraneous Fires are concerned in the work of *Vegetation*, or the Growth of Plants: but as, upon the beſt Obſervation that hath been made, none can pretend to have diſcovered any Heat or Fumigation to iſſue from the Surface of the Bowels of the Earth, adequate to the meaneſt artificial Fire; it is plain, that the Sun is the Principle, and ſo may be called the Father, of *Vegetation*, and the Earth the Mother; the Rain and Air being neceſſary Co-efficients in this ſurprizing Work. See the Articles *Sun*, *Earth*, *Air*, *Rain*.

Another Author tells us, That as in animal Bodies there are ſeveral Degrees of Juices, which are refined more or leſs, as the Veſſels they paſs through are larger or ſmaller, or perhaps according to their Figure; ſo alſo Plants are found to have Veſſels of different Functions, which do, like Filtres of different Kinds, ſeparate and alter the Juices which paſs through them; ſo that they may be diſtinguiſhed ſeparately by the Senſes, altho' they do all originally proceed from the ſame Fund of indigeſted Juice in the Root: And by how much theſe Juices have the more Time to open and nouriſh the ſeveral Parts they paſs through; by ſo much, as well the Parts as the Juices, become more perfect, and approach nearer to the Point of Maturity, which is fixed by Nature for their Perfection. In this Progreſs, thoſe Parts which are to be acted upon, ripen equally, as thoſe do that are to act.

It is apparent, by the Uſe of Microſcopes, that Plants conſiſt of different Parts, Veſſels, *&c.* analogous to thoſe of Animals; and each Kind of Veſſel is ſuppoſed to be the Vehicle of a different Humour, or Juice, ſecreted from the Matter of the Sap; which is conſidered as the Blood or Common Fund of them all.

Dr. *Grew* farther explains this, by ſaying, That all Kinds of *vegetable* Principles are at the firſt received together in a Plant, and are ſeparated afterwards; *i. e.* they are filtred ſome from others, in very different Proportions and Conjunctions by the ſeveral Parts; ſo every Part is the Receptacle of a Liquor, become peculiar, not by any Transformation, but only by the Percolation of Parts out of the common Maſs or Stock of Sap; and thoſe that are ſuperfluous in any Plant, are diſcharged back by Perſpiration.

The ſame Author aſſigns the Offices of the ſeveral Veſſels: He calls thoſe Veſſels *Lymphæducts*, which are placed on the inner Verge of the Bark; and theſe, he ſuppoſes, are appointed for the Conveyance of the moſt aqueous or watry Liquor.

Thoſe Veſſels that are in the Middle of the Plant, he calls *Lactiferous*, or *Reſiniferous*; theſe he takes to be the principal *Viſcera* of Plants; and that as the *Viſcera* of *Animals* are but conglomerated Veſſels, ſo the *Viſcera* of *Plants* are Veſſels drawn out at Length.

It is alſo remarkable in many Caſes, That the Multitude and Largeneſs of the Veſſels do produce a ſweet and vinous Sap; and the Fewneſs and Smallneſs of the Veſſels produce an oily and aromatick Sap.

It ſeems neceſſary, to the Nutrition of Plants, as well as Animals, that there be a Concurrence of two ſpecifically diſtant Fluids: And a certain Author maintains, That there is an Intermixture of two ſuch Humours in every Part of a Tree; every Part of Sap being impregnated with other Tinctures, and continually filtred from Fibres of one Kind to thoſe of another; and from this Mixture many of the Phænomena of the Ripening, Odour, Colours, *&c.* are accounted for.

With regard particularly to the Odours in Plants, Dr. *Grew* is of Opinion, that they chiefly proceed from the Air-veſſels that are in the Wood; not but that the other Parts do alſo yield their Smells, which is moſt plain to be perceived in Plants that are freſh, undry'd, and unbruiſed: For he ſays, that the Air bringing along with it a Tincture from the Root, and from the ſeveral organical Parts, and at laſt entering the Concave of the Air-veſſels, it conſiſts there.

Another Writer ſays, That it cannot be denyed, but the *Effluvia*, which can be admitted into the Wood-veſſels, may give a Smell to the Wood: but however, as that Vapour paſſes through Veſſels which have a different Structure, ſo as to alter the Form of its Parts; ſo in every one of its Changes it will yield a Smell different from the reſt; the Smell of the Wood will differ from that of the Bark, the Juices in the one being more eſſential than the other; but yet both being bruiſed and mixed together, yield a Scent different from either of them ſingly; and likewiſe the Leaves give a Scent that is different from either of the former; and ſo alſo do the Flowers from that in the Leaves, and alſo the Fruit from that in the Flowers.

Dr. *Grew* is of Opinion, that the chief governing Principle in the Juice of Plants, is the *Saline*; which *ſaline* Principle, he ſays, muſt be underſtood as a *generick* Term, under which divers Species are comprehended. The *vegetable* Salts ſeem to be four; *viz.* the *nitrous* and the *acid*, *alkaline* and *marine*; and of theſe, the *nitrous Salts* ſeem to be aſſigned by Nature chiefly for the Growth of Plants.

The curious *Malpighius* has very accurately delivered the Proceſs of Nature in the *Vegetation of Plants*, to the Effect following:

The *Ovum* or Seed of the Plant being excluded out of the *Ovary*, (which is called the *Pod* or *Husk*) and requiring farther foſtering and brooding, is committed to the Earth.

Where the Earth, like a kind Mother, having received it into her Boſom, does not only perform the Office of Incubation, by her own warm Vapours and Exhalations, in Conjunction with the Heat of the Sun, but gradually ſupplies what the Seed requires to its farther Growth, as abounding every-where with Canals and Sinus's, in which the Dew and Rain-water, impregnated with fertil Salts, glide like the Chyle and Blood in the Arteries, &c. of Animals.

This Moiſture meeting with the new depoſited Seed, is percolated or ſtrained through the Pores or Pipes of the outer Rind or Huſk (anſwering the *Secundines* of *Fœtus's*); on the Inſide whereof lie one or more, commonly two, thick ſeminal Leaves (correſponding to the *Placenta* in Women, and the *Cotyledons* in Brutes.)

Theſe Seed-leaves conſiſt of a great Number of little *Veſiculæ* or Bladders, with a Tube correſponding to the Navel-ſtrings in Animals.

The Moiſture of the Earth ſtrain'd through the Rind of the Seed, is received into theſe *Veſiculæ*; which cauſes a ſlight Fermentation with the proper Juice before contain'd therein.

This fermented Liquor is conveyed by the Umbilical Veſſel to the Trunk of the little Plant, and to the Gem or Bud which is contiguous to it; upon which a *Vegetation* and Increaſe of the Plant ſucceeds.

This Procedure in the *Vegetation* of Plants, the aforeſaid Author exemplifies in a Grain of *Wheat*, as follows:

The *firſt* Day the Grain is ſown, it grows a little turgid, and the *Secundine* or Huſk gapes a little in ſeveral Places; and the Body of the Plant being continued by the Umbilical Veſſel to a conglobated Leaf, (which is call'd the Pulp or *Fleſh* of the Seed, and is what conſtitutes the Flower) ſwells, by which Means, not only the Gem or Sprout (which is to be the future Stem) opens and increaſes, but the Roots begin to bunch out: whence the *Placenta* or Seed-leaf becoming looſe, gapes.

The *ſecond* Day, the *Secundine* or Huſk being broken through, the Stem or Top of the future Straw appears on the Outſide thereof, and grows upwards by Degrees.

In the mean time the Seed-leaf, guarding the Roots, becomes turgid with its *Veſiculæ*, and puts forth a white Down, and the Leaf being pull'd away, you ſee the Roots of the Plant bare; the future Bud, Leaves, and the reſt of the Stalk, lying ſtill hid: Between the Roots and the aſcending Stem, the Trunk of the Plant is knit by the Navel-knot to the Flower-leaf; which is very moiſt, though it ſtill retains its white Colour, and its natural Taſte.

The *third* Day, the Pulp of the conglobated or round Leaf becomes turgid with the Juice it has received from the Earth fermenting with its own.

Thus the Plant increaſes in Bigneſs, and in its Bud or Stem becomes taller, and from whitiſh turns greeniſh: The lateral Roots alſo break forth greeniſh and pyramidal, from the gaping Sheaf, which adheres cloſely to the Plant; and the lower Root grows longer and hairy, with many Fibres growing out of the ſame.

Indeed, there are hairy Fibres hanging all along on all the Roots, except on the Tops; and theſe Fibres are ſeen to wind about the ſaline Particles of the Soil, little Lumps of Earth, &c. like *Ivy*, whence they grow curl'd: About the lateral Roots, there now break out two other little ones.

The *fourth* Day the Stem mounting upwards, makes a right Angle with the ſeminal Leaf: The laſt Roots put forth more; and the other three growing larger, are cloathed with more Hairs, which ſtraitly embrace the Lumps of Earth; and where they meet with any Vacuity, unite into a Kind of Net-work: The Conglobate or Flower-leaf, is now ſofter, and, when bruiſed, yields a white, ſweetiſh Juice, like Barley-cream. By ſtripping it off, the Root and Stem of the Plant are plainly ſeen, with the intermediate Navel-knot, whoſe outer Part is ſolid, like a Bark, and the inner more ſoft and medullary.

The *fifth* Day, the Stalk ſtill riſing, puts forth a permanent or ſtable Leaf, which is green and folded: The Roots grow longer, and there appears a new Tumour of a future Root: The Outer or Sheath is looſened, and the Seed-leaf begins to fade.

The *ſixth* Day, the Stable Leaf being looſened, the Plant mounts upwards, the Sheaf ſtill cleaving round it like a Bark: The Seed-leaf is now ſeen ſinuous or wrinkled and faded; and this being freed or cut from the *Secundine*, the Fleſh or *Pericarpium* is found of a different Texture: The Outer Part, whereby the Outſide of the Seed or Grain is heaved up, being more ſolid; but the Inſide viſcular and full of Humour, eſpecially that Part next the Navel-knot. All the Leaves being pulled off, the Roots torn, and the Flower-leaf removed, the Trunk appears; wherein, not far from the Roots, the Navel-knot bunches out, which is ſolid, and hard to cut: Above there is the Mark of the Sheath-leaf, which was pulled off; and underneath, as in an Arm-pit, the Gem is often hid: the hind Part of the Plant ſhews the breaking forth of the Roots likewiſe, with the faded *Placenta*, &c.

After the *eleventh* Day, the Seed-leaf, as yet ſticking to the Plant, is crumpled and almoſt corrupted; within, it is hollow; and about the *Secundine*, the mucous and white Subſtance of the Seed being continued to the Navel-knot, forms a Cavity: All the Roots becoming longer, put forth new Branches out of their Sides. The ſecond Leaf withers, and its Veſicles are emptied: The Internodes or Spaces between the Knots grow longer; new Gems appear, and the middle Root grows ſeveral Inches long.

After a Month, the Roots and Stalk being grown much longer, new Buds break out at the firſt Knot, and little Tumours bunch out, which, at length, break out into Roots.

As to the *vegetable Matter*, or the Food where the Plants grow, there is ſome Doubt: It hath been a general Opinion amongſt almoſt all the modern Naturaliſts, That the *Vegetation* of Plants, and even of Minerals too, is principally owing to Water, which not only ſerves as a Vehicle to convey to them the fine rich Earth, &c. proper for their Nouriſhment; but being tranſmuted into the Body of the Plant, affords the greateſt Part, if not all the Matter with which they are nouriſhed, and by which they grow and increaſe in Bigneſs. This Opinion is countenanced by very great Names; particularly by the ingenious Doctor *Woodward*, who, in order to aſcertain this Point, made the following Experiments:

In the firſt Place, he carefully examined all Sorts of Water, and found, that the cleareſt, fineſt Spring-water, which he could any-where meet with, exhibited even to the naked Eye, great Numbers of exceeding ſmall terreſtrial Particles; and that all other craſſer Waters had theſe in yet much greater Quantity; and alſo, that they were of a larger Bulk.

He found this terreſtrial Matter contain'd in all Water to be of two Kinds: The one properly a *vegetable Matter*, but conſiſting of very different Particles; ſome of which are very proper for the Nouriſhment of ſome Kinds of Plants; others for different Sorts, &c. The other Kind of earthy Matter he found to be purely of a mineral Nature; and this alſo was of very various and different Kinds.

The former Sort of *vegetable* earthy Matter abounds plentifully in all Waters; but for the mineral, it is found moſtly in Spring-water; next to that, in River-water; and leaſt of all, in Rain-water: though even there alſo it is to be found plentifully.

This Fact, he ſays, any one may diſcover, by only keeping Water for a competent Time without ſtirring it, in a clear Glaſs Phial, cloſely ſtopp'd to keep out Duſt, &c. for then he will obſerve, that theſe very ſmall terreſtrial Particles, which before were ſcarcely viſible ſingly, will now combine together into large and more conſpicuous Maſſes, which, by Degrees, will join together, and form Clouds, as it were, in the Water, which will grow daily more and more opacous and thick by the continual Acceſſion of new Matter: And if the earthy Matter in the Water be chiefly of the *vegetable* Kind, it will turn the Water green, the uſual Colour of *Vegetables*; and this will grow deeper and deeper-colour'd, but will not precipitate to the Bottom of the Glaſs, as the Mineral Water will, if there be any conſiderable Quantity, by reaſon of its much greater ſpecifick Gravity. On the Whole therefore he concludes very juſtly, That there is in all Water a conſiderable Quantity of the earthy Matter. And in order to determine whether the *Vegetation* of Plants was chiefly owing to bare Water or not, rather than to the *terreſtrial Matter* therein contain'd, he made, with very great Accuracy and Care, ſeveral Experiments.

Which Experiments, becauſe they were done with an uncommon Care and Exactneſs, and are follow'd by very ingenious *Reflections*, ſerving to explicate many Difficulties of Philoſophy, and to ſet the whole Affair of *Vegetation* in a very good Light; I ſhall give the Regiſter of as follows.

Anno Dom. 1691, he choſe ſeveral Glaſs Phials that were all, as near as poſſible, of the ſame Shape and Bigneſs. After he had put what Water he thought fit into every one of them, and taken an Account of the *Weight* of it, he ſtrain'd and ty'd over the Orifice of each Phial a Piece of Parchment, having Holes in the Middle of it large enough to admit the Stem of the Plant he deſigned to ſet into the Phial, without confining or ſtraitening it ſo as to impede its Growth. His Intention in this, was to prevent the incloſed Water from evaporating or aſcending any other Way than only through the Plant to be ſet therein.

Then he made Choice of ſeveral Sprigs of *Mint*, and other Plants, that were, as near as he could poſſibly judge, alike ſound, freſh, and lively: Having taken the Weight of each, he placed in a Phial, ordered as above; and as the Plant imbibed and drew off the Water, he took Care to add more of the ſame from time to time, keeping an Account of the Weight of all he added. Each of the Glaſſes were, for better Diſtinction, and the more eaſy keeping a Regiſter of all the Circumſtances, noted with a different Mark or Letter, as A, B, C, *&c.* and all ſet in a Row in the ſame Window, in ſuch manner that all might partake alike of Air, Light, and Sun.

Then they continu'd from *July* 20th to *October* the 5th, which is juſt 77 Days, when he took them out, weighed the Water in each Phial, and the Plant likewiſe, adding to its Weight that of all the Leaves that had fallen off, during the time it had ſtood thus: And, laſtly, he computed how much each Plant had gain'd; and how much Water was ſpent upon it.

The Particulars are as follow:

The Plant weigh'd, when put in, *July* the 20th, juſt 27 Grains: When taken out, *October* the 5th, 42 Grains. So that in the Space of 77 Days, it had gain'd in Weight 15 Grains.

The whole Quantity of Water expended during the 77 Days, amounts to 2558 Grains. Conſequently the Weight of the Water taken up, was 170 $\frac{8}{5}$ times as much as the Plant had gain'd in Weight.

This will be made plainer by the following TABLES.

Weight of the Plant when firſt put into Water.	Weight of the Plant when taken out of the Water.	Weight gain'd by the Plant during the 77 Days.	Weight of the Water expended upon the Plant.	Proportion of the Increaſe of the Plant to the Expence of the Water.
		A		
		Common Spear-Mint.	*Spring-Water.*	
27 *Grains.*	42 *Grains.*	15 *Grains.*	2558 *Grains.*	*as* 1 *to* $170\frac{8}{15}$.
		B		
		Common Spear-Mint.	*Rain-Water.*	
$28\frac{1}{4}$ *Grains.*	$45\frac{3}{4}$ *Grains.*	$17\frac{1}{2}$ *Grains.*	3004 *Grains.*	*as* 1 *to* $171\frac{23}{35}$.
		C		
		Common Spear-Mint.	*Thames-Water.*	
28 *Grains.*	54 *Grains.*	26 *Grains.*	2493 *Grains.*	*as* 1 *to* $95\frac{23}{26}$.
		D		
		Common Solanum or *Nightſhade.*	*Spring-Water.*	
49 *Grains.*	106 *Grains.*	57 *Grains.*	3708 *Grains.*	*as* 1 *to* $65\frac{3}{57}$.
		E		
		Lathyrus ſeu *Cataputia.*	*Ger. Spring-Water.*	
98 *Grains.*	$101\frac{1}{2}$ *Grains.*	$3\frac{1}{2}$ *Grains.*	2501 *Grains.*	*as* 1 *to* $714\frac{4}{7}$.

The Specimen D had ſeveral Buds upon it, when firſt ſet into the Water; theſe, in ſome Days, became fair *Flowers*, which were at length ſucceeded by Berries. Several other Plants were try'd, which did not thrive in Water, nor ſucceed any better than the *Cataputia* foregoing.

The Phials F and G were fill'd, the former with *Rain*, and the other with *Spring-Water*, at the ſame time as thoſe abovementioned were, and ſtood as long as they did; but they had neither of them any Plant: the Deſign of which was, in order to learn, whether any Water exhaled out of the Glaſſes, otherwiſe than through the Bodies of the Plants.

The Orifices of theſe two Glaſſes were cover'd with Parchment, each Piece of it being perforated with a Hole of the ſame Bigneſs with thoſe of the Phials above. In theſe was ſuſpended a Bit of Stick about the Thickneſs of the Stem of one of the aforeſaid Plants, but not reaching down to the Surface of the incloſed Water, that the Water in theſe might not have more Scope to evaporate than that in the other Phials.

Thus they ſtood the whole 77 Days with the reſt, when, upon Examination, none of the Water was found to be waſted or gone off; tho' he obſerv'd, both in theſe and the reſt, eſpecially after very hot Weather, ſmall Drops of Water, not unlike to Dew, adhering to the Inſides of the Glaſſes, *i. e.* that Part of them that was above the Surface of the incloſed Water.

The Water in theſe two Glaſſes that had no Plants in them, at the End of the Experiment exhibited a larger Quantity of terreſtrial Matter than that in any of thoſe that had the Plants in them did.

The Sediment in the Bottom of the Phials was greater, and the *Nubucelæ* diffus'd thro' the Body of the Water, thicker: And of that which was in the others, ſome of it proceeded from certain ſmall Leaves that had fallen from that Part of the Stem of the Plants that was within the Water, wherein they rotted and diſſolv'd.

The Terreſtrial Matter in the Rain-Water was finer than that in the Spring-Water.

Experiments, Anno 1692.

The Glaſſes made uſe of in this, were of the ſame Sort with thoſe of the former Experiment, and cover'd over with Parchment after the ſame manner.

The Plants here were all *Spear-Mint*, the moſt kindly, freſh, ſprightly Shoots he could chuſe. The Water and Plants were weighed, as above; and the Phials ſet in a Line, in a *South* Window, where they ſtood from *June* 2d to *July* 28th, which was juſt 56 Days.

The Plant H, was all along a very kindly one, and ran up about two Feet in Height. It had ſhot but one conſiderable collateral Branch, but had ſent forth many and long Roots; from which ſprung very numerous, tho' ſmall and ſhort leſſer Fibres. The leſſer Roots came out of the larger on two oppoſite Sides for the moſt part; ſo that each Root, with its *Fibrillæ*, appears not unlike a ſmall Feather. To theſe *Fibrillæ* adhered pretty much *terreſtrial Matter:* In the Water, which was at laſt thick and turbid, was a green Subſtance, reſembling a fine thin *Conſerva*.

The Plant I, was as kindly as the former, but had ſhot no collateral Branches: Its *Roots*, the *Water*, and the green Subſtance, all much as in the former.

The Plant K, though it had the Misfortune to be annoy'd with very ſmall Inſects, that happen'd to fix upon it, yet had ſhot very conſiderable collateral Branches, and at leaſt as many Roots as either H or I, which had a much greater

Weight of the Plant when first set in Water.	Weight of the Plant when taken out of the Water.	Weight gain'd by the Plant when it had stood 56 Days.	Weight of the Water expended upon the Plant.	Proportion of the Increase of the Plant to the Expence of the Water.

Quantity of *terreſtrial Matter* adhering to the Extremities of them. The ſame green Subſtance here, that was in the two preceding.

The Plant L was far more flouriſhing than any of the preceding, had ſeveral conſiderable collateral Branches, and very numerous Roots, to which *terreſtrial Matter* adhered very copiouſly.

The Earth in both theſe Glaſſes was very ſenſibly and conſiderably waſted, and leſs than when firſt put in. The ſame Sort of green Subſtance here, as in thoſe above.

The Plant M was pretty kindly; had two ſmall collateral Branches, and ſeveral Roots, tho' not ſo many as thoſe in H or I: But as much *terreſtrial Matter* adhering to them as thoſe had: The Water was pretty thick, having very numerous ſmall *terreſtrial Particles* ſwimming in it, and ſome Sediment at the Bottom of the Glaſs. This Glaſs had none of the green Matter above-mention'd in it.

The Plant N was very lively, and had ſent out ſix collateral Branches, and many Roots; but the Water was very turbid, and as high colour'd as ordinary Beer.

The Glaſs O had alſo *Hyde-park Conduit Water*, in which was diſſolved a Dram of *Nitre*. The *Mint* ſet in this, ſuddenly began to wither and decay, and died in a few Days; as likewiſe did two more Sprigs that were ſet in it ſucceſſively. In another Glaſs, he diſſolved an Ounce of good Garden Mould, and a Dram of *Nitre*; and in a third, half an Ounce of Wood-aſhes, and a Dram of *Nitre*: But the Plants in theſe ſucceeded no better than the former. In other Glaſſes, he diſſolved ſeveral other Sorts of Earth, Clay, Marles, and Variety of Manures, *&c.* and he ſet *Mint* in diſtill'd *Mint-water*, and made other Experiments of ſeveral Kinds, in order to get a Light and Information what haſtened or retarded, promoted or impeded *Vegetation*.

The Glaſs P, *Hyde-park Conduit Water*: In this he fixed a Glaſs Tube ten Inches long, the Bore one-ſixth of an Inch diameter, filled with very fine and white Sand, which he kept from falling down out of the Tube into the Phial, by tying a fine Piece of Silk over that End of the Tube that was downwards. Upon Immerſion of the lower End of it into the Water, this, by little and little, aſcended quite up to the Orifice of the Tube: And yet in all the 56 Days that it ſtood thus, a very inconſiderable Quantity of Water had gone off, *viz.* ſcarcely 20 Grains, tho' the Sand continued moiſt up to the Top till the very laſt.

The Water had imparted a green Tincture to the Sand, quite to the very Top of the Tube: And in the Phial it had precipitated a greeniſh Sediment, mix'd with black. To the Bottom and Sides of the Tube, as far as it was immerſed in the Water, adhered pretty much of the green Subſtance deſcribed above.

Other like Tubes he filled with *Cotton*, *Lint*, *Pith of Elder*, and ſeveral other porous *vegetable Subſtances*; ſetting ſome of them in clear Water, others in Water tinged with *Saffron*, *Cochineal*, &c, and ſeveral other Trials were made, in order to give a mechanical Repreſentation of the Motion and Diſtribution of the Juices in Plants, and of ſome other *Phænomena* obſervable in *Vegetation*.

Several Plants being alſo ſet in the Phials Q, R, S, *&c.* ordered in like Manner as thoſe above, in *October*, and the following colder Months; theſe throve not near ſo much; nor did the Water aſcend in nigh the Quantity it did in the hotter Seaſons, in which the before-cited Trials were made.

The Reſult of all which *Experiments* he gives us in the following Obſervations and Reflections.

I. *In Plants of the ſame Kind, the leſs they are in Bulk, the ſmaller Quantity of the fluid Maſs, in which they are ſet, is drawn off: The Conſumption, where the Maſs is of equal Thickneſs, being pretty nearly proportioned to the Bulk of the Plant.*

In Effect, the Water ſeems to aſcend up the Veſſels of the Plants, in much the ſame Manner as up a Filtre; and it is not to be wondered at, that the larger Filtre ſhould draw off more Water than the ſmaller; or that a Plant that hath more or larger Veſſels, ſhould take up a greater Part of the Fluid in which it is ſet, than one that has fewer can: Nor is it thus noted as a Thing very conſiderable in itſelf, but chiefly with regard to what follows.

II. *Much the greater Part of the fluid Maſs thus drawn off, and convey'd into the Plant, does not ſettle or abide there, but paſſes thro' their Pores, and exhales up into the Atmoſphere.*

That the Water, in theſe *Experiments*, aſcended only thro' the Veſſels of the Plants, is certain; ſince ſome Glaſſes which had no Plants in them, tho' diſpoſed in the like Manner as the reſt, did remain, at the End of the Experiment, as at firſt, and without any Diminution of Water; and that the greateſt Part of it flies off from the Plant into the Atmoſphere, is as certain.

The leaſt Proportion of the Water expended, was to the Augment of the Plant as 46 or 50 to 1; and in ſome 100, 200 to 1, nay 700 to 1.

Thus ſo continual an Emiſſion of Water, in ſo great Plenty, from the Parts of the Plant, affords a manifeſt Reaſon, why Countries that abound with Trees, and the larger *Vegetables* eſpecially, ſhould be very obnoxious to Damps, great Humidity in the Air, and more frequent Rains, than others that are more open and free.

The great Moiſture of the Air, was a great Inconvenience and Annoyance to thoſe who firſt ſettled in *America*, which, at that Time, was over-grown with Woods and Groves: But as theſe were burnt down and deſtroy'd, to make way for Habitations, and Culture of the Earth, the Air mending, changed into a Temperature more ſerene and dry than before.

Nor does this Humidity go off pure and alone, but uſually carries with it many Parts of the ſame Nature with thoſe whereof the Plant conſiſts: The Craſſer indeed, are not ſo eaſily borne up into the Atmoſphere, but are uſually depoſited on the Surface of the Leaves, Flowers, and other Parts of the Plants; whence proceed our *Manna's*, our *Honey's*, and other gummous Exudations of *Vegetables*: But the finer and lighter Parts are with greater Eaſe ſent up into the Atmoſphere; thence they are convey'd to our Organs of Smelling, by the Air we draw in Reſpiration; and are pleaſant or offenſive, beneficent or injurious to us, according to the Nature of the Plants from whence they ariſe. And ſince theſe owe their Riſe to the Water that aſcends out of the Earth thro' the Bodies of Plants, we cannot be far to ſeek for the Cauſe why they are more numerous in the Air, and a greater Quantity of Odours is found exhaling from *Vegetables* in warm humid Seaſons, than in any other.

III. *A great Part of the terreſtrial Matter that is mixed with Water, aſcends up into the Plant, as well as the Water.*

There was much more terreſtrial Matter at the End of the Experiment, in the Water of the Glaſſes that had no Plants in them, than in thoſe that had Plants. The Garden Mould diſſolved in ſome of the Glaſſes was conſiderably diminiſh'd and carry'd off; nay, the terreſtrial and *vegetable* Matter was borne up in the Tubes filled with Sand, Cotton, *&c.* in that Quantity, as to be evident even to Senſe; and the Bodies in the Cavities of the other Tubes, that had their lower Ends immerſed in Water, wherein Saffron, Cochineal, *&c.* had been infuſed, were tinged with Yellow, Purple, *&c.*

To look abroad a little towards our Shores and Parts within the Verge of the Sea, theſe will preſent us with a large Scene of Plants, that, along with the *vegetable*, take up into them mere mineral Matter alſo, in great abundance; ſuch as our *Sea-purſlain*, ſeveral Sorts of *Algas*, of *Samphires*, and other marine Plants: Thoſe contain common Sea Salts, which are the ſame as the Foſſil, in ſuch Plenty, as not only plainly to be diſtinguiſhed on the Palate, but may be drawn out of them in conſiderable Quantity: Nay, ſome affirm, there are Plants found, that will yield Nitre, and other Mineral Salts.

The *vegetable* Matter being very fine and light, is ſurpriſingly apt and diſpoſed to attend Water in all its Motions, and follow it into each of its Receſſes; as appears not only from the Inſtances above alledged, but many others: Percolate it with all the Care imaginable, filtre it with ever ſo many Filtrations, yet ſome terreſtrial Matter will remain.

Dr. *Woodward* has filtred Water thro' ſeveral Sheets of thick Paper, and after that, through very cloſe fine Cloth, twelve times double, and this over and over, and yet a conſiderable Quantity of this Matter diſcover'd itſelf in the Water after all.

Now, if it thus paſſes Interſtices that are ſo very ſmall and fine, along with the Water, it is leſs ſtrange it ſhould attend it in its Paſſage through the Ducts and Paſſages of Plants. It is true, filtring and diſtilling of Water interrupts and makes it quit ſome of the earthy Matter it was before impregnated withal; but then that which continues with the Water after this, is fine and light, and ſuch, conſequently, as is in a peculiar Manner fit for the Growth and Nouriſhment of *Vegetables*.

And this is the Caſe of Rain Water: The Quantity of terreſtrial Matter it bears up into the Atmoſphere is not great; but what it doth bear up is chiefly of that light Kind of *vegetable* Matter, and that too perfectly diſſolved, and reduced to ſingle Corpuſcles, all fit to enter the Tubes and Veſſels of Plants; on which Account it is, that this Water is ſo very fertil and prolifick.

The Reaſon why all the terreſtrial Matter mix'd with the Water does not aſcend into that, is, that the mineral Matter makes a great deal of it, which is not only groſs and ponderous, but ſcabrous and inflexible, and ſo not diſpoſed to enter the Pores of the Roots; beſides, a great many of the ſimple *vegetable* Particles do by Degrees unite and form ſmall Clods, or *Moleculæ*, which ſtick to the Extremities of the Roots of thoſe Plants; and others of them, entangled in a looſer Manner from the *Nubeculæ*, or green Bodies, ſo commonly obſerved in ſtagnant Water: Theſe, when thus conjoined, are too big to enter the Pores or aſcend up the Veſſels of Plants, which, ſingly, they might have done.

Hence it is that in Agriculture, be the Earth never ſo rich, good, and fit for the Production of Corn, or other *Vegetables*, little will come of it, unleſs the Particles be ſeparated and looſe; and 'tis on this Account ſuch Pains are beſtowed in the digging, tilling, ploughing, fallowing, harrowing, and breaking the clodded Lumps of Earth: And 'tis the ſame Way that Sea Salt, Nitre, and other Salts promote *Vegetation*.

Some Authors imagine Nitre eſſential to Plants, and that nothing in the *vegetable* Kingdom is tranſacted without it; but Dr. *Woodward* ſays, by all the Trials he has been able to make, the Thing ſeems to him quite otherwiſe; and when contiguous to the Plant, Nitre rather deſtroys than nouriſhes it.

But Nitre and other Salts do certainly looſen the Earth, and ſeparate the concreted Parts of it; by that Means fitting and diſpoſing them to be aſſumed by the Water, and carry'd up into the Seed or Plant for its Formation and Increaſe.

It is evident to Obſervation, how apt all Sorts of Salts are to be wrought upon by Moiſture, how eaſily they run with it; and when theſe are drawn off, and have deſerted the Lumps with which they are incorporated, thoſe muſt moulder immediately, and fall aſunder in courſe.

The hardeſt Stone that is to be met with, if it happens, as it frequently does, to have any Salt intermixed with the Sand of which it conſiſts, upon its being expoſed to a humid Air, in a ſhort Time diſſolves and crumbles all to Pieces, and much more will clodded Earth or Clay, which is not of ſo compact and ſolid a Conſtitution.

Lime likewiſe is in the ſame Way ſerviceable in this Affair. The Huſbandmen ſay, it does not fatten, but only mellows the Ground; by which they mean, it doth not contain any Thing in itſelf that is of the ſame Nature with the *vegetable* Mould, or afford any Matter fit for the Formation of Plants, but merely ſoftens and relaxes the Earth; by that Means rendering it more capable of entering the Seeds and *Vegetables* ſet in it, in order to their Nouriſhment, than otherwiſe it would have been.

The Properties of *Lime* are well known, and how apt it is to be put in a Ferment and Commotion by Water; nor can ſuch Commotion ever happen, when Lime is mix'd with Earth, however hard and clodded it may be, without opening and looſening it.

IV. *The Plant is more or leſs nouriſhed, in Proportion as the Water in which it ſtands, contains a greater or ſmaller Quantity of proper terreſtrial Matter in it.*

The Truth of this Propoſition is diſcernible through the whole Proceſs of the Doctor's Experiments. The Mint in one of the Glaſſes was of much the ſame Bulk and Weight with that of two others; but the Water in which the firſt was, being River Water, which was apparently more copiouſly ſtored with terreſtrial Matter, than the Spring or Rain Water, in which the others ſtood, occaſioned it to arrive at almoſt double the Bulk that either of them had, and with a leſs Expence of Water too.

So likewiſe the Mint in another Glaſs, in the Water of which was diſſolved a ſmall Quantity of good Garden Mould; tho' it had the Diſadvantage to be leſs, when firſt ſet, than either of the Mints in the two other Glaſſes, the Water in which was the very ſame as the firſt, only had none of the Earth mix'd with it, yet in a ſhort Time the Plant not only overtook, but much out-ſtripped the other.

The Reaſon why the Proportion of the Increaſe of the Plant was limited to the Quantity of proper terreſtrial Matter in the Water, is, that all, even *vegetable* Matter, is not proper for the Nouriſhment of every Plant: Nor do there want good Indications, that every Kind requires a peculiar and ſpecifick Matter for its Formation and Nouriſhment; yea, each Part of the ſame *Vegetable*; and that there are very many, and different Ingredients, to go to the Compoſition of the ſame individual Plant.

If therefore the Soil wherein any *Vegetable* or Seed is planted, contains all, or moſt of theſe Ingredients, and thoſe in due Quantity, it will grow and thrive, otherwiſe it will not: If there be not as many Sorts of Corpuſcles, as are requiſite for the Conſtitution of the main and more eſſential Parts of the Plant, it will not proſper at all; if there are theſe, and not in ſufficient Plenty, it will never arrive to its natural Stature: Or if any of the leſs neceſſary and eſſential Corpuſcles are wanting, there will be ſome Failure in the Plant; it will be defective in Smell, Taſte, Colour, or ſome other Way.

Indeed it is inconceivable, how one uniform, homogeneous Matter, having its Principles or original Parts of the ſame Subſtance, Conſtitution, Magnitude, Figure and Gravity, ſhould conſtitute Bodies ſo unlike, in all thoſe Reſpects, as *Vegetables* of different Kinds are; nay, even as the different Parts of the ſame *Vegetable*: That one ſhould carry a reſinous, another a milky, a third a yellow, a fourth a red Juice in its Veins; that one affords a fragrant, another an offenſive Smell; one ſweet to the Taſte, another acid, bitter, acerb, auſtere, *&c.* that one ſhould be nouriſhing, another poiſonous; one purging, another aſtringent.

And this Argument makes equally ſtrong againſt thoſe who ſuppoſe mere Water the Matter out of which all Matters are formed.

A *Cataputia* in one of the Glaſſes afforded but a little Increaſe, only 3 ½ Grains all the While, tho' 2501 Grains of Water were ſpent upon it: But this might poſſibly be owing not to the Water's wanting Matter fit for the Nouriſhment of that particular Plant, but from its being an improper *Medium* for that to grow in. Too much of that Liquor in ſome Plants may, probably, hurry the terreſtrial Matter through the Veſſels too faſt for them to lay hold of it.

But a farther Proof of this Matter is, that the Soil once proper for the Production of ſome Sort of *Vegetables*, does not ever continue ſo, but in Tract of Time loſes its Property; and ſooner in ſome Lands, and later in others.

As for Example: If *Wheat* be ſown upon Land proper for that Grain, the firſt Crop will ſucceed very well, and perhaps the ſecond and third, as long as the Ground is in Heart, as the Farmers call it; but in a few Years it will produce no more, if ſow'd with that Corn; ſome other Grain it may, as *Barley*: And after this has been ſown ſo oft, that the Land can bring no more of it, it may afterwards yield ſome good *Oats*, and perhaps *Peas* after them.

At length it becomes barren, the *vegetative* Matter that at firſt it abounded with, being reduced by the ſucceſſive Crops, and moſt of it borne off, each Sort of Grain takes out that peculiar Matter that is proper for its own Nouriſhment.

It may be brought to bear another Series of the ſame *Vegetables*; but not till it is ſupply'd with another Fund of Matter of the like Sort with what it firſt contained, either by the Ground's lying fallow for ſome Time, till the Rain hath poured a freſh Stock upon it, or by the manuring it.

That this Supply is of the like Sort, is evident by the ſeveral Manures found beſt to promote the *Vegetation*; which are chiefly either of Parts of *Vegetables*, or of Animals; which either derive their own Nouriſhment immediately from *vegetable* Bodies, or from other Animals that do ſo; in particular, the Blood, Excrements and Urine of Animals that do ſo; ſhaving of Horns and Hoofs, Hair, Feathers, calcin'd Shells, Lees of Wine and Beer, Aſhes of all Sorts of *vegetable* Bodies, Leaves, Straw, Roots and Stubble, turn'd into Earth by ploughing, or otherwiſe, to rot and diſſolve there.

Theſe are our beſt Manures, and being *vegetable* Subſtances, when refunded back again into the Earth, ſerve for the Formation of other Bodies.

But to apply this to Gardens, where the Trees, Shrubs and Herbs, after their having continued in one Station, till they have derived thence the greateſt Part of the Matter fit for their Increaſe, will decay and degenerate, unleſs either freſh Earth, or ſome fit Manure be apply'd to them.

It is true, they may maintain themſelves there for ſome Time, by ſending forth Roots farther and farther, to an Extent all around, to fetch in more Proviſion; but at laſt they muſt have a freſh Supply brought to them, or they themſelves removed or tranſplanted to ſome Place better furniſhed with Matter for their Subſiſtence. And accordingly Gardeners obſerve, that Plants that have ſtood a long while in a Place, have longer Roots than uſual, Part of which they cut off when they tranſplant to a freſh Soil, as not now of any farther Uſe to them.

All theſe Inſtances argue a particular terreſtrial Matter, and not Water, for the Subject to which Plants owe their Increaſe: Were it Water only, there would be no need of Manures, or Tranſplanting; the Rain falls in all Places, in this Field and in that, indifferently, on one Side of an Orchard or Garden as well as the other; nor could there be any Reaſon why a Tract of Land ſhould yield *Wheat* one Year and not the next, ſince the Rain ſhowers down all alike upon the Earth.

V. *Vegetables are not form'd of Water, but of a certain peculiar terreſtrial Matter.*

It has been ſhewn, that there is a conſiderable Quantity of this Matter contained both in Spring, Rain, and River-water, and the Experiments before-mentioned ſhew, that the much greateſt Part of the fluid Maſs, that aſcends up into Plants, does not ſettle or abide there, but paſſes through the Pores of them, and exhales into the Atmoſphere, and that a great Part of the terreſtrial Matter, mixed with the Water, paſſes up into the Plant along with it, and that the Plant is more or leſs augmented, in Proportion as the Water contains a greater or leſſer Quantity of Matter: From all which we may reaſonably infer, that Earth, and not Water, is the Matter which conſtitutes *Vegetables*.

One of the Sprigs of Mint before-mentioned drew up into it 2501 Grains of the fluid Maſs, and yet had received but 3½ Grains Increaſe from it.

A ſecond, tho' it had at firſt the Diſadvantage to be much leſs than a third, yet being ſet in Water, wherein Earth had been plentifully mix'd, and the other in Water without any ſuch Earth, it had vaſtly out-grown it, weighing at leaſt 145 Grains more than that did.

A fourth Plant, tho' at firſt a great deal leſs than the fifth, yet being ſet in foul, craſs Water, that was left in the Still, after that in which the laſt was ſet was drawn off, had gained in Weight, at the End, above double what that in the finer and thinner Water had.

The Proportion of the Augment of that Plant, which throve moſt, was in the ſaid Maſs ſpent upon it, but as 1 to 46, in others as one to 60, 100, 200, and in the *Cataputia*, but as 1 to 714.

One of the Sprigs took up 39 Grains of Water a Day, one Day with another, which was much more than the whole Weight of the Plant originally, and yet it gained not ¼ of a Grain a Day in Weight.

And another took up 253 Grains a Day, which was near twice as much as its original Weight, and after all, the daily Increaſe of the Plant was no more than $2\frac{1}{3}{}^{5}$ Grains.

VI. *Spring and Rain-water contain near an equal Charge of* vegetable *Matter; River-water more than either of them.*

Theſe Proportions hold in the main; but a ſtrict and juſt Compoſition is hardly to be expected; inſomuch as, in all Probability, the Water which falls in Rain contains ſometimes a greater Share of terreſtrial Matter, than that which falls at other times; a more powerful and intenſe Heat, of Neceſſity, hurrying up a larger Quantity of that Matter, along with the humid Vapours that form Rain, than one more feeble and remiſs poſſibly can.

The Water of one Spring may flow forth with an higher Charge of this Matter than that of another: This depending partly upon the Quickneſs of the Ebullition of the Water, and partly on the Quantity of that Matter latent in the *Strata*, thro' which the Fluid paſſes, and the greater or leſs Laxity of thoſe *Strata*: For the ſame Reaſon the Water of one River may abound with it more than that of another; nay, the ſame River, when much agitated and in Commotion, muſt bear up more of it than when it moves with leſs Rapidity and Violence. That there is a great Quantity of this Matter in Rivers; and that it contributes vaſtly to the ordinary Fertility of the Earth, the *Nile* affords a pregnant Inſtance, and ſo does the *Ganges* and other Rivers, which annually overflowing the neighbouring Plains, their Banks ſhew the faireſt and largeſt Crops of any in the World.

VII. *Water ſerves only for a Vehicle to the terreſtrial Matter which forms* Vegetables, *and does not itſelf make any Augmentation to them.*

Where the proper terreſtrial Matter is wanting, the Plant is not augmented, tho' never ſo much Water aſcend into it: Water then is not the Matter that compoſes *vegetable* Bodies, it is only the Agent that conveys the Matter into them, that diſtributes it to their ſeveral Parts to their Nouriſhment; that Matter is ſluggiſh and unactive, and would lie eternally confined to its Beds of Earth, without advancing up into Plants, did not Water, or ſome like Inſtrument, fetch it forth, and carry it into them.

This Fluid is capacitated ſeveral Ways for the Office here aſſigned it, by the Figure of its Parts, which appears from many Experiments to be exactly and mathematically ſpherical, their Surfaces being perfectly polite, and without any the leaſt Irregularities.

It is evident, that Corpuſcles of ſuch a Figure are eaſily ſuſceptible of Motion, and far above any others whatever, and conſequently more capable of moving and conveying other Matter that is not ſo active; then the Intervals of the Bodies of that Figure are, in reſpect to their Bulk, of all others the largeſt, and ſo the moſt fitted to receive and entertain foreign Matter in them: Beſides, as far as the Trials hitherto made inform us, the conſtituent Corpuſcles of Water are each ſingly conſidered abſolutely ſolid, and do not yield to the greateſt external Force: This ſecures their Figure againſt any Alteration, and the Intervals of their Corpuſcles muſt be always alike.

By the latter, it will ever be diſpoſed to receive Matter into it; and by the former, when once received, to bear it along with it. Water is farther capacitated to be a Vehicle to this Matter, by the Tenuity and Fineneſs of the Corpuſcles of which it conſiſts. We hardly know any Fluid in all Nature, except Fire, whoſe conſtituent Parts are ſo exceeding ſubtil and ſmall as thoſe of Water are; they will paſs Pores and Interſtices, that neither Air nor any other Fluid will. This enables them to enter the Tubes, and fineſt Veſſels of Plants, and to introduce the terreſtrial Matter, and convey it to all Part of them, whilſt each, by means of Organs it is endued with for that Purpoſe, intercepts and aſſumes into itſelf ſuch Particles as are ſuitable to its own Nature, letting the reſt paſs on through the common Ducts.

VIII. *Water is not capable of performing this Office to Plants, unleſs aſſiſted by a due Quantity of Heat.*

Heat muſt concur, or *Vegetation* will not ſucceed. The Plants ſet in the Glaſſes in *October*, and the following Months, had not near the Quantity of Water ſent up into them, or ſo great an additional Increaſe by much, as thoſe that were ſet in *June*, *July*, or the hotter Months.

It is plain the Water has no Power of moving itſelf, or riſing to the vaſt Height it doth in the more tall and lofty Plants; ſo far from it, that it doth not appear, by any Diſcovery yet made, that even its own Fluidity conſiſts in the inteſtine Motion of its Parts, whatever the *Carteſians* think.

Indeed we want nothing more to ſolve all the Phænomena of Fluidity, that ſuch a Figure and Diſpoſition of Parts as Water has; ſpherical Corpuſcles muſt ſtand ſo tickliſh upon each other, as to be ſuſceptible of every Impreſſion, and though not perpetually in Motion, muſt be always ready and liable to be put into it by any the ſlighteſt Force imaginable: 'Tis true, the Parts of Fire or Heat are not capable of moving themſelves any more than thoſe of Water; but they are more ſubtil, light, and active than thoſe are, and ſo the more eaſily put in Motion.

That the Concourſe of Heat is really neceſſary in this Work, appears not only from the Experiments before us, but from all Nature; from the Fields and Forreſts, Gardens and Orchards: We ſee in *Autumn*, as the Sun's Power is gradually leſs and leſs, ſo its Effects on Plants is remitted, and *Vegetation* ſlackens by little and little.

Its Failure is firſt diſcernable in Trees; which being raiſed higheſt above the Earth, require a more intenſe Heat to elevate the Water charged with Nouriſhment to their Tops; ſo that for want of freſh Support and Nutriment, they ſhed their Leaves, unleſs ſupported by a very firm and hard Conſtitution indeed, as our *Ever-greens* are. Next, the Shrubs part with theirs; then the Herbs and lower Tribes: The Heat at length not being ſufficient to ſupply even to theſe, tho' ſo near the Earth, the Fund of their Nouriſhment.

As the Heat returns the ſucceeding *Spring*, they all recruit again, and are furniſhed with freſh Supplies and Verdure: But firſt, thoſe which are loweſt and neareſt the Earth, and that require a leſſer Degree of Heat to raiſe the Water with its earthy Charge into them: Then the Shrubs and higher *Vegetables* in their Turn; and laſtly, the Trees.

As the Heat increaſes, it grows too powerful, and hurries the Matter with too great Rapidity through the finer and more tender Plants: Theſe therefore go off and decay; and others that are more hardy and vigorous, and require a greater Degree of Heat, ſucceed in their Order. By which Mechaniſm, provident Nature furniſhes us with a very various and different Entertainment, and what is beſt ſuited to each Seaſon all the Year round.

As the Heat of the ſeveral Seaſons affords us a different Face of Things, ſo the ſeveral diſtant Climates ſhew the different Scenes of Nature and Productions of the Earth.

The hotter Countries ordinarily yield the largeſt and talleſt Trees, and thoſe too in a much greater Variety than the colder: Even thoſe Plants common to both, attain to a much greater Bulk in the Southern, than in the Northern Climates.

Nay, there are ſome Regions ſo cold, that they raiſe no *Vegetables* at all to a conſiderable Size: This we learn from *Greenland*, *Iceland*, and other Parts of like cold Situation and Condition: in theſe there are no Trees, and the Shrubs are poor, little, and low.

Again, in the warmer Climates, and ſuch as do furniſh Trees, and the large *Vegetables*, if there happen a Remiſſion or a Diminution of the uſual Heat, their Productions are impeded in Proportion. Our cold *Summers* give us Proof enough of this; for tho' at ſuch times there is Heat ſufficient to raiſe the *vegetative* Matter into the lower Plants, as *Wheat*, *Barley*, *Peas*, and the like; and we have Plenty of *Strawberries*, *Raſpberries*, *Gooſeberries*, *Currants*, and the Fruits of ſuch *Vegetables* as are low and near the Earth; and a moderate Store of *Mulberries*, *Cherries*, *Plums*, &c. and ſome others, that grow at ſomething of a greater Height: Yet our *Apples*, *Pears*, *Walnuts*, and the Production of the taller Trees, have been fewer, and thoſe not ſo throughly ripened and brought to Perfection, as they are in more benign and warm Seaſons.

And indeed, in Trees of the ſame Kind, thoſe that keep cloſeſt to the Earth, always produce moſt and beſt Fruit: For which Reaſon it is, that Gardeners check and reſtrain the Growth of their better Fruit-Trees, and prevent their running up to too great an Height.

As to our *Grapes*, *Apricocks*, *Peaches*, *Nectarines*, and *Figs*, they being tranſplanted hither out of warmer Countries, it is leſs to be wondered at, that we fail of them in cold *Summers*.

Nor is it that Heat only which promotes *Vegetation*, but any other indifferently, according to its Power and Degree; as we find from our Stoves, Hot-beds, &c.

VERATRUM; [ſo called as though *vere atrum*, i. e. *truly black*, becauſe this Plant has a black Root, or becauſe it purges a black Humour] White Hellebore.

The *Characters* are;

The Flower is naked, conſiſting of ſix Leaves, which expand in form of a Roſe, in the Middle of which ariſes the Pointal, ſurrounded by ſix Stamina, or Threads, which afterwards turn to a Fruit, in which, for the moſt part, three membranaceous Sheaths are gathered into a little Head, and are full of oblong Seeds, reſembling a Grain of Wheat, and encompaſs'd, as it were, by a leafy Wing.

The *Species* are;

1. VERATRUM *flore ſubviridi. Tourn.* White Hellebore, with a greeniſh Flower.
2. VERATRUM *flore atro-rubente. Tourn.* White Hellebore, with a dark-red Flower.

The firſt of theſe Plants is that which is ordered for Medicinal Uſe, and is by much the ſtronger and more acrid Plant; for when both Sorts are placed near each other, the Snails will intirely devour the Leaves of the ſecond Sort, when at the ſame time they will ſcarcely touch thoſe of the firſt. The ſecond Sort doth alſo appear ſooner in the *Spring*, and flowers near a Month before the firſt Sort.

Theſe Plants are very pretty Ornaments, when planted in the Middle of open Borders of the Pleaſure-Garden; for if they are placed near Hedges or Walls, where generally Snails do harbour, they will greatly deface the Leaves, eſpecially of the ſecond Sort, by eating them full of Holes; and as a great Part of the Beauty of theſe Plants conſiſts in their broad-folded Leaves, ſo when they are thus defaced, the Pleaſure is almoſt loſt.

They may be propagated by parting their Roots toward the latter End of *February*, or the Beginning of *March*, juſt before they begin to ſhoot, and ſhould be planted in a light, freſh, rich Soil, in which they will thrive exceedingly, and produce ſtrong Spikes of Flowers. Theſe Roots ſhould not be removed oftener than once in three Years, by which Time (if they like the Soil) they will be very ſtrong, and afford many Heads to be taken off; but if they are frequently tranſplanted, it will prevent their increaſing, and cauſe them to flower very weak.

You may alſo propagate theſe Plants by Seeds, which ſhould be ſown as ſoon as ripe, either in a Bed or Box filled with freſh, light Earth, and the Ground kept conſtantly clear from Weeds. In the *Spring* the Plants will appear, at which Time, if the Seaſon be dry, you ſhould now and then refreſh them with Water, which will greatly promote their Growth; and you muſt carefully clear them from Weeds, which, if permitted to grow, will ſoon over-ſpread and deſtroy theſe Plants while young. The *Spring* following, juſt before the Plants begin to ſhoot, you ſhould prepare a Bed of freſh, light Earth, and carefully take up the young Plants, (obſerving not to break their Roots) and plant them therein about ſix Inches ſquare, where they may remain until they are ſtrong enough to flower, when they ſhould be tranſplanted into the Borders of the Pleaſure-Garden. But as theſe Plants ſeldom flower in leſs than four Years, from Seeds, ſo this Method of propagating them is not very much practiſed in *England*.

VERBASCUM; [ſo called, as though *Barbaſcum*, becauſe the Leaves of this Plant are bearded, rough, and hairy. It is alſo called *Candela Regia*, *Lychnitis*, becauſe its Leaves are uſed inſtead of Cotton in a Lamp; it is alſo called *Phlomos*, of φλέγω to *burn*, becauſe it ſeems, as it were, to burn] Mullein.

The *Characters* are;

The flower conſiſts of one Leaf, which expands in a circular Form, and is cut into ſeveral Segments; out of the Center ariſes the Pointal, which afterwards becomes an oval, pointed Fruit, divided into two Cells, by a middle Partition, which are filled with ſmall angular Seeds.

The *Species* are;

1. VERBASCUM *mas latifolium luteum. C. B. P.* Great white Mullein, High-taper, *or* Cows-Lungwort.

2. VERBASCUM *pulverulentum, flore luteo parvo. J. B.* Hoary Mullein, with ſmall yellow Flowers.

3. VERBASCUM *flore albo parvo. J. B.* White flowered Mullein.

4. VERBASCUM *nigrum, flore parvo, apicibus purpureis. J. B.* Sage-leav'd black Mullein.

5. VERBASCUM *blattariæ foliis, nigrum, amplioribus foliis ac luteis, apicibus purpuraſcentibus. Hor. Bat.* Mullein with a dark Moth-Mullein Leaf, and yellow Flowers with purpliſh Apices.

6. VERBASCUM *Orientale, ſophiæ folio. T. Cor.* Eaſtern Mullein, with a Flix-weed Leaf.

7. VERBASCUM *nigrum, folio papaveris corniculati. C. B. P.* Black Mullein, with a Horn-poppy Leaf.

8. VERBASCUM *humile Alpinum villoſum, boraginis folio & flore. Tourn.* Low hairy Alpine Mullein, with a Leaf and Flower like that of *Borage*, *commonly called* Bears-ear Sanicle.

9. VERBASCUM *fœmina, flore luteo magno. C. B. P.* Female Mullein, with a large yellow Flower.

10. VERBASCUM *anguſtifolium ramoſum, flore aureo, folio craſſiore. J. B.* Branching narrow-leav'd Mullein, with a golden Flower, and a thicker Leaf.

11. VERBASCUM *foliis viridibus, annuum, floribus luteis. H. L.* Annual Mullein, with green Leaves and yellow Flowers.

12. VERBASCUM *nigrum Dioſcoridis. Lob. Icon.* Black Mullein of Dioſcorides.

13. VERBASCUM *Alpinum perenne nigrum, flore albo, ſtaminibus purpureis. H. R. Par.* Black perennial Mullein of the Alps, with a white Flower, and purple Chives.

14. VERBASCUM *ramoſum floribus albis parvis. Mor. H. R. Blæſ.* Branching Mullein, with ſmall white Flowers.

15. VERBASCUM *Creticum ſpinoſum fruteſcens. Tourn. Cor.* Shrubby and thorny Mullein of Crete.

16. VERBASCUM *Græcum fruticoſum, folio ſinuato candidiſſimo. Tourn. Cor.* Shrubby Mullein of Greece, with a very white indented Leaf.

17. VERBASCUM *orientale maximum candidiſſimum, ramis candelabrum æmulantibus. Tourn. Cor.* The greateſt and whiteſt Eaſtern Mullein, with Branches reſembling a Candleſtick.

18. VERBASCUM *orientale, conyzæ folio, flore micante, è ferrugineo ad aureum colorem vergente. Tourn. Cor.* Eaſtern Mullein, with a Flea-bane Leaf, and a ſhining Flower, from an Iron inclining to a Gold Colour.

19. VERBASCUM *orientale, betonicæ folio, flore magno. Tourn. Cor.* Eaſtern Mullein, with a Betony Leaf, and a larger Flower.

20. VERBASCUM *orientale anguſto oblongo folio. Tourn. Cor.* Eaſtern Mullein, with an oblong and narrow Leaf.

21. VERBASCUM *orientale, foliis ſubrotundis candidiſſimis. Tourn. Cor.* Eaſtern Mullein, with roundiſh white Leaves.

The four firſt Sorts grow wild in divers Parts of *England*, and are rarely cultivated, except in Botanick Gardens for Variety. The firſt Sort is that which is uſed in Medicine, which is the moſt common of them all, growing upon the Sides of dry Banks, in moſt Parts of *England*.

Theſe may be all cultivated by ſowing their Seeds in *Auguſt*, on a Bed of light Earth, in an open Situation, where the Plants will come up the ſucceeding Month, and will endure the *Winter*'s Cold very well, provided they have a dry Soil. In *February* the Plants ſhould be tranſplanted where they are to remain, allowing them a great Diſtance; for they grow pretty tall and large: In *June* following they will flower, and their Seeds will be ripe in *July*. But notwithſtanding theſe Plants grow wild in *England*, yet two or three of each Kind may be admitted in large Gardens, for the Variety of their hoary Leaves, together with the extreme Sweetneſs of their Flowers, which have a Scent ſomewhat like Violets.

The fifth, ſixth and ſeventh Sorts are not Natives of this Country, but have been obtained from abroad; the fifth was ſent from *Leyden*, by the learned Dr. *Boerhaave*, but I do not at preſent know from whence he received it. The ſixth Sort was gathered by my ingenious Friend Mr. *Henry Hopkey*, upon *Gibraltar* Hills, from whence he ſent me the Seeds, which flouriſh'd in the *Phyſick Garden* very well two Years, and flower'd extremely, but did not perfect Seeds; and being a biennial Plant, is ſince entirely decay'd.

The ſeventh Sort was found in the *Levant*, by Monſieur *Tournefort*, chief Botaniſt to the late *French* King, who brought the Seeds to the Royal Gardens at *Paris*, from whence it hath been communicated to ſeveral other curious Gardens in *England* and *Holland*. This Plant is alſo biennial, and rarely produces good Seeds in *England*, unleſs the *Summer* be warm and dry.

Theſe Sorts may be propagated in the ſame Manner as the four firſt, but ſhould be planted in a warm, dry Situation in *Winter*, otherwiſe they are very ſubject to be deſtroy'd by Froſt, being Natives of warmer Countries.

The eighth Sort is a Native of the *Alps* and *Pyrenean* Mountains, and was formerly preſerved in ſeveral Gardens with great Care, being placed in the Green-houſe in *Winter*, as ſuppoſing it too tender to endure the Cold of our Climate in the open Air; but this is now treated in a different Manner, for it ſhould be placed, as much as poſſible, in the Shade, and manag'd as *Auricula's*, with which Treatment it thrives much better than if preſerv'd with great Tenderneſs, and will produce Flowers and Seeds in great Plenty. This Plant may be propagated by Off-ſets, as is practiſed for *Auricula's*, and ſhould be planted in a light, rich Earth, in which it will multiply very faſt.

The ninth, tenth, eleventh, twelfth, thirteenth and fourteenth Sorts are very hardy Plants, which grow wild in ſeveral Parts of *Europe*, but are preſerved in the Gardens of curious Botaniſts for the ſake of Variety.

The fifteenth Sort grows in the Iſland of *Crete* in the *Archipelago*, where it riſes to the Height of three Feet, having a woody Stem; and divides into many Branches, which are armed with Thorns towards their Extremities. The Leaves are oblong, narrow, and ſinuated like thoſe of the *Wild Rocket*, but are very white and woolly. The Flowers are produced near the Extremity of the Branches, which are of a yellow Colour, reſembling thoſe of the *Wall-flower*; from whence ſome Authors have named it *Leucoium ſpinoſum*, i. e. Prickly Gilliflower.

The ſixteenth Sort is very like the ſeventh; but Dr. *Tournefort*, who found this in the *Archipelago*, thinks it to be different, becauſe it has not degenerated in the Royal Garden at *Paris*, as the other Sort commonly will do when it has been cultivated two or three Years in a Garden. This Sort ſeldom continues longer than two or three Years before the Roots periſh.

The ſeventeenth, eighteenth, nineteenth, twentieth and twentyfirſt Sorts, were diſcovered by Dr. *Tournefort* in the *Levant*, from whence he ſent their Seeds to the Royal Garden at *Paris*. All theſe Sorts are hardy enough to thrive in the open Air in *England*, provided they are ſown on a dry undunged Soil; for when they grow on a moiſt Soil, their Roots are ſubject to rot in the *Winter*; and if the Ground is enriched with Dung, it cauſes the Plants to grow ſo rank in *Autumn*, that they are in Danger of being deſtroyed by hard Froſt.

All theſe Plants are propagated by Seeds, which ſhould be ſown on a Bed of light freſh Earth, in an open Situation. The beſt Time to ſow theſe Seeds is in *Autumn*, ſoon after they are ripe; when they will more certainly grow than if they are ſown in the *Spring:* And when they are ſown early in the *Autumn*, the Plants will flower the following *Summer*, by which there will be a Year ſaved. Theſe Seeds ſhould be ſown in Drills, which ſhould be made about eighteen Inches aſunder, becauſe it will be proper to let ſome of the Plants remain to flower in the Seed-bed, where they will grow much ſtronger than thoſe which are tranſplanted; when the Plants come up, they ſhould be kept clean from Weeds; and about *Michaelmas* ſome of the Plants ſhould be carefully drawn out, where they grow too cloſe together, which may be tranſplanted out into a Nurſery-bed to get Strength; and afterward they may be removed, and planted about in Wilderneſs Quarters; where (if they are not too much over-ſhaded by Trees) they will thrive and flower very well, and make an agreeable Variety. Thoſe Plants which are left in the Seed-beds to flower, ſhould be ſingled out to a Foot or more Diſtance in the Rows; otherwiſe they will not have Room to ſpread.

There are very few of the *Mulleins* which are planted in Gardens for Ornament; becauſe ſeveral of the Sorts grow wild in *England*, for which Reaſon many Plants are rejected, and meaner Sorts are cultivated, becauſe they are more rare: But in large Gardens, where there are many Wilderneſs Quarters, theſe Plants are very proper Furniture, becauſe they require very little Care to cultivate them, and they continue a long time in Flower; and tho' they do not make ſo fine an Appearance as ſome other Plants, yet for the agreeable Scent of their Flowers, which reſemble the Violets, they deſerve a Place much better than many other Plants which are cultivated in Gardens.

The fifteenth Sort being tenderer than any of the others, ſome of the Plants ſhould be planted in Pots, filled with freſh light Earth, that they may be ſheltered under a Hot-bed Frame in *Winter*, where they ſhould have as much free Air as poſſible in mild Weather, and covered only in very hard Froſt. The other Plants may be planted on a dry Soil in a warm Situation, where they will endure the Cold of our ordinary *Winters* very well.

VERBENA; [takes its Name of *verrere*, Lat. to *bruſh*, becauſe in old Times it was uſed in cleanſing the Altars: It was alſo called *Periſterium*, of Περιστερὰ, a *Dove*, becauſe Doves are greatly delighted with it. There is no Herb of which the Ancients have ſaid ſo much of its being Vulnerary or Wound-herb; whence it is called *Herba Vulneraria*, or a Species of the *Sideritis:* There has been no Herb of which the Poets have been more fertile in their Fictions, no Herb more commended for Sacrifices; whence it is called *Hierebotane*, of ἱερὰ *ſacred*, and Βοτάνη an *Herb:* Nor any Herb of which the *Magi* have been fuller of their Fables: They ſay, that if a Perſon crop it with his Left-hand, being circumſcribed in a Circle, before he has ſeen Sun or Moon, then he ſhall obtain whatſoever he wiſhes for; but if it be plucked with the Right-hand, nothing will favour him.] Vervain.

The *Characters* are:

It hath a labiated Flower, conſiſting of one Leaf, whoſe upper Lip is upright, and commonly divided into two, but the under Lip is cut into three Parts, ſo that at the firſt Sight it appears like a Flower with five Leaves; theſe Flowers are each ſucceeded by four naked Seeds, which fill the Calyx: To which may be added, the Flowers do generally grow in Spikes or Heads, but not in Whorles round the Stalks.

The *Species* are;

1. VERBENA *communis, cæruleo flore. C. B. P.* Common Vervain, with a blue Flower.
2. VERBENA *Luſitanica latifolia procerior. Tourn.* Taller broad-leav'd Portugal Vervain.
3. VERBENA *Urticæ folio, Canadenſis. H. R. Par.* Canada Nettle-leav'd Vervain.
4. VERBENA *Americana, ſpica multiplici, foliis Urticæ anguſtioribus, floribus cæruleis. Par. Bat. Brod.* American Vervain, with many Spikes, narrow Nettle Leaves and blue Flowers.
5. VERBENA *tenuifolia. C. B. P.* Narrow-leav'd Vervain.
6. VERBENA *Urticæ folio longiore ſerrato. Houſt.* American Vervain, with a longer ſawed Nettle Leaf.
7. VERBENA *Bonarienſis altiſſima, lavendulæ Canarienſis ſpica multiplici. Hort. Elth.* The talleſt Vervain of Buenos Ayres, with many Spikes reſembling the Canary Lavendar.
8. VERBENA *Carolinienſis, meliſſæ folio aſpero. Hort. Elth.* Carolina Vervain, with a rough Balm Leaf.
9. VERBENA *Mexicana, trachelii folio, fructu aparines. Hort. Elth.* Mexican Vervain, with a Throatwort Leaf, and a Fruit like Gooſe-graſs.

The firſt Sort is very common in moſt Parts, and is rarely cultivated in Gardens; this is the Sort which is directed by the *College of Phyſicians* for medicinal Uſe, and is brought to the Markets by thoſe who gather it in the Fields.

The ſecond, third and fourth Sorts, tho' not Natives of this Country, yet are very hardy, and will endure the ſharpeſt of our *Winters* in the open Air.

Theſe may be all propagated by ſowing their Seeds on a Bed of freſh Earth in the *Spring*, and when the Plants come up, they ſhould be tranſplanted out, or thinned ſo as to allow them ten or twelve Inches Diſtance, (for they generally grow pretty large, and require to have Room) after which they will require no farther Care, but to clear them from Weeds, and the ſecond *Summer* they will flower and ſeed, which, if permitted to fall upon the Ground, will come up the ſucceeding *Spring*, without any farther Culture.

The fifth Sort is equally as hardy as the common Vervain, from which it only differs in having narrower Leaves; ſo is never admitted in Gardens, unleſs for the ſake of Variety.

The ſixth Sort was diſcover'd by the late Dr. *William Houſtoun* in *Jamaica*, from whence he ſent the Seeds into *England*. This is a biennial Plant, which commonly periſhes ſoon after it has perfected its Seeds.

The ſeventh Sort was brought from *Buenos Ayres*. This Plant grows to the Height of five or ſix Feet, or more, and produces its Flowers at the Extremity of the Branches in many ſlender Spikes, which are placed cloſe together, ſomewhat like the *Canary* Lavendar. Theſe Flowers are ſmall, and of a blue Colour.

The eighth Sort is a Native of *Carolina*. This is a much humbler Plant, for it rarely riſes above two Feet and a half high. This produces its Flowers in Spikes like the common Sort.

The ninth Sort was brought from *Mexico*. This commonly grows about three Feet high, or more, and generally produces three Spikes from a Joint at the Extremity of the Branches. The Flowers are Male and Female on the ſame Spike. The Female Flowers produce their Seeds covered with the Empalement, which ſwells into a roundiſh Form, ſo as to appear ſomewhat like the Seeds of Gooſe-graſs, or Clivers.

The ſixth, ſeventh and ninth Sorts are tender Plants, which may be propagated by Seeds, and ſhould be ſown on a Hot-bed early in the *Spring*; but when the Plants are come up, they muſt have a good Share of free Air admitted to them in warm Weather, otherwiſe they will draw up too weak: They muſt alſo be often refreſhed with Water. When the Plants have obtained ſome Strength, they ſhould be tranſplanted on another moderate Hot-bed, obſerving to ſhade them until they have taken new Root; after which Time they muſt have Air and Moiſture in warm Weather in great Plenty, which will ſtrengthen the Plants. About the Beginning of *June*, the Plants ſhould be carefully taken up with Balls of Earth to their Roots, planted into Pots fill'd with freſh light Earth, and then plunged into a very moderate Hot-bed, where they ſhould be ſcreened from the Sun until they have taken new Root; and then they ſhould be inured to the open Air by Degrees; for in *July* they may be removed out of the Hot-bed, and placed in a warm ſheltered Situation, where they may remain till the Middle or latter End of *September*, when they muſt be removed into the Stove; where, if they have a moderate Degree of Warmth in *Winter*, and are duly ſupply'd with Water, the Plants may be preſerved, and the following *Summer* they will produce Flowers; and if the Seaſon proves favourable, they will perfect their Seeds in *Autumn*.

The ſeventh Sort is much more hardy than thoſe laſt mentioned, ſo may be ſown on a Bed of light Earth in a warm Situation, about the Middle of *March*; and when the Plants are come up, they muſt be conſtantly kept clean from Weeds, until they are ſtrong enough to tranſplant; when they muſt be carefully taken up, and ſome of them planted into ſmall Pots filled with freſh light Earth, and placed in a ſhady Situation, until they have taken new Root; then they may be placed in an open Situation with other hardy exotick Plants, where they may remain during the *Summer* Seaſon; but in *Winter* they muſt be ſheltered from ſevere Froſt. The other Plants may be planted in a warm Border, where they will endure the Cold of our ordinary *Winters* without Covering; but in hard *Winters* theſe are ſometimes deſtroy'd;

for which Reaſon, it will be proper to have ſome of the Plants in Pots, in order to preſerve the Kind. This Sort flowers and produces good Seeds in this Country, but the Roots ſeldom continue above two or three Years.

VERGE, is the Edge or Outſide of a Border; but in Gardening it is generally underſtood to be a Slip of Graſs which joins to Gravel-walks, and divides them from the Borders in the Parterre Garden.

VERONICA; [was ſo called after the Princeſs *Veronica*, who firſt diſcover'd it.] Speedwell, *or* Fluellin.

The *Characters* are;

The Leaves, for the moſt part, grow oppoſite by Pairs; the Calyx conſiſts of one Leaf, which is divided into four Parts, and expands in form of a Star; the Flower conſiſts of one Leaf, which is, for the moſt part, divided into four Segments, and expands in a circular Order; when the Flower decays, the Ovary becomes a membranaceous Fruit, divided into two Cells, which are ſhaped like a Heart, and are filled with Seeds, which are ſometimes ſmall, and at other times large and thick.

The *Species* are;

1. VERONICA *mas ſupina & vulgatiſſima. C. B. P.* Common Male Speedwell, *or* Fluellin.
2. VERONICA *ſpicata anguſtifolia. C. B. P.* Narrow-leav'd ſpik'd Speedwell.
3. VERONICA *major latifolia erecta. Mor. Hiſt.* Greater broad-leav'd upright Speedwell.
4. VERONICA *multicaulis Pannonica. Tourn.* Hungarian Speedwell, bearing many Stalks or Spikes of Flowers.
5. VERONICA *ſpicata Cambro-Britannica, bugulæ ſub hirſuto folio. Raii Syn. Edit.* 3. Welſh ſpiked Speedwell, with a hairy Bugle Leaf.
6. VERONICA *cærulea, trifido aut quinquefido folio. Flor. Bat.* Blue Speedwell, with a trifid or quinquefid Leaf.
7. VERONICA *Virginiana altiſſima, ſpica multiplici, floribus candidis. Flor. Bat.* Tall Virginian Speedwell, with many Spikes, and white Flowers.
8. VERONICA *ſpicata longifolia. Tourn.* Long-leav'd ſpiked Speedwell.
9. VERONICA *petræa ſemper-virens, Pon. Bald.* Evergreen Rock Speedwell.
10. VERONICA *mas repens Pyrenaica, folio longiori glabro. Schol. Bot.* Male creeping Pyrenean Speedwell, with a longer ſmooth Leaf.
11. VERONICA *mas erecta. C. B. P.* Male upright Speedwell.
12. VERONICA *ſpicata, flore purpureo. Mor. Hort. Reg. Blæſ.* Spiked Speedwell, with a purple Flower.
13. VERONICA *ſpicata minor. C. B. P.* Smaller ſpiked Speedwell.
14. VERONICA *Alpina fruteſcens. C. B. P.* Shrubby Speedwell of the Alps.
15. VERONICA *Alpina fruticans, ſerpilli minoris folio circinato. Pluk. Phyt.* Shrubby Speedwell of the Alps, with a round leſſer Mother-of-thyme Leaf.
16. VERONICA *fruteſcens durior, oblongo chamædryos folio, Patavina. Bocc. Muſ.* Harder ſhrubby Speedwell of Padua, with an oblong Germander Leaf.
17. VERONICA *Auſtriaca foliis tenuiſſimè laciniatis. Inſt. R. H.* Auſtrian Speedwell, with Leaves finely jagged.
18. VERONICA *maxima. Lugd.* The greateſt Speedwell, or Falſe Germander.
19. VERONICA *maxima Pyrenaica, non ramoſa. Inſt. R. H.* The greateſt unbranched Speedwell, of the Pyrenean Mountains.
20. VERONICA *major fruteſcens altera. Mor. Hiſt.* Another greater ſhrubby Speedwell, *or* Falſe Germander.
21. VERONICA *ſupina, facie teucrii pratenſis. Lob. Icon.* Low Speedwell, with the Face of Meadow-germander.
22. VERONICA *longifolia Virginiana altiſſima, foliis ternis profunde ſerratis caulem amplexantibus, ſpicâ multiplici cæruleâ. Royen.* The talleſt long-leav'd Virginian Speedwell, with deeply-ſawed Leaves embracing the Stalks, and many Spikes of blue Flowers.
23. VERONICA *minor anguſtifolia ramoſior & procumbens. Mor. Hiſt. Oxon.* Small narrow-leav'd branching and trailing Speedwell.
24. VERONICA *aquatica major, folio ſubrotundo. Mor. Hiſt.* Greater Water Speedwell, with a roundiſh Leaf, *commonly called* Brook-lime.
25. VERONICA *aquatica, anguſtiore folio. Inſt. R. H.* Narrow-leav'd Water Speedwell, *or* Brooklime.
26. VERONICA *aquatica minor, folio ſubrotundo. Inſt. R. H.* Leſſer Water Speedwell, with a roundiſh Leaf.
27. VERONICA *aquatica major, folio oblongo. Mor. Hiſt.* Greater Water Speedwell, *or* Brooklime, with an oblong Leaf.
28. VERONICA *aquatica minor, folio oblongo. Mor. Hiſt.* Small Water Speedwell, with an oblong Leaf.
29. VERONICA *Conſtantinopolitana incana, chamædryos folio. Tourn. Cor.* Hoary Speedwell of Conſtantinople, with a Germander Leaf.
30. VERONICA *orientalis, foliis hederæ terreſtris flore magno. Tourn. Cor.* Eaſtern Speedwell, with Ground-ivy Leaves, and a large Flower.
31. VERONICA *orientalis erecta, gentianellæ foliis. Tourn. Cor.* Upright Eaſtern Speedwell, with ſmall Gentian Leaves.
32. VERONICA *orientalis elatior, gentianellæ foliis, flore majore albido. Tourn.* Taller Eaſtern Speedwell, with ſmall Gentian Leaves, and a larger white Flower.
33. VERONICA *orientalis minima, foliis laciniatis. Tourn. Cor.* The leaſt Eaſtern Speedwell, with jagged Leaves.
34. VERONICA *orientalis, telephii folio. Tourn. Cor.* Eaſtern Speedwell, with an Orpine Leaf.
35. VERONICA *major fruteſcens altera, foliis conſtanter & eleganter variegatis. Boerh. Ind. alt.* The other great ſhrubby Speedwell, with Leaves conſtantly and beautifully variegated.
36. VERONICA *Americana erecta, foliis gramineis, floribus ex foliorum alis. Houſt.* Upright American Speedwell, with Graſs Leaves, and Flowers coming out of the Wings of the Leaves.
37. VERONICA *fruticoſa erecta dulcis, hexangulari caule, flore dilute cæruleo. Sloan. Cat.* Wild Liquoriſh, *or* Sweet-weed.
38. VERONICA *caule hexangulari, foliis ſatureiæ ternis ſerratis. Sloan. Cat.* Speedwell, with an hexangular Stalk, and ſawed Savory Leaves growing by Threes.
39. VERONICA *quæ ſcordium maritimum, fruticoſum procumbens flore cæruleo. Sloan. Cat. Houſt.* Shrubby trailing maritime Speedwell, *or* Scordium, with a blue Flower.

The firſt Sort grows wild in Woods and other ſhady Places in divers Parts of *England*, and is a Plant of little Beauty, but as it is the Sort which is uſed in Medicine, under the Title of *Paul's Betony*, ſo I thought it not amiſs to ſet it down here. This is generally brought to Market by ſuch Perſons who make it their Buſineſs to gather Herbs in the Fields to ſupply the ſame, ſo that it is not often cultivated in Gardens; but thoſe who have a mind to propagate it, may do it with much Eaſe; for as the Branches trail upon the Ground, they puſh out Roots from their Joints, which Branches being cut off, and planted, will take Root and grow in almoſt any Soil or Situation.

The ſecond, third, and fourth Sorts are very ornamental Plants in the large borders of the Flower-Garden, particularly the fourth which produces a great Number of Spikes of beautiful blue Flowers. Theſe continue flowering at leaſt two Months, and in cool, moiſt Seaſons much longer; and theſe Flowers are very proper to cut for Baſons or Flower-pots to adorn Rooms in the *Summer*-ſeaſon.

The fifth Sort is a Native of the Mountains in *Wales*, from whence it hath been tranſplanted into many curious Gardens. This produces fine large Spikes of blue Flowers, and deſerves a Place in every Garden.

The ſixth, ſeventh, eighth, and ninth Sorts are Natives of warmer Countries than *England*, but are hardy enough to endure the Cold of our *Winters* very well, provided they are planted in a dry Soil. Theſe are all pretty Varieties, and do ſucceed each other in Flowering, which renders them worthy of a Place in every curious Garden. Theſe ſhould all be planted in the Middle of the Borders in the Pleaſure-Garden, (except the fifth and ninth, which ſeldom grow above a Foot high, and ſo are better placed amongſt Flowers of the ſame Growth) where, being intermix'd with other Flowers, they afford an agreeable Variety.

They may be propagated by parting of their Roots, which commonly increaſe very faſt, ſo that the raiſing them from Seeds is ſeldom practiſed. The beſt Time for parting and tranſplanting the Roots is in *September*, that they may have Time to take freſh Root before the *Winter* comes on; and theſe being fix'd in *Autumn*, will be much ſtronger than thoſe which are removed in the *Spring*, and will produce a greater Number of Flowers.

They may be planted in almoſt any Situation, but ſhould have a middling freſh Soil, not too wet, in which they will thrive exceedingly, and require no farther Care but to keep them clear from Weeds, and to part their Roots every *Autumn*; for if they are ſuffered to remain too long unremoved, their Roots will ſpread, and take up too much Room in the Borders, ſo as to injure ſuch Plants as grow near them.

The tenth and thirteen following Sorts are very hardy abiding Plants, and may be propagated either by Seeds, or parting of their Roots. If propagated by Seeds, they ſhould be ſown on an open Bed of freſh Earth in *March*, and in *April* the Plants will come up, when they muſt be kept clear from Weeds; and if the Seaſon ſhould prove very dry, if they are watered two or three times a Week, it will cauſe them to make a great Progreſs. Where the Plants come up too cloſe together, ſome of them ſhould be drawn up, and tranſplanted into Nurſery-beds, where they ſhould be ſhaded and watered until they have taken new Root; and then they will require no farther Care, but to keep them clean from Weeds until *Michaelmas*, when they will be fit to tranſplant out where they are deſigned to remain for good. All theſe Sorts are very proper to plant on the Side of ſloping Banks, or in wilderneſs Quarters under Trees, where they will flower a long time, and make an agreeable Variety.

The twenty-ſecond Sort is a Plant of larger Growth than the others: this commonly riſes four or five Feet high, if it is planted on a good Soil; and produces fine Spikes of blue Flowers, which in a cool Seaſon, or when they grow on a moiſt Soil, and in a ſhady Situation, will continue in Beauty a long time; for which it may deſerve a Place in every good Garden.

Theſe Plants may alſo be propagated by parting of their Roots, which may be done every third Year; for if they are too often parted, or divided into ſmall Heads, they will not make any Figure, becauſe when they have not a Number of Stems, ſo as to form a good Bunch, they are ſoon paſt their Beauty, and have but a mean Appearance. The beſt Time to part theſe Roots is at *Michaelmas*, that they may be well rooted again before *Winter*; for when they are removed in the *Spring*, they ſeldom flower ſtrong the ſame Year, eſpecially if the Seaſon ſhould prove dry. Thoſe Sorts which grow pretty tall, are very proper to plant under large Trees, in open wilderneſs Quarters; but thoſe trailing Branches are fit for the Sides of Banks, or irregular ſhady Slopes, where they will make an agreeable Variety.

The twenty-fourth Sort is uſed in Medicine, being accounted a very good Antiſcorbutic; it is ſtiled *Becabunga* in the Diſpenſatory, and in *Engliſh Brooklime*. It is very common in ſtanding Waters, in moſt Parts of *England*, ſo is ſeldom admitted into Gardens.

The twenty-fifth, twenty-ſixth, twenty-ſeventh and twenty-eighth Sorts, grow in ſtanding Waters, ſo are only preſerved in ſome Botanic Gardens for the ſake of Variety. Theſe may be eaſily propagated by taking the Plants from the Places of their natural Growth, and putting them on the Surface of ſhallow ſtanding Waters, where they will ſoon ſtrike out their Roots, and multiply exceedingly.

The ſix Sorts next mentioned were diſcovered by Dr. *Tournefort* in the *Levant*, from whence he ſent their Seeds to the Royal Garden at *Paris*: theſe are all of them hardy Plants, ſo will thrive in the open Air. They may be propagated by Seeds in the ſame manner as the above-mentioned, and deſerve a Place in good Gardens for their Variety.

The thirty-fifth Sort is preſerved in Gardens for the ſake of its beautiful variegated Leaves, which make a pretty Appearance in the *Winter*. This may be propagated by parting of the Roots, or from Slips taken off in the *Spring*, and planted in a ſhady Border, which if duly watered, will take Root; and the *Michaelmas* following they may be tranſplanted where they are deſigned to remain.

The thirty-ſixth Sort was diſcovered by the late Dr. *Houſtoun* at *La Vera Cruz*, from whence he ſent the Seeds to *England*. This is a low annual Plant, which ſeldom riſes above four or five Inches high. The Flowers are produced from the Wings of the Leaves, and are very ſmall and white. This grows on ſandy Ground, where the Seeds ſcatter, and the Plants come up in plenty.

The thirty-ſeventh, thirty-eighth and thirty-ninth Sorts, grow plentifully in the Iſland of *Jamaica*, from whence they have been brought into *Europe*, and are preſerved in ſeveral curious Botanic Gardens, for the ſake of Variety. All theſe being Plants natural to hot Countries, are too tender to thrive in the open Air in *England*: ſo their Seeds ſhould be ſown on a Hot-bed early in the *Spring*; and when come up, each Plant ſhould be tranſplanted into a ſeparate ſmall Pot, and plunged into a moderate Hot-bed of Tanners-bark, obſerving to ſhade them until they have taken new Root; and then they may be treated in the ſame manner as is directed for the *Samoloides*, with which Management they will flower, and perfect their Seeds in *England*.

I cannot omit mentioning the Virtues of the common Speedwell, which have cauſed it to be in great Requeſt of late. It is found an excellent Remedy for the *Gout*, and all Rheumatic Diſorders. The Method is to make a Tea of the dried Herb, the Quantity to be uſed is about a quarter of an Ounce, from which four common Diſhes of Tea may be drawn: theſe are to be drank every Morning, until the Patient finds Relief. To this ſome add the dried Herbs of *Bog-bean* and *Ground-pine*, which they mix in equal Quantities, and make a Tea of them, from which many Perſons have received great Benefit.

VIBURNUM; The Way-faring *or* Pliant Mealy Tree.

The *Characters* are;

The Flower conſiſts of one Leaf, which is divided into five Parts, and expands in a circular Order; theſe are collected into the Form of an Umbrella; the Ovary, which is placed on the upper part of the Flower, becomes a ſoft Berry, full of Juice, which contains one ſtony, compreſs'd, furrow'd Seed.

The *Species* are;

1. VIBURNUM. *Matth.* The common Viburnum, *or* Pliant Mealy Tree.
2. VIBURNUM *folio variegato.* The common Viburnum, with ſtrip'd Leaves.
3. VIBURNUM *Americanum odoratum, urticæ foliis latioribus, ſpinoſum, floribus miniatis. Par. Bat. Prod.* American ſweet-ſcented Viburnum, with broad Nettle Leaves, beſet with Thorns and Vermilion Flowers.
4. VIBURNUM *Americanum odoratum, foliis urticæ, floribus miniatis. H. L.* American ſweet-ſcented Viburnum, with Nettle Leaves, and Vermilion Flowers.
5. VIBURNUM *ciſti fœminæ ſive ſalviæ foliis mucronatis, Americanum odoratum minus, floribus incarnatis. Par. Bat. Prod.* Leſſer American Viburnum, with Leaves like the Female Ciſtus, and pale-colour'd Flowers.
6. VIBURNUM *Americanum, ſalviæ foliis obtuſis, floribus albis. Par. Bat. Prod.* American Viburnum, with blunt Sage Leaves, and white Flowers.
7. VIBURNUM *Americanum, ciſti fœminæ ſeu ſalviæ foliis mucronatis, floribus luteis. Par. Bat. Prod.* American Viburnum, with Leaves like thoſe of the Female Ciſtus, and yellow Flowers.
8. VIBURNUM *Americanum, folio urticæ, floribus ex aureo & roſeo miſtis. Boerh. Ind.* American Viburnum, with a Nettle Leaf, and gold and roſe-coloured Flowers intermixed.
9. VIBURNUM *Carolinianum, floribus purpuraſcentibus ex alis foliorum.* Carolina Way-faring-tree, with purpliſh Flowers, coming out from the Wings of the Leaves.
10. VIBURNUM *Americanum latifolium, floribus albis, ramulis tomentoſis.* Broad-leav'd American Way-faring-tree, with white Flowers, and woolly Branches.

The firſt of theſe Trees is very common in divers Parts of *England*, particularly in *Kent*, where it grows in moſt of the Hedges upon the dry, chalky Hills, near *Graveſend*, *Rocheſter*, &c. in very great Plenty. But notwithſtanding its being thus common, yet it deſerves a Place in ſmall Wilderneſs Quarters, among other flowering Trees, where, by its mealy Leaves and Shoots, together with its large Bunches of white Flowers in the *Spring*, which are ſucceeded by red Berries in *Autumn*, it affords an agreeable Variety.

This Tree may be propagated either from Seeds, or by laying down the tender Branches; but the former Method being tedious, is ſeldom practiſed, eſpecially ſince young Plants may be taken from the Woods or Hedges, where there are many of the old Trees growing; from which a Number may ſoon be propagated.

The beſt Time for laying theſe Branches is in *Autumn*, juſt as the Leaves begin to fall, (the Manner of laying them being the ſame as for other hardy Trees, need not be here repeated;) by the ſucceeding *Autumn* the Layers will be rooted, when you may take them off from the old Plants, and tranſplant them into a Nurſery for two or three Years, in which they may be trained up to regular Stems and Heads, and may afterwards be planted where they are to remain. This Tree commonly grows about twelve or fourteen Feet high, but it is rarely ſeen above ſixteen or eighteen, ſo that it ſhould be planted in Lines with ſuch Trees as do not exceed this Growth; otherwiſe it will be hid thereby, and their Beauty loſt.

The ſtrip'd Sort may be propagated by inarching it upon the plain Sort. This is preſerv'd by ſuch as delight in variegated Plants, but there is no great Beauty in it; but theſe Trees do ſeldom grow near ſo large as thoſe of the plain Sort, as is the Caſe of all other ſtrip'd Plants.

There is alſo another Sort very like to the common, which has been introduc'd into the *Engliſh* Gardens lately, which was brought from *Virginia*; but as this Sort has not yet flowered with us, ſo I can't ſay how it differs from ours. This was at firſt ſomewhat tender, while young, and in the ſharp *Winter*, *Anno* 1728. the Plants of this Kind, which were placed in the open Air, were kill'd down to the Ground; but the Roots of moſt of them ſhot up again the ſucceeding *Spring*, and have ſince endured the Cold of our *Winters* very well.

All the other *American* Sorts are Natives of the warm Parts of the *Weſt-Indies*, where, by the *Engliſh* Inhabitants, they are promiſcuouſly called *Wild Sage*; but by the Natives of thoſe Countries, they are called *Camara*, which, by *Pere Plumier*, is the Name appropriated to the Genus.

Theſe are all tender Plants, requiring the Aſſiſtance of a Stove, to maintain them in this Country. They may be propagated by planting their Cuttings, during any of the *Summer* Months, into Pots fill'd with freſh, light, rich Earth, and plunged into a moderate Hot-bed, obſerving to water and ſhade them until they have taken Root, after which they may be removed into the Stove, hardening them by degrees to bear the open Air, into which they ſhould be remov'd in *July*, placing them where they may be defended from ſtrong Winds, in which Situation they may remain until the Middle or latter End of *September*, when they muſt be carried into the Stove, and placed where they may have a moderate Warmth, but as much free Air as poſſible in very mild Weather.

During the *Winter* Seaſon theſe Plants muſt be frequently refreſhed with Water, which ſhould be placed in the Stove at leaſt twenty four Hours before it be uſed, that it may have acquired a proportionable Warmth to the Air of the Houſe, and muſt be given to them in ſmall Quantities; for much Wet at that Seaſon is very injurious to theſe Plants. The temperate Heat (as mark'd on Mr. *Fowler*'s Botanical Thermometers) is what theſe Plants ſucceed beſt with; for if the Stove be kept too warm, the Plants are very ſubject to ſhoot in *Winter*, and the Branches which are produc'd at that Seaſon are always weak, and ſeldom flower well, ſo that the Strength of the Plant is greatly exhauſted in nouriſhing weak and irregular Shoots: But if the Houſe in which they are plac'd be not kept too near that Heat, the tender Shoots will decay, and many times the Heads of the Plants will be intirely deſtroy'd by Cold.

In *June*, when the Weather is ſettled, theſe Plants may be brought out of the Houſe, but they ſhould not be expos'd to the open Air and Sun at firſt, but rather placed near Hedges or other Trees, whereby they may be ſhelter'd, and by degrees inured to the open Air; which if they are ſuddenly expos'd to, will cauſe their Leaves to change brown, and appear unſightly; and the Growth of the Plants will alſo be greatly retarded thereby. During the Time they are abroad, they muſt be frequently watered; for the Sun and Air will dry the Earth in the Pots, much faſter than while they remain'd in the Houſe; ſo that if they are not ſupply'd with Moiſture, they will not produce their Flowers ſo ſoon, nor near ſo ſtrong, in which the Beauty of theſe Plants doth conſiſt.

The Beginning of *Auguſt* the Flowers will begin to appear at the Extremity of the Branches, and if the Plants are carefully managed, they will continue flowering until *December*; and during this Time they will afford as much Pleaſure as moſt other Exotick Plants, their Flowers growing in cloſe Bunches, and are, for the moſt part, of a very beautiful Colour; but theſe Plants rarely produce good Seeds in this Country.

The Soil in which theſe Plants thrive beſt, is the following Mixture, *viz.* one Load of freſh light Earth, one Load of very rotten Dung, or Tanners-Bark, and a Load of Sea-Sand; theſe ſhould be well mix'd and laid in a Heap three or four Months before it be us'd, obſerving to turn it over often, to ſweeten and mix the Parts, as alſo to prevent Weeds from growing thereon; and before it be put into the Pots, it ſhould be ſcreen'd roughly, juſt to ſeparate the large Stones and Clods from it; but by no means ſift it very fine; for when it is rendered very fine, the often watering of the Plants will cauſe it to join and conſolidate into one intire Maſs, whereby the Moiſture will be detain'd, which will rot the tender Fibres of the Roots, ſo that the Plants will grow ſickly, and if not remedied, ſhortly decay.

The ninth Sort grows plentifully in *South Carolina* and *Georgia*, from whence the Seeds have been brought to *England*. This riſes to the Height of eight or nine Feet, and divides into many Branches near the Ground. The Leaves which are produced by Pairs, are ſomewhat like thoſe of the *European* Kind. The Flowers are produced in ſmall Umbels from the Wings of the Leaves, which are of a purpliſh Colour. Theſe are rarely ſucceeded by Fruit in *England*, becauſe it is generally late in *Summer* before the Flowers appear; ſo that if the *Autumn* is not very favourable, the Flowers fall off without producing Seeds.

This Plant is hardy enough to live abroad in the open Air in *England*, provided it is planted in a ſheltered Situation; for as it naturally grows in Woods, where it is ſheltered from Cold by taller Trees, ſo if it is placed in an open Situation, it is often injured by ſevere Froſts. It is commonly propagated by Seeds, which are procured from the Countries of its natural Growth: they ſhould be ſown in Pots filled with freſh Earth early in the *Spring*, and then plunged into a Hot-bed of Tanners-bark. Theſe Pots muſt be conſtantly watered every other Day, or at leaſt twice a Week, according as the Earth dries; for if it is not kept pretty moiſt, the Seeds will remain a long time in the Ground, before they vegetate. When the Plants come up, they muſt be kept clean from Weeds, and in warm Weather ſhould have a large Share of Air admitted to them otherwiſe they will draw up very weak. They muſt alſo be duly watered, for they naturally grow on moiſt Places, and are pretty droughty Plants. About the middle of *June*, they muſt be inured to the open Air by Degrees. In *July* the Pots ſhould be taken out of the Hot-bed, and placed in a ſheltered Situation in the open Air; where they may remain till *October*, when the Pots ſhould be placed under a common Hot-bed Frame, where the Plants may be covered in froſty Weather; but when the Weather is mild, they ſhould be expoſed as much as poſſible. This Plant ſheds its Leaves in *Autumn*; and the latter End of *March*, or the Beginning of *April*, it puts out new Leaves; ſo ſhould be tranſplanted, juſt before the Buds begin to come out. Some of them ſhould be planted into ſeparate ſmall Pots filled with freſh light Earth; and the others may be put into a warm Border of freſh light Earth, where they may remain two Years to get Strength; and then they may be removed to the Places where they are deſigned to remain. Thoſe which are potted, ſhould be plunged into an old Bed of Tanners-bark, and covered either with Mats or Glaſſes, until they have taken new Root; and then they may be placed in the open Air with other hardy Exoticks, where they may remain during the *Summer* Seaſon; but in *Winter* they ſhould be ſheltered under a Hot-bed Frame as before. When they have obtained Strength, they may be ſhaken out of the Pots, and planted in wilderneſs Quarters, reſerving two or three Pots to be ſheltered in *Winter*, for fear thoſe abroad ſhould be deſtroyed by ſevere Froſt.

Theſe Plants may alſo be propagated by laying down of the young Branches, in the ſame manner as is practiſed for the common Sort. The beſt Time for laying them down, is in *March*, juſt before the Leaves come out. If theſe are duly watered in dry Weather, they will be ſufficiently rooted by the following *Spring*, when they may be taken off, and treated in the ſame manner as the ſeedling Plants.

The tenth Sort is very tender. The Seeds of this Kind were ſent from *Campechy* by Mr. *Robert Millar*, who found the Plants growing in low marſhy Places in great Plenty. This Sort riſes to the Height of eight or ten Feet, and has broader Leaves than the common Sort, which are (while young) covered pretty thick with a ſoft white Down; but as the Leaves grow older, their upper Sides are greener, and loſe moſt of the Down. The young Branches are alſo very woolly; but as theſe grow older it falls off. The Flowers are produced from the Wings of the Leaves in large Bunches, which are white; but the Apices or Summits are of a red Colour, which at a ſmall Diſtance appears like Stripes in the Flowers. After the Flowers are decayed, the Fruit appears, which, when ripe, turns black.

This Plant may be propagated by Seeds, which ſhould be ſown on a Hot-bed early in the *Spring*; and when the Plants are come up, and fit to tranſplant, they ſhould be each planted into a ſeparate ſmall Pot filled with light rich Earth, and then plunged into a Hot-bed of Tanners-bark, obſerving to ſhade them from the Sun until they have taken new Root, when they ſhould have free Air admitted to them every Day in proportion to the Warmth of the Seaſon; and as they are Plants which delight in low marſhy Places, ſo they muſt be conſtantly ſupplied with Water in hot Weather, otherwiſe they will not thrive. When they have filled the ſmall Pots with their Roots, they ſhould be ſhaken out, and their Roots trimm'd, and then put into Pots a Size larger; but they muſt be plunged again into the Hot-bed, becauſe while they are young they will not thrive, if they are too much expoſed to the open Air; tho' in warm Weather the Glaſſes ſhould be every Day raiſed with Stones, to admit freſh Air, otherwiſe they will draw up too weak. At *Michaelmas* they ſhould be removed out of the Hot-bed, and plunged into the Bark-bed in the Stove, where they ſhould be kept in a moderate Temperature of Heat, and muſt be frequently watered; in which Stove they will retain their Leaves all the Year, and make conſiderable Progreſs; ſo that in two Years from ſowing, they will produce Flowers and Fruit.

As theſe Plants grow older and ſtronger, ſo they may be treated more hardily: therefore they may be placed in a dry Stove in *Winter*; and in the Middle of *Summer* may be expoſed abroad in a warm ſheltered Situation, with other tender exotick Plants, obſerving in dry Weather to water them duly, and to ſhift them into other Pots, as they ſhall require it: with which Management they will produce their Flowers every Year toward the End of *Summer*; and if the *Autumn* proves very favourable, or the Plants are early removed into the Stove, they will perfect their Seeds very well.

This Sort may alſo be propagated by Layers, as the ninth; but when the Shoots are laid down, it will be proper to plunge the Pots into a moderate Hot-bed of Tanners-bark, which will cauſe them to put out Roots much ſooner than when they are expoſed abroad. The Layers, when ſufficiently rooted, may be taken off, and planted into ſeparate Pots, and treated in the ſame manner as the ſeedling Plants.

VICIA; [ſo called of *Vincire*, *Lat.* to *bind*, becauſe it clings about any Stays or Supporters] Vetch.

The *Characters* are;

It hath a papilionaceous Flower, out of whoſe Empalement ariſes the Pointal, which afterwards becomes a Pod full of roundiſh or angular Seeds; to which muſt be added, the Leaves grow as it were by Pairs, on a Middle-rib ending in a Tendril.

The *Species* are;

1. VICIA *ſativa vulgaris, ſemine nigro. C. B. P.* Common Vetch *or* Tare.

2. VICIA *ſativa alba. C. B. P.* White Vetch *or* Tare.

3. VICIA *ſupina, latiſſimo folio non ſerrato. Tourn.* Low Vetch, with a broad Leaf not ſerrated.

4. VICIA *ſupina, latiſſimo folio ſerrato. Tourn.* Low Vetch, with a broad ſerrated Leaf.

5. VICIA *ſiliquas ſupra infraque terram edens. Tourn.* Eatable Vetch, having Pods both above and below Ground.

6. VICIA *multiflora. C. B. P.* Many-flowered Vetch.

7. VICIA *maxima dumetorum. C. B. P.* Buſh or perennial Vetch.

8. VICIA *ſepium folio rotundiore acuto, ſemine nigro. C. B. P.* Buſh Vetch, with a rounder ſharp-pointed Leaf, and a black Seed.

9. VICIA *vulgaris, acutiore folio, ſemine parvo nigro. C. B. P.* Wild Vetch, with a ſharper pointed Leaf, and a ſmall black Seed.

10. VICIA *perennis incana multiflora. Bot. Monſp.* Hoary perennial Vetch, with many Flowers.

11. VICIA *perennis multiflora, majori flore cæruleo, ex albo mixto. Bot. Monſp.* Tufted perennial Vetch, with a large blue Flower mixed with white.

12. VICIA *perennis multiflora incana, inſularum Stæchadum. Inſt. R. H.* Perennial hoary tufted Vetch of the *Stæchades*.

13. VICIA *ſylveſtris hirſuta incana. C. B. P.* Hoary rough wild Vetch.

14. VICIA *ſylveſtris incana, major & præcox, Pariſienſis, flore ſuave-rubente. Inſt. R. H.* The greater early hoary wild Vetch, with a ſoft red Flower.

15. VICIA *ſylvatica maxima, piſo ſylveſtri ſimilis. J. B.* The greateſt wild Vetch, reſembling wild Peaſe.

16. VICIA *ſylveſtris lutea, ſiliqua hirſuta. C. B. P.* Wild yellow Vetch, with hairy Pods.

17. VICIA *ſerotina perennis, flore luteo, ſiliqua hirſuta. Inſt. R. H.* Late-flowering perennial Vetch, with a yellow Flower, and a hairy Pod.

18. VICIA *ſerotina perennis, flore luteo, ſiliqua glabra. Inſt. R. H.* Late-flowering perennial Vetch, with a yellow Flower, and ſmooth Pod.

19. VICIA *ſylveſtris lutea, cum galea fuſca. J. B.* Wild yellow Vetch, with a brown Standard.

20. VICIA *Cretica multiflora latifolia, flore intenſe purpureo. Tourn. Cor.* Broad-leav'd many-flower'd Vetch of Crete, with a deep purple Flower.

21. VICIA *orientalis multiflora incana, anguſtiſſimo folio. Tourn. Cor.* Hoary eaſtern tufted Vetch, with a very narrow Leaf.

22. VICIA *verna villoſiſſima & incana, flore parvo ſpicato ex purpureo ad ianthinum vergente. Tourn. Cor.* The moſt hairy and hoary ſpring Vetch, with a ſmall ſpiked Flower, from a purple to a violet Colour.

23. VICIA *multiflora ſpicata, floribus albidis, calyce purpureo. Tourn. Cor.* Spiked tufted Vetch, with whitiſh Flowers, and a purple Empalement.

24. VICIA *orientalis multiflora argentea, flore variegato. Tourn. Cor.* Eaſtern tufted ſilvery Vetch, with a variegated Flower.

25. VICIA *orientalis, flore maximo palleſcente, maculâ luteâ notato. Tourn. Cor.* Eaſtern Vetch, with a large pale Flower ſpotted with Yellow.

26. VICIA *multiflora Caſſubica fruteſcens, lentis ſiliqua. Breyn. Prod.* Shrubby tufted Vetch, with Pods like Lentils.

27. VICIA *ſylvatica multiflora maxima. Phyt. Brit.* The greateſt tufted wood Vetch.

28. VICIA *ſegetum, cum ſiliquis plurimis hirſutis. C. B. P.* Small wild Tare, with many rough Pods.

29. VICIA *ſegetum, ſingularibus ſiliquis glabris. C. B. P.* Corn Vetch, or fine Tare, with ſingle ſmooth Pods.

30. VICIA *minima, cum ſiliquis glabris. Inſt. R. H.* The ſmalleſt Vetch, with ſmooth Pods.

31. VICIA *ſive cracca, foliis & ſiliquis longioribus. Bot. Monſp.* Vetch with longer Leaves and Pods.

32. VICIA *minima præcox, Pariſienſium. H. R. Par.* The leaſt early Vetch, with an angular Seed.

The firſt Sort is cultivated in the Fields in divers Parts of *England* for the Seed, which is the common Food of Pigeons: The Method of cultivating them being much the ſame as is practiſed for *Peas*, I ſhall not repeat it in this Place, but refer the Reader to that Article.

The ſecond Sort is a Variety of the firſt, from which it only differs in the Colour of the Flowers and Seeds, which in this Kind are both white; but the Flowers of the other Kind are purple, and the Seeds are black. This may be cultivated as the former.

The third and fourth Sorts are, at preſent, only preſerved in Botanick Gardens in *England*, tho' I believe they might be cultivated in the Fields, as the common Sort, with good Succeſs.

Theſe muſt be ſown in the *Spring*, as *Peas*, but ſhould have a light dry Soil, and do require more Room than the common Sort, for the Plants are apt to ſpread pretty far, provided they like their Situation. They are both annual Plants, which decay ſoon after their Seeds are ripe. Theſe are ſuppoſed to be the *Bean* of the ancient *Greeks*.

The fifth Sort was carried from *Africa* into the *Weſt-Indies* (by the *Negroes*, who are very fond of its Fruit) where it thrives prodigiouſly; and when once well fixed in the Ground, will propagate itſelf very faſt; for ſoon after the Flowers fade, the Pedicle thruſts itſelf under the Surface of the Earth, where the Fruit is perfected; which if not ſought for, and taken up when ripe; will ſoon ſhoot out and make freſh Plants: So that the Perſons who have not been acquainted with this Plant, ſeldom know how and when to look for their Pods, by which Means the *Negroes* generally gather them for their own Uſe. This Plant is alſo an Inhabitant of the *Eaſt-Indies*, and alſo in divers Parts of *Aſia* hath been long cultivated; tho' there ſeems to be no extraordinary Quality in it to recommend it. In *England* it is only preſerved as a Curioſity, and muſt have the Aſſiſtance of a Hot-bed, otherwiſe the Fruit will not ripen.

The ſixth Sort grows wild in divers Parts of *England*, under Hedges, and by the Sides of Woods, where it climbs upon whatever Buſhes are near it; and during the Time of flowering (which is commonly in *June* and *July*) it affords an agreeable Proſpect. This Plant may be cultivated by the Sides of Wilderneſs Quarters, where it may be allowed to climb upon ſome low Buſhes, without which Support it ſeldom thrives well; and in ſuch ſhady Situations it will flower extremely, and continue for ſeveral Years. The beſt Way to propagate it, is by ſowing the Seeds either in *Spring* or *Autumn*, in the Places where they are to remain; for theſe Plants commonly ſhoot their Roots downright into the Ground, ſo that they ſeldom thrive well if tranſplanted.

The ſeventh, ninth and ſixteenth Sorts grow wild in this Kingdom. The ſeventh is very common in ſhady Woods, and on the Sides of Banks under Trees, in moſt Parts of *England*. The ninth Sort is found on *Shotover Hill*, and in ſome other Places in *England*: And the ſixteenth grows on *Glaſtenbury-thorn-hill* in *Somerſetſhire*.

The eighth, tenth, eleventh, thirteenth, fifteenth, ſeventeenth, eighteenth and nineteenth Sorts grow wild in *Germany*, *France* and *Italy*, but are not Natives of this Country. Theſe are all of them abiding Plants, whoſe

Roots continue ſeveral Years; but their Shoots die down in *Autumn*, and freſh ones come out the following *Spring*, ſome of which will riſe to the Height of five or ſix Feet, and trail over Buſhes, or whatever Plants they grow near; ſo that they muſt be ſupported, otherwiſe they will appear very unſightly.

Theſe may be propagated by Seeds, which may be ſown in Drills on a Border of freſh Earth, expoſed only to the Morning Sun. The beſt Time for ſowing theſe Seeds is in *March*, and when the Plants come up, they muſt be kept clean from Weeds; and where they are too cloſe together, ſome of them ſhould be drawn up to give Room for the remaining ones to grow ſtrong. This is all the Culture they require till *Michaelmas*, when their Shoots will decay; at which Time the Roots ſhould be carefully taken up, and tranſplanted where they are deſign'd to remain, which ſhould be under Trees, and in other ſhady Wilderneſs Quarters; where, if they are rightly diſpoſed, they will thrive extremely well, and make an agreeable Variety.

The twelfth Sort grows wild in the *Stœchades Iſles*, from whence the Seeds have been obtained by ſome curious Perſons, who preſerve the Sort for the ſake of Variety; as is alſo the fourteenth Sort, which is found wild in the Neighbourhood of *Paris*.

The twentieth, twentyfirſt, twentyſecond, twentythird, twentyfourth and twentyfifth Sorts were diſcovered by Dr. *Tournefort* in the *Levant*, from whence he ſent their Seeds to the Royal Gardens at *Paris*. Theſe, tho' they are Natives of warmer Countries than *England*, yet will thrive very well in the open Air; ſo may be admitted into Gardens for the ſake of Variety.

The twentyſixth Sort is alſo an abiding Plant, whoſe Shoots decay every *Autumn*, and freſh ones are produced in the *Spring*. This Sort ſhould have a moiſt ſhady Situation, in which the Shoots will riſe five or ſix Feet high, and produce great Quantities of Flowers; ſo will afford an agreeable Variety in ſome obſcure Places, where few better Plants will thrive.

The twentyſeventh Sort grows wild in ſome Woods in the North of *England*, as alſo in *Oxfordſhire*. This is alſo an abiding Plant, which ſhould be treated in the ſame Manner as the former Sort.

As all theſe Sorts of Vetches grow near Buſhes, or under Hedges, on which they climb, and are thereby ſupported from trailing on the Ground, ſo whenever they are brought into Gardens, they ſhould be planted in the like Situation: For if they trail on the Ground, they will run over whatever Plants grow near them, and make a bad Appearance; whereas, if they are planted near any ordinary Shrubs, over which they may be allowed to ramble, their Flowers will appear ſcattering amongſt the Branches of the Shrubs, and afford an agreeable Variety.

The twentyeighth, twentyninth, thirtieth and thirtyfirſt Sorts are annual Plants, which grow too plentifully amongſt the Corn, ſo as to become very troubleſome Weeds in ſome Parts of *England*; therefore ſhould be rooted out in the *Spring*, before their Seeds ripen; for if any of them are permitted to ſtand until their Seeds are ripe, the firſt hot Day after, the Pods will burſt, and caſt their Seeds to a great Diſtance, ſo as to fill the Ground with young Plants in *Autumn*. Theſe Plants always come up in *Autumn*, and abide the *Winter*, during which Time they do not appear as if they would ever become large enough to injure the Crop, amongſt which they grow; but in the *Spring* they will ſend forth many lateral Shoots, ſo as to ſpread to a conſiderable Diſtance, and by their Tendrils will faſten themſelves to the Stalks of Corn, or any other Plants, and thereby greatly weaken them; and ſometimes, where theſe Weeds are in Plenty, and the Corn but weak, they will ramp quite over it, and thereby almoſt deſtroy it. The beſt Time to extirpate theſe Weeds is in *March* or *April*, when, if they are cut up with a Spaddle in dry Weather, they will in a Day or two be effectually deſtroy'd, ſo as not to recover; and if this be repeated two or three Seaſons, it will entirely clear the Land of them.

The thirtyſecond Sort is a very ſmall annual Plant, which grows wild on chalky Hills in ſome Parts of *England*, but particularly near *Greenhith* in *Kent*. It flowers the Beginning of *April*, the Seeds are ripe in *May*, and the Plant ſoon after periſhes; ſo that whoever is deſirous to find it, muſt ſearch for it while it is in Vigour; otherwiſe it is ſo ſmall, that it can hardly be diſcovered. If this Plant is deſigned to be preſerved in a Garden, the Seeds ſhould be ſown early in *Autumn*, that the Plants may get Strength before *Winter*; for when they are ſown in the *Spring*, they ſeldom ſucceed. When they are once eſtabliſhed in a Garden, and their Seeds permitted to ſcatter, they will maintain themſelves better than if ſown by Hand; and will require no other Care, but to keep them clear from Weeds.

There are ſome of the larger Kinds of theſe Vetches, as well worth cultivating in the Fields as the common *Tare*, and will ſerve for the ſame Purpoſes, eſpecially the eighth, ninth and fifteenth Sorts, which grow large, and afford a good Quantity of Seeds. Theſe may all be cultivated in the ſame Manner as the common Sort, and are equally hardy.

The uſual Time for ſowing of Vetches or Tares is in the *Spring*, about the Middle of *February*; but from ſeveral Experiments which I have made, I find it to be a much better Method to ſow them in *Autumn*; for as they are hardy enough to reſiſt the Froſt in *Winter*, ſo they will get Strength early in the *Spring*, and will grow conſiderably larger than thoſe which are ſown in the *Spring*, and will produce a larger Quantity of Seeds, which will ripen early in *Summer*, ſo may be gather'd in before Wheat Harveſt.

The Sorts of Vetches which are cultivated for Uſe in the open Fields, ſhould be ſown in Drills, after the ſame Manner as is practiſed for Peaſe. Theſe Drills ſhould be a Foot and half or two Feet aſunder, that there may be Room for the Houghing Plough to go between them, in order to deſtroy the Weeds, and to earth the Plants. Theſe Drills ſhould be about the ſame Depth as thoſe uſually made for Peaſe, and the Seeds ſhould be ſcattered about the ſame Diſtance in the Drills. Theſe Seeds ſhould be carefully covered as ſoon as they are ſown; for if they are left open the *Rooks* will diſcover them; ſo that where they are not carefully watch'd, they will entirely devour them. Indeed theſe, being ſown in *Autumn*, will be in leſs Danger than thoſe which are ſown in the *Spring*; becauſe there is more Food for *Rooks* and *Pigeons* in the open Fields at this Seaſon; and the Plants will appear much ſooner above Ground. The beſt Time to ſow them is about the Beginning of *September*; for the Rains which uſually fall at that Seaſon, will bring them up in a ſhort Time. Toward the latter End of *October*, the Plants will have obtained conſiderable Strength, ſo ſhould then be earthed up with the Houghing Plough. This Work ſhould be performed in dry Weather, and in doing of it Care muſt be had to lay the Earth up as high to the Stems of the Plants as poſſible, ſo as not to cover their Tops; becauſe this will ſecure them againſt Froſt. The whole Space of Ground between the Rows ſhould alſo be ſtirred, in order to deſtroy the Weeds, which if carefully performed in dry Weather, will lay the Land clean till *March*; at which Time the Crop ſhould be earthed a ſecond time, and the Ground clean'd again between the Rows; which will cauſe the Plants to grow vigorous, and in a little Time they will ſpread ſo as to meet and cover the Spaces; whereas thoſe ſown in the *Spring* will not grow to half this Size, and will be very late in flowering.

Some People ſow theſe Vetches, and when they are fully grown, plough them into the Ground, in order to manure it. Where this is deſigned, there will be no Occaſion to ſow them in Drills at this Diſtance, nor to huſband them in the Manner before directed; but in this Caſe it will be the beſt Method to ſow them in *Autumn*, becauſe they will be fit to plough in much ſooner the following Year, ſo that the Land may be better prepared to receive the Crops for which it is intended. In ſome Parts of *France*, and in *Italy*, theſe Vetches are ſown for feeding of Cattle while green, and are accounted very profitable; but in thoſe Countries Graſs is more ſcarce than in *England*, ſo that I think it would not anſwer to ſow them for this Purpoſe here.

Where theſe Plants are cultivated for their Seeds, they ſhould be cut ſoon after the Pods change brown; and when they are dry, they muſt be immediately ſtack'd; for if they are ſuffered to lie out in the Field to receive Wet, and there comes one hot Day after it, the Pods will moſt of them burſt, and caſt out the Seeds. When the Seeds are threſhed out, the Haulm is eſteemed very good Food for Cattle, and ſome have recommended the Seeds for Horſes, and affirm they are as proper for thoſe Animals as Beans; which, if true, will render them more valuable, becauſe theſe will grow on the lighteſt ſandy Land, where Beans will not thrive; ſo may be a good Improvement to ſome Counties in *England*, where they do not attempt to cultivate Beans.

The perennial Sorts are not proper to cultivate in the Fields, becauſe they are of ſlower Growth than the annual Kinds; for they make but little Progreſs the firſt Year they are ſown, and moſt of them delight in ſhady Places, and to grow under Buſhes on which they can ramp; ſo that when they grow in the open Ground, their Branches trail; and in wet Weather, if they are cloſe together, they will rot. So that the annual Kinds of large Growth are ſuch as ſhould be preferred for ſowing. But of all the Sorts, there is not one ſo good as that with white Seeds.

VINCETOXICUM; *vide* Aſclepias.

VINE; *vide* Vitis.

VIOLA; *vide* Violet.

The *Characters* are;

It hath a polypetalous, anomalous Flower, ſomewhat reſembling the papilionaceous Flower; for its two upper Petals, in ſome meaſure, repreſent the Standard, the two ſide ones the Wings; but the lower one, which ends in a Tail, in ſome meaſure reſembles the Keel; out of the Empalement ariſes the Pointal, which afterwards becomes a Fruit, for the moſt part, three corner'd, opening into three Parts, and full of roundiſh Seeds.

The *Species* are;

1. VIOLA *Martia purpurea, flore ſimplici odoro. C. B. P.* Common purple Violet, with a ſweet-ſcented Flower.

2. VIOLA *Martia major hirſuta inodora. Mor. Hiſt.* Greater hairy March Violet without Smell.

3. VIOLA *Martia inodora ſylveſtris. C. B. P.* Wild *or* Dogs Violet.

4. VIOLA *Martia alba. C. B. P.* White ſweet-ſcented Violet.

5. VIOLA *Martia, multiplici flore. C. B. P.* Double purple Violet.

6. VIOLA *Martia, flore multiplici candido. C. B. P.* Douwhite Violet.

7. VIOLA *Martia, folio eleganter variegato, flore albo.* March Violet, with a beautiful variegated Leaf and a white Flower.

8. VIOLA *Martia, flore rubello.* March Violet, with a reddiſh-colour'd Flower.

9. VIOLA *erecta, flore cæruleo. Mor. Hiſt.* Upright Violet, with a blue Flower.

10. VIOLA *montana lutea grandiflora. C. B. P.* Mountain Violet, with a large yellow Flower.

11. VIOLA *tricolor hortenſis repens. C. B. P.* Panſies, Hearts-eaſe, *or* three-colour'd Violet, *commonly called* Three Faces under a Hood.

12. VIOLA *Martia hortenſis, foliis amplioribus. C. B. P.* Garden March Violet, with larger Leaves.

13. VIOLA *Martia inodora ſylveſtris, foliis mucronatis, oblongis & ſtrictioribus. C. B. P.* Dog's Violet, with oblong and narrow pointed Leaves.

14. VIOLA *Martia ſylveſtris æquatè cærulea, folio & flore minore. Hort. Cath.* Blue wild Violet, with a ſmaller Leaf, and Flower.

15. VIOLA *Martia, multiplici flore [illegible]bello. C. B. P.* March Violet, with a double reddiſh Flower.

16. VIOLA *Martia, multiplici flore ex albo & purpureo variegato. C. B. P.* March Violet, with a double Flower, variegated with white and Purple.

17. VIOLA *Martia multiplex, flore cinereo. H. R. Par.* Double March Violet, with an aſh-coloured Flower.

18. VIOLA *flore pleno maximo. J. B.* The largeſt double Violet.

19. VIOLA *Martia intensè purpurea, flore minore pleno. J. B.* March Violet, with a ſmall double Flower, of a deep purple Colour.

20. VIOLA *paluſtris rotundifolia glabra. Mor. Hiſt.* Smooth round-leav'd marſh Violet.

21. VIOLA *Alpina, folio in plures partes diſſecto. C. B. P.* Alpine Violet, with a Leaf cut into many Parts.

22. VIOLA *Alpina purpurea, exiguis foliis. C. B. P.* Purple Violet of the Alps, with ſmall Leaves.

23. VIOLA *Alpina rotundifolia lutea. C. B. P.* Yellow Violet of the *Alps*, with a roundiſh Leaf.

24. VIOLA *montana pumila anguſtifolia, flore niveo inodoro. C. B. P.* Mountain dwarf narrow-leav'd Violet, with a ſnow-white Flower without Smell.

25. VIOLA *Martia arboreſcens lutea. Tabern. [illegible]n.* Yellow tree-like March Violet.

26. VIOLA *montana tricolor odoratiſſima. C. B. P.* The moſt ſweet ſmelling three-coloured mountain Violet.

27. VIOLA *montana alba grandiflora. C. B. P.* Great flowered white mountain Violet.

28. VIOLA *montana lutea, ſubrotundo crenato folio. Barr. Icon.* Yellow mountain Violet, with a roundiſh notched Leaf.

29. VIOLA *montana cærulea grandiflora. H. R. Par.* Great flowered blue mountain Violet.

30. VIOLA *montana lutea, foliis non crenatis. C. B. P.* Yellow mountain Violet, with Leaves not notch'd.

31. VIOLA *montana tricolor, flore variegato. Inſt. R. H.* Three-coloured mountain Violet, with a ſtrip'd Flower.

32. VIOLA *Hiſpanica fruticoſa longifolia. Inſt. R. H.* Long-leav'd ſhrubby Spaniſh Violet.

33. VIOLA *Pyrenaica, longius caudata, teucrii folio. Inſt. R. H.* Pyrenean Violet, with a long Tail, and a tree-germander Leaf.

34. VIOLA *Ætnica erecta bicolor hirſuta minima elatior ac ramoſior. Hort. Cath.* Upright two-coloured hairy very ſmall Violet of Ætna, taller and more branching.

35. VIOLA *arvenſis, flore toto luteo. C. B. P.* Field Violet, with a Flower all yellow.

36. VIOLA *cærulea maxima, cucumerinis hirſutis foliis, Virginiana. Pluk. Phyt.* The largeſt blue Violet of Virginia, with hairy cucumber Leaves.

37. VIOLA *maxima, cucumerinis hirſutis foliis, Virginiana, flore luteo. Pluk. Alm.* The largeſt Violet of Virginia, with hairy cucumber Leaves, and a yellow Flower.

38. VIOLA *Virginiana, platani ferè foliis, parvis & incanis. Pluk. Mantiſſ.* Virginian Violet, with ſmall hoary Leaves, ſhap'd like thoſe of the Plain-tree.

39. VIOLA *Cretica ſaxatilis lutea odoratiſſima, leucoii foliis. Tourn. Corn.* Rock Violet of Crete, with a very ſweet yellow Flower, and wall-flower Leaves.

40. VIOLA *orientalis montana grandiflora, violacei coloris. Tourn. Cor.* Mountain eaſtern Violet, with a large Flower of a purple Colour.

41. VIOLA *Martia Virginiana minor, foliis longius mucronatis, flore purpureo, inodora.* Small Virginian Violet, with long-pointed Leaves, and a purple Flower without Smell.

The firſt Sort here mentioned is very common in Woods and ſhady Lanes in divers Parts of *England*, and is what ſhould always be us'd in Medicine; though ſometimes the People who ſell theſe Flowers in the Markets, do many times impoſe upon the Ignorant, the Flowers of the ſecond Sort, which are much larger than thoſe of the firſt, and fill up the Meaſure better: but they having no Smell, are very improper for Uſe.

All the eight firſt Sorts are pretty Varieties in a Garden; where, being planted under Hedges, in Wilderneſſes, or other ſhady Places, they will thrive exceedingly, and will want no other Culture than only to keep them clear from Weeds; and in the *Spring*, when they are in Flower, they caſt forth a moſt agreeable Perfume, eſpecially in Mornings or Evenings, ſo that it renders ſuch Places very delightful at that Seaſon.

Theſe may be eaſily propagated by parting their Roots. The beſt Time for which is at *Michaelmas*, that the Plants may take Root before *Winter*, ſo that they may flower ſtronger the ſucceeding *Spring*.

The Double Sorts, and thoſe without Smell, may be admitted for Variety: But the ſingle blue, white, and reddiſh coloured Sorts, are thoſe which ſhould be moſt cultivated; becauſe theſe are equally well-ſcented, in which the greateſt Curioſity of theſe Flowers conſiſts. And theſe all growing wild in *England*, may be eaſily obtained in Quantity from their Places of Growth, by ſuch who are fond of theſe Flowers.

The ninth Sort is preſerved in ſome curious Gardens for Variety, but there is no Scent in its Flowers, ſo that it hardly merits a Place in curious Flower-Gardens.

The tenth Sort produces large yellow Flowers, which continue a long Time: This being a Native of cold mountainous Places, ſhould have a ſhady cool Situation, and is very proper for North Borders, where it will thrive exceedingly, add continue flowering moſt part of the *Summer*. It is propagated by parting of the Roots in the ſame manner as the former.

The eleventh Sort is admitted into Gardens for the beautiful Colours of its Flowers, of which there are a great Number of Varietes, but they have no Scent. This Plant is annual, but will require no other Culture than only to place a few Roots in ſuch Parts of the Garden where you would have them grow, and ſuffer them to ſhed their Seeds, which will come up and multiply faſt enough; therefore you muſt obſerve to reduce them within Compaſs, otherwiſe they will ſpread over the whole Garden. This Plant is placed amongſt the Officinal Simples in the *College Diſpenſatory*.

The twelfth and following Sorts of Violets, are preſerved in ſome curious Gardens for the ſake of Variety. They are all hardy enough to thrive in the open Air in *England*; but thoſe Sorts which are Natives of the *Alps*, and other mountainous Places, muſt be planted in a ſhady Situation, and ſhould have a pretty ſtrong moiſt Soil, otherwiſe they will not thrive.

The twelfth Sort differs from the common Violet, only in having larger Leaves, which may proceed from the Culture, for I have frequently obſerved, when the Roots of Violets have been gathered in the Woods, and brought into Gardens, that their Leaves have been greatly inlarged in one Year; but then they have not been ſo productive of Flowers as before.

The thirteenth, fourteenth, twentieth, twenty-firſt, twenſecond, twenty-third, twenty-fourth, thirty-ſecond, thirty-third, thirty-fourth, thirty-fifth, thirty-ſixth, thirty-ſeventh, thirty-eighth and forty-firſt Sorts, are Plants of no great Beauty, ſo are only preſerved for the ſake of Variety by ſome curious Perſons; but the fifeenth, ſixteenth ſeventeenth, eighteenth and nineteenth Sorts, merit a Place in every good Garden, for the ſake of their double Flowers, which are extremely ſweet. The eighteenth Sort produces very large full Flowers, which are almoſt as large as the double *Cinnamon-roſe*; ſo that they make a fine Appearance, and the Flowers are alſo very ſweet. This Plant ſhould be planted on a ſtrong Soil in a ſhady Situation, where they will thrive and flower much better than in a rich Ground.

The twenty-ſixth, twenty-ſeventh, twenty-eighth, twenty-ninth, thirtieth and thirty-firſt Sorts, are alſo very pretty Plants; ſo may be allowed a Place in a North Border in the Flower-garden, for the ſake of Variety. Theſe are of the Kind of the *Panſies* or *Hearts-eaſe*, but their Flowers are much larger; and as their Roots abide ſeveral Years, ſo they may be propagated by parting of their Roots. The beſt Time for this Work is at *Michaelmas*, that they may be well rooted before *Spring*, otherwiſe they will not flower very ſtrong the following *Spring*.

The thiry-ninth and fortieth Sorts were diſcovered by Dr. *Tournefort* in the *Levant*. Theſe, tho' they are Natives of warmer Countries, yet they will thrive very well in the open Air in *England*. Theſe muſt alſo be planted in a ſhady Border, and in dry Weather they ſhould be often watered, which will continue their Flowers a long time: for as theſe are alſo of the *Panſy* Kind, ſo they in like manner continue to produce new Flowers, from the Wings of the Leaves, for at leaſt two Months, if they are not ſtunted by Drought. The thirty-ninth Sort, having very ſweet Flowers, well deſerves a Place in curious Gardens.

VIORNA; *vide* Clematitis.

VIRGA AUREA; [This Plant is ſo called becauſe the Stalk reſembles a Rod, and its Flower is of a golden Colour] Golden-Rod.

The *Characters* are:

The Leaves are for the moſt part whole, and are placed alternately on the Stalks; the Calix (or Flower-cup) is ſquamous; the Flowers are ſmall, radiated, and of a yellow Colour, conſiſting of many Florets, each of which is furniſhed with an Embryo, which afterwards becomes a Seed, having a downy Subſtance adhering to it: To which ſhould be added, that the Flowers are produced in a long Spike.

The *Species* are;

1. VIRGA AUREA *vulgaris latifolia. J. B.* The common *or* broad-leav'd Golden-Rod.

2. VIRGA AUREA *montana, folio anguſto ſubincano, floſculis conglobatis. Raii Syn.* Narrow-leav'd Mountain Golden Rod, with an hoary Leaf, and conglobate Flowers.

3. VIRGA AUREA *anguſtifolia, panicula ſpecioſa, Canadenſis. H. R. Par.* Narrow-leav'd Canada Golden-Rod, with a ſpecious Panicle.

4. VIRGA AUREA *Canadenſis hirſuta, panicula minus ſpecioſa. Boerh. Ind.* Rough Canada Golden-Rod, with a leſs ſpecious Panicle.

5. VIRGA AUREA *Novæ Angliæ altiſſima, paniculis nonnunquam reflexis. Flor. Bat.* The talleſt New-England Golden-Rod, with a reflex'd Panicle.

6. VIRGA AUREA *altiſſima ſerotina, panicula ſpecioſa patula. Rand.* Talleſt Late-flowering Golden-Rod, with a ſpecious ſpreading Panicle.

7. VIRGA AUREA *Virginiana, foliis anguſtioribus aſperis, panicula minus ſpecioſa. Pluk. Phyt.* Virginian Golden-Rod, with narrow rough Leaves, and a leſs ſpecious Panicle.

8. VIRGA AUREA *rugoſis foliis, Virginiana, panicula florum ampliſſima. Pluk. Phyt.* Rough-leav'd Virginian Golden-Rod, with an ample Panicle of Flowers.

9. VIRGA AUREA *foliis lævibus non ſerratis, panicula ſpecioſa floribus magnis. Flor. Bat.* Smooth-leav'd Golden-Rod, with a ſpecious Panicle, and large Flowers.

10. VIRGA AUREA *Marylandica, ſpicis florum racemoſis, foliis integris ſcabris. Mart. Hiſt. Rar. Plant.* Golden-Rod from Mary-land, with branching Spikes of Flowers, and whole rough Leaves.

11. VIRGA AUREA *Canadenſis, aſteriſci folio. Par. Bat.* Canada Golden-Rod, with a Leaf like Aſteriſcus.

12. VIRGA AUREA *Americana, ſerrata, floribus ad foliorum alas conglobatis. Breyn. Prod.* American Golden-Rod, with ſerrated Leaves and conglobated Flowers coming out from the Wings of the Leaves.

13. VIRGA AUREA *limonii folio, panicula uno verſu diſpoſita. H. R. Par.* Golden-Rod, with a Sea-Lavender-leaf, and the Flowers growing upon one Side of the Stalk.

14. VIRGA AUREA *Noveboracenſis glabra, caulibus rubentibus, foliis anguſtis glabris. Flor. Bat.* Smooth New-York Golden-Rod, with red Stalks, and narrow ſmooth Leaves.

15. VIRGA AUREA *floribus fiſtuloſis, ſenecionis inſtar, foliis anguſtioribus non ſerratis. Hiſt. Oxon.* Golden-Rod, with fiſtulous Flowers, ſomewhat like Groundſel, and narrow ſmooth Leaves.

16. VIRGA AUREA *Canadenſis, foliis carnoſis non ſeratis latioribus. Hiſt. Oxon.* Golden-Rod, with broad-fleſhy, ſmooth Leaves.

17. VIRGA AUREA *Novæ Angliæ, foliis longiſſimis glabris. Flor. Bat.* New-England Golden-Rod, with long, ſmooth Leaves.

18. VIRGA AUREA *latifolia ſerrata. C. B. P.* Golden-Rod with broad ſawed Leaves.

19. VIRGA AUREA *montana, latiore folio glabro. H. R. Par.* Mountain Golden-Rod, with a broad ſmooth Leaf.

20. VIRGA AUREA *montana, latiore folio hirſuto. H. R. Par.* Mountain Golden-Rod, with a broad hairy Leaf.

21. VIRGA AUREA *Alpina, laurinis rigidioribus foliis. Bocc. Muſ.* Alpine Golden-Rod, with ſtiffer Bay-leaves.

22. VIRGA AUREA *major, foliis glutinoſis & graveolentibus. Inſt. R. H.* Greater Golden-rod, with clammy and ſtinking Leaves.

23. VIRGA AUREA *minor, foliis glutinoſis & graveolentibus. Inſt. R. H.* Smaller Golden-Rod, with clammy and ſtinking Leaves.

24. VIRGA AUREA *major, foliis glutinoſis & graveolentibus, gallas ferens. Inſt. R. H.* Greater gall-bearing Golden-Rod, with clammy and ſtinking Leaves.

25. VIRGA AUREA *Virginiana annua. Zan.* Annual Virginian Golden-Rod.

26. VIRGA AUREA *Americana hirſuta, radice odorata. Joncq.* Rough American Golden-rod, with a ſweet-ſmelling Root.

27. VIRGA AUREA *Marylandica cæſia glabra. Hort. Elth.* Smooth Golden-rod of Mary-land.

28. VIRGA AUREA *Americana annua graveolens, flore minimo, foliis conjugatis, & hyperici modo perforatis. Houſt.* Annual ſtinking American Golden-Rod, with a very ſmall Flower, and Leaves growing by Pairs, which are perforated in the manner of St. John's-wort.

29. VIRGA AUREA *Americana, urticæ foliis rugoſis conjugatis & hirſutis, florum ſpicis folioſis. Houſt.* American Golden-Rod, with rough Nettle-leaves growing by Pairs, and the Spikes of Flowers ſet with ſmall Leaves.

30. VIRGA AUREA *Americana fruticoſa, ſalicis folio, floribus quaſi umbellatis. Houſt.* Shrubby American Golden-rod, with a Willow-leaf, and Flowers growing almoſt in an Umbel.

The ſeventeen firſt mentioned are the moſt valuable Sorts which I have yet ſeen in the *Engliſh* Gardens; the greateſt Part of which are Natives of *America*, from whence, it is very probable, there may be many other Sorts brought, ſince theſe Plants do propagate themſelves by ſhedding their Seeds, which is likely to produce new Varieties annually; as do moſt other Sorts of Plants, ſo that there may be no End to their Variety.

Theſe Plants are very great Ornaments in the Borders of large Flower-Gardens, where, by their Succeſſion of Flowering, they afford a very great Pleaſure; for the earlieſt Kinds begin to flower in *June*, which are ſucceeded by other Sorts until the latter End of *October*; and their Flowers being produced, for the moſt part, on long ſpecious Spikes or Panicles, do make a very handſome Appearance, and are very ornamental to Flower-pots, when intermixed with Flowers of different Colours to place in Rooms.

They are all eaſily propagated by parting their Roots in the *Spring*, before they begin to ſhoot, and ſhould be planted in the Middle of the larger Borders in the Flower-Garden: They will grow in almoſt any Soil or Situation, but will thrive beſt in a light freſh Earth, and an open Expoſure, tho' ſome of the hardieſt of them may be placed under Avenues of Trees, where they will continue in Flower a long time, and look very well. The firſt twelve Sorts are ſomewhat hardier than the reſt, and will increaſe very faſt by Off-ſets, which ſome of them ſend forth in very great Plenty, inſomuch, that if they are not carefully dug round at leaſt once in every Year, they will ſpread over the Borders where they are planted, and deſtroy ſuch Plants as ſtand near them. The other Sorts ſhould have a warmer Situation, and a dry Soil: theſe are not ſo apt to ſpread at their Roots as the others, ſo that there will be no Difficulty of keeping them within Bounds.

The firſt Sort here mentioned is ſometimes uſed in Medicine. This grows wild in moſt ſhady Woods in the South Parts of *England*; from whence the Roots may be tranſplanted into a ſhady Part of the Garden, where they will thrive and flower very well.

Theſe are all perennial Plants, which die to the Surface of the Ground every *Winter*, but riſe again the ſucceeding *Spring*: Moſt of them produce their Flowers in *Autumn*, and, if the Seaſon proves favourable, will ripen their Seeds; which, if ſown ſoon after ripe, will come up the following *Spring*, from whence ſome new Varieties may be obtained.

The eighteenth, nineteenth, twentieth, twenty-firſt, twenty-ſixth and twenty-ſeventh Sorts, are abiding Plants, which may be propagated by parting of their Roots, in the ſame manner as hath been directed for the Sorts firſt mentioned. Theſe Plants continue a long time in Flower, and appearing toward the latter Part of *Summer*, when there are few better Sorts in Beauty, are worthy of a Place in every large Garden, eſpecially as they are very hardy, and require very little Care to cultivate them; for they will thrive in the Shade under Trees, and if they are taken up and parted every fourth Year, they will thrive and flower extremely well.

The twenty-ſecond, twenty-third and twenty-fourth Sorts, ſeldom continue longer than two or three Years, ſo ſhould be often renewed. Theſe may be increaſed by parting of their Roots; but the Plants which are thus parted, ſeldom thrive ſo well as thoſe which are raiſed from Seeds; but as theſe Plants do not perfect their Seeds every Year in *England*, ſo the other Method muſt be practiſed to preſerve the Kinds. The beſt Time for this Work is in the *Autumn*, that they may be well rooted before the *Spring*, otherwiſe they will not flower very ſtrong. Theſe Sorts ſhould be planted on a loamy Soil on open Borders; for they will not thrive under the Drip of Trees.

The twenty-fifth Sort is an annual Plant of no great Beauty, which if permitted to ſcatter its Seeds, will become a Weed over the Garden. This Plant is now become a common Weed in the Fields in divers Parts of *England*; but it is generally believed, the Seeds were at firſt blown out of Gardens; for it was originally brought from *America*.

The twenty-eighth, twenty-ninth and thirtieth Sorts, were diſcovered by the late Dr. *Houſtoun* at *La Vera Cruz*. Theſe are tender Plants, ſo will not live in the open Air in *England*. They may be propagated by Seeds, which ſhould be ſown on a moderate Hot-bed early in the *Spring*; and when the Plants are come up, they ſhould be tranſplented into Pots filled with freſh Earth, and then plunged into a moderate Hot-bed of Tanners-bark; obſerving, after they have taken new Root, to admit a large Share of free Air to them every Day when the Weather is warm, as alſo to water them conſtantly every Day, for they naturally grow in moiſt Places. The twenty-eighth Sort, which is an annual Plant, will flower toward the Middle of *June*, and the Seeds will ripen the End of *Auguſt*; when ſome of them ſhould be ſown to come up before *Winter*, becauſe the Seeds will more certainly grow at this Seaſon, than in the *Spring*, and the Plants will grow much ſtronger. The twenty-ninth Sort is a biennial Plant, ſo it rarely flowers the firſt Seaſon; therefore this, and the thirtieth Sort, (which is an abiding Plant) ſhould be removed into the Stove at *Michaelmas*, and placed where they may have a temperate Degree of Warmth in *Winter*, in which they may be preſerved; but they muſt be frequently refreſhed with Water, tho' in very cold Weather it muſt not be given in great Quantities. With this Management the Plants will flower extremely well, and add to the Variety in the Stove.

VISCUM; [ſo call'd, becauſe its Fruit is full of a glutinous Subſtance] Miſleto.

The *Characters* are;

The Flower conſiſts of one Leaf, which is ſhaped like a Baſon, and for the moſt part divided into four Parts, and beſet with Warts; the Ovary, which is produced in the Female Flowers, is placed in a remote Part of the Plant from the Male Flowers, and conſiſts of four ſhorter Leaves; this afterwards becomes a round Berry, full of a glutinous Subſtance, incloſing a plain Heart-ſhap'd Seed.

We have but one *Species* of this Plant in *England*, viz.

VISCUM *baccis albis*. C. B. P. Common Miſleto, with white Berries.

This Plant is always produc'd from Seed, and is not to be cultivated in the Earth, as moſt other Plants, but will always grow upon Trees; from whence the Ancients accounted it a Super-plant, moſt of whom thought it was an Excreſcence on the Tree, without the Seed being previouſly lodg'd there: Which Opinion is now generally confuted from a repeated Number of Experiments.

The Manner of its being propagated is this, (*viz.*) The *Miſleto-Thruſh*, which feeds upon the Berries of this Plant, in *Winter*, when it is ripe, doth often carry the Seeds from Tree to Tree; for the viſcous Part of the Berry, which immediately ſurrounds the Seed, doth ſometimes faſten it to the outward Part of the Bird's Beak; which to get diſengag'd of, he ſtrikes his Beak againſt the Branches of a neighbouring Tree, and thereby leaves the Seed ſticking by this viſcous Matter to the Bark; which, if it lights upon a ſmooth Part of the Tree, will faſten itſelf thereto, and the following *Winter* will put out and grow, and in the ſame manner it may be propagated by Art; for if the Berries, when full ripe, are rubbed upon the ſmooth Part of the Bark of a Tree, they will adhere cloſely thereto, and, if not deſtroy'd, will produce Plants the following *Winter*.

The Trees which this Plant doth moſt readily take upon, are, the *Apple*, the *Aſh*, and ſome other ſmooth-rinded Trees; but I have ſeveral times try'd it upon the *Oak* without Succeſs, for the Bark of that Tree is of too cloſe a Texture to admit the Seeds ſtriking therein; which is alſo the Reaſon it is ſo rarely found upon that Tree: And notwithſtanding the great Encomiums which have been given to the *Miſleto* of the *Oak*, for its Medicinal Virtues, yet I can't help thinking, that it is equally good from whatever Tree it be taken, nor is it poſſible to find this Plant growing in any Quantity upon the *Oak*; ſo that thoſe Perſons who pretend to furniſh the Town with it for phyſical Uſe, do but impoſe upon the World; for it is ſo rarely met with, that whenever a Branch of an *Oak-tree* hath any of theſe Plants growing upon it, it is cut off, and preſerved by the Curious in their Collections of Natural Curioſities; and of theſe there are but few to be ſeen in *England*.

As to what ſome Perſons have aſſerted of the Manner how it is propagated, from Tree to Tree, by the *Miſleto-Thruſhes*, who eat the Berries, and void the Seed in their Dung, upon the Branches of Trees, whereby the Seeds are ſtuck thereon, and take Root into the Bark, and produce freſh Plants, I can by no means agree to; ſince if it were only this way propagated, it would always be found upon the upper Part or the Sides of ſuch Branches, upon which the Dung can only be ſuppos'd to lodge; whereas it is often found upon the under Side of Branches, where it is almoſt impoſſible for theſe Birds to caſt their Dung; beſides, I believe the Stomachs of theſe Birds are too powerful Digeſters to ſuffer any Seeds to paſs intire through the Inteſtines. But I ſhall leave this to ſuch who have Leiſure to make Obſervations in ſuch Places where this Plant abounds, and ſhall add only a ſhort Account of the Method uſed to make Birdlime, which may not be improper to inſert in this Place for the Satisfaction of the Curious.

The *Italians* make their Birdlime of the Berries of *Miſleto*, heated and mixed with Oil, as that made of *Holly-Bark*; and to make it bear the Water, they add *Turpentine*.

That which is commonly uſed with us, is made of the Bark of *Holly*; which they boil for ten or twelve Hours: and when the green Coat is ſeparated from the other, they cover it up for a Fortnight in a moiſt Place, pounded into a tough Paſte, that no Fibres of the Wood be left; then they waſh it in a running Stream till no Motes appear, and put it up to ferment for four or five Days, and ſcum it as often as any thing ariſes, and then lay it up for Uſe. When they uſe it, they incorporate with it a third Part of that Oil over the Fire.

The Birdlime that is brought from *Damaſcus* is ſuppos'd to be made of *Sebeſtens*, their Kernels being frequently found in it; but this will not endure either Froſt or Wet.

The Birdlime brought from *Spain* is of an ill Smell.

The Bark of our *Lantone* or *Way-faring Shrub*, as it is ſaid, will make Birdlime as good as the beſt.

VISNAGA, *Spaniſh* Picktooth.

The *Characters* are;

It is an umbelliferous Plant, with a roſe-ſhaped Flower, conſiſting of ſeveral Petals, which reſt on the Empalement; which afterwards becomes the Fruit, compoſed of two oblong furrowed Seeds. To theſe Notes muſt be added, The Leaves are finely divided like Fennel; and when the Flowers fall off, the Umbel contracts together.

The *Species* are;

1. VISNAGA *ſeu Gingidium. Mor. Umb.* Common Spaniſh Picktooth.
2. VISNAGA *ſeu Gingidium Montis Libani. Munt. Plant.* Greater Toothpick of *Mount Libanus.*

The firſt Sort grows plentifully in the South of *France*, as alſo in *Spain* and *Italy*. The *Spaniards* make uſe of the Footſtalks of the Umbel for Toothpicks, from whence it obtained this Name. This Plant is preſerved in the Gardens of ſome curious Perſons, for the ſake of Variety. It is an annual Plant, and periſhes ſoon after the Seeds are ripe. The Seeds of this Plant ſhould be ſown early in the *Autumn*, that the Plants may obtain Strength before the Froſt. Theſe will endure the Cold of our *Winters* extremely well, provided the Seeds are ſown on a dry Soil; for theſe Plants do not bear tranſplanting very well: therefore the Seeds ſhould be ſown where the Plants are deſigned to remain. In the *Spring* the Plants ſhould be thinned where they come up too thick, leaving them about ſix or eight Inches aſunder; and if they are afterward kept clear from Weeds, it is all the Culture theſe Plants require. In *June* they will flower, and their Seeds will ripen in *Auguſt*.

The ſecond Sort is leſs common in *England* than the firſt: this is found on *Mount Libanus*, and in ſeveral other mountainous Places in the Eaſt Country. The Umbels of this Sort are much larger than of the former, and the Leaves of the Plant are not ſo finely cut. The Seeds of this Sort have been often brought into *England*, from which I have raiſed the Plants, which have grown very well the former Part of the Seaſon; but they have always decayed ſoon after *Midſummer*, ſo that I never could preſerve any of them to flower.

VITEX; [ſo call'd of *vieo*, *Lat.* to *bend*, becauſe its Branches are very flexible: It is alſo call'd *Agnus Caſtus*, becauſe it is believ'd to allay Luſt, for which the *Monks* were wont to uſe it in their Cloyſters; but by the Taſte and Smell, it ſhould rather be a Provocative: It is alſo call'd *Salix Americana*, becauſe its Leaves reſemble thoſe of a Willow] Agnus Caſtus, *or the* Chaſte-Tree.

The *Characters* are;

It hath a Flower conſiſting of one Leaf, which appears as if it had two Lips, the Fore-part is tubuloſe; from whoſe Flower-cup riſes the Pointal, which afterwards becomes an almoſt-ſpherical Fruit, which is divided into four Cells, in which are contain'd oblong Seeds; to which may be added, the Leaves are digitated (or finger'd) like thoſe of Hemp.

The *Species* are;

1. VITEX *foliis anguſtioribus, cannabis modo diſpoſitis. C. B. P.* The Chaſte-Tree, with narrow Leaves.
2. VITEX *latiore folio. C. B. P.* The Chaſte-Tree, with broad ſerrated Leaves.
3. VITEX *ſive Agnus, flore albido. H. R. Par.* The Chaſte-Tree, with whitiſh Flowers.
4. VITEX *ſive Agnus minor, foliis anguſtiſſimis. H. R. Par.* The leſſer Chaſte-Tree, with very narrow Leaves.

The firſt of theſe Plants is pretty common in moſt *Engliſh* Gardens, where a Variety of hardy Trees are preſerv'd; but the other Sorts are leſs common, and only in ſome curious Gardens at preſent. Theſe Plants are all very hardy, and may be propagated by planting their Cuttings early in the *Spring*, before they ſhoot; they require a freſh, light Soil, and muſt be frequently refreſh'd with Water, until they have taken Root; after which they muſt be carefully clear'd from Weeds, during the *Summer* Seaſon; and if the *Winter* proves ſevere, you muſt lay a little Mulch upon the Surface of the Ground between the Plants, to prevent the Froſt from penetrating to their Roots, which would injure them while they are young: Toward the Middle of *March*, if the Seaſon be favourable, you ſhould tranſplant them either into the Places where they are deſign'd to remain, or into a Nurſery for two or three Years, to get Strength; where they muſt be prun'd up, in order to form them into regular Plants, otherwiſe they are very ſubject to ſhoot out their Branches in a ſtraggling manner.

If theſe Plants are plac'd in a warm Situation, and have a kindly light Soil, they will grow to be eight or ten Feet high, and produce their Spikes of Flowers at the Extremity of every ſtrong Shoot in *Autumn*; which altho' of no great Beauty, yet coming late in the Year, and having an odd Appearance, together with the Variety of their Leaves, renders them worthy of a Place in ſmall Wilderneſs Quarters amongſt other Shrubs of the ſame Growth.

They may alſo be propagated by laying down their Branches in the *Spring* of the Year, (in doing of which you muſt be very careful not to break them, for their Shoots are extremely brittle, and very ſubject to ſplit off with the leaſt Violence:) Theſe will take Root in one Year, provided they are water'd in very dry Weather; and may then be tranſplanted out, and managed as was directed for thoſe Plants rais'd from Cuttings.

VITIS; [ſo called from *vieo*, Lat. to *bend* or *bind*, becauſe its Claſpers take hold of the neighbouring Plants] The Vine.

The *Characters* are;

The Flower conſiſts of many Leaves, which are placed in a circular Order, and expand in form of a Roſe; the Ovary, which is ſituated in the Bottom of the Flower, afterwards becomes an oval or round Fruit, which is very full of Juice, and contains many ſmall Stones in each. To which ſhould be added, that the Tree is climbing, ſending forth Claſpers at the Joints, by which it faſtens itſelf to whatever Plant ſtands near it, and the Fruit is produced in Bunches.

The *Species* are;

1. VITIS *ſylveſtris Labruſca. C. B. P.* The Wild Vine, *commonly called* the Claret Grape. This Sort of Grape is pretty well known in *England*; it has a Berry of a middling Size, of a deep black Colour, covered over with a Bloom like a Plum, which may be wiped off; the Juice ſtains of a deep red Colour, and before it is quite dead-ripe, is of an auſtere Taſte; the Bunches are pretty large, but ſhort, having commonly two Side-bunches, or Shoulders, on the upper Part of the Bunch: The Leaves of this Vine are jagged, and change to a deep red Colour before they fall off.
2. VITIS *præcox columellæ. H. R. Par.* This is called in *England* the *July Grape*, but in *France*, *Morillon* and *Vigne haſtive*. This is the earlieſt Grape at preſent known in *England*, for which it is chiefly preſerved, for it is not much eſteemed for its Goodneſs: The Skin is thick, the Juice but very indifferent, and the Berries do commonly grow very thin upon the Bunches. Theſe are of a middle Size, and of a dark, muddy, red Colour.
3. VITIS *Corinthiaca ſive Apyrina. J. B.* The Corinth Grape, *vulgarly called* the Currant Grape: Is an early Ripener, the Berry is ſmall and ſlender, the Juice very ſweet, and hath very little Stone. Of this Kind there are two or three different Colours, as red, black, and tawney. This is the Sort which is brought from the Iſlands near the *Morea*, by the Name of Currants, and ſold by the Grocers of *London*, to put into Puddings, &c.
4. VITIS *laciniatis foliis. Cornut.* The Parſley-leav'd Grape, *vulgo*. This Sort was originally brought from *Canada*, where it grows wild in the Woods; and is preſerved in the Gardens of the Curious, for the Variety of its fine jagged Leaves. This is a pretty large white Grape, and has a ſweet Juice, but not very vinous; the Berries are very apt to grow thin upon the Bunches, unleſs the Vine is pruned ſhort, and left but thin with Wood.
5. VITIS *ſubhirſuta. C. B. P.* The Morillon Taconne, *or* Munier, *i. e.* the Miller's Grape; this is called the *Burgundy* in *England*. The Leaves of this Sort are very much powder'd with white, eſpecially in the *Spring*, when they firſt come out, from whence it had the Name of *Miller's Grape*. It produces middle-ſiz'd black Grapes, which grow cloſe upon the Bunches, and are generally ſhort and thick. This is an excellent Bearer, and a hardy Sort.
6. VITIS *præcox columellæ, acinis dulcibus nigricantibus.* The black Morillon. This is called in *Burgundy*, *Pineau*, and at *Orleans*, *Auverna*. It is a very ſweet Grape, of a middle Size, ſomewhat oval, and of a fine black Colour; the Bunches are ſomewhat longer than thoſe of the former. This makes very good Wine.

7. Vitis *uva perampla, acinis albidis, dulcibus durioribus. Tourn.* The Chaſſelas blanc, Bar-ſur-Aube, White Chaſſelas, *or* Royal Muſcadine. This is a large white Grape, and grows cloſe upon the Bunches, which are alſo very large, and have commonly two ſmall Side-bunches or Shoulders, produced from the upper Part of the Bunch; the Berries, when full ripe, if well expoſed to the Sun, change to a pale amber Colour, the Juice is very rich, and the Fruit is commonly ripe early in *September*.

8. Vitis *uva perampla, acinis dulcibus nigricantibus. Tourn.* The Chaſſelas Noir, *i. e.* the black Chaſſelas. This is very often called the *Black Muſcadine.* The Berries of this are as large as thoſe of the former, the Bunches are commonly larger, and are ſomewhat later ripe; the Juice is very rich. If well expoſed, they bear well, and are ripe toward the End of *September*.

9. Vitis *uva perampla, acinis dulcibus rubentibus. Tourn.* The red Chaſſelas. This is alſo called the *Red Muſcadine.* The Berries of this Sort are a little larger than thoſe of the former, and grow much thinner upon the Bunches, are of a faint red Colour, and the Juice is very ſweet, but later ripe, upon which account it is not ſo valuable in *England*.

10. Vitis *uva perampla, acinis ovatis albidis. Tourn.* The Burdelais, *vulgarly called* Burlake. The Berries of this Kind are very large, of an oval Shape, and grow pretty cloſe on the Bunches, which are ſometimes of a prodigious Size. I have ſeen a Bunch of theſe Grapes which has weighed five Pounds. But they never ripen in this Country, ſo that they are fit for nothing, except *Verjuice*, or to make Tarts.

11. Vitis *acinis albis dulciſſimis, Vitis Apiana. C. B. P. Garidel.* The Muſcat, *or* White Frontiniac. The Berries of this Kind are large, and grow extremely cloſe upon the Bunches, which are very long, and have commonly two Shoulders to them: The Fruit, when ripe, has a rich, muſky Flavour; but it is commonly very late in the *Autumn* before they ripen, and the Berries being ſo very cloſe upon the Bunches, do detain the Moiſture in their Middles, ſo that they commonly periſh· To prevent which, ſome very curious Perſons look over their Vines ſoon after the Grapes are formed, and with a Pair of Sciſſars cut out all the ſmall ones, ſo as to leave the others at a moderate Diſtance, whereby the Sun and Air is eaſily admitted, which diſſipates the Moiſture, and prevents their periſhing, This Sort is a great Bearer.

12. Vitis *acinis rubris, nigricantibus dulciſſimus. Garidel.* The Muſcat Rouge, *or* Red Frontiniac. The Berries of this Kind are of the Size of the former, but grow much thinner on the Bunches; it is higher flavour'd, and when thorough ripe, is the richeſt Grape yet known. But this muſt have a very dry Soil, and a South-Eaſt Aſpect, otherwiſe it ſeldom ripens well in *England*.

13. Vitis *acinis nigricantibus dulciſſimis.* The Black Frontiniac. The Berries of this Kind are leſs than the two former, but are not ſo high-flavour'd; their Juice is ſweet, and they are earlier ripe. This is a good Bearer, but the Grapes upon the ſame Bunch do ſeldom ripen at the ſame Time, ſo that they can't be gather'd in full Bunches, but muſt be pick'd off ſingly as they ripen.

14. Vitis *Damaſcena. H. R. Par.* The Damaſk Grape. The Berries of this Kind are very large, black, and of an oval Form; the Bunches are very large, and the Vine produces vigorous Shoots. This ripens late in *England*.

15. Vitis *præcox, acino rotundo, albido dulci.* The White Sweet-water. The Berries of this Kind are large and white, the Skins are very thin, and the Juice is ſweet: this is very early ripe, but the Berries are apt to be thin upon the Bunches; for it is one of the tendereſt Sorts, when in flower, that I have yet ſeen; ſo that if there happens bad Weather at that Seaſon, they are very ſubject to blight, and being ſo uncertain in bearing, has render'd it leſs eſteemed than it was formerly.

16. Vitis *præcox, acino nigro, dulci & rotundo.* The Black Sweet-water. This is a leſs Grape than the former, it is of a fine black Colour, and grows pretty cloſe upon the Bunches; its Juice is ſweet, and it is early ripe.

17. Vitis *alba dulcis. J. B.* The White Muſcadine. The Berries of this Kind are large, of a white Colour, and the Juice is very ſweet; the Bunches are long, and it is early ripe.

18. Vitis *Allobrogica. Plinii Car. Steph. Præd. Ruſt.* The Raiſin Grape. This is a large oval Grape of a blackiſh Colour, when ripe; the Bunches are very large, and make a fine Appearance, but never ripen well in *England.* I have known ſome Perſons who had a great Quantity of this Sort of Grape, which they commonly cut in the Middle of *October*, with pretty long Stalks to the Bunches, and hung them on Strings, in Rows in their Kitchen, at ſuch a Diſtance as not to touch each other; and about *Chriſtmas*, theſe Grapes would be ſo ripened by the Warmth of the Room, as to eat extremely well.

19. Vitis *acino rubro, duriori ſapore dulci. Garidel.* The Greek Grape. This is a middle-ſiz'd Grape, of a deep red Colour, the Skin is very tough, and the Stones are ſmall; this is by many People called the *Brick Grape.* In a kindly Seaſon, when theſe Grapes ripen well, they make excellent Wine; but it muſt have a good Wall, otherwiſe it will not ripen in *England*.

20. Vitis *pergulana uva perampla, acino oblongo duro, majori & ſubviridi. Garidel.* The Pearl Grape, called in *Provence*, Pendoulau, *or* Rin de Ponſo. This is a large oblong Grape, of a greeniſh white Colour, the Juice has a Mixture of ſweet and ſour, and it is late ripe.

21. Vitis *uva perampla, acinis nigricantibus majoribus.* The St. Peter's Grape, *or* Heſperian. The Berries of this Sort are very large, round, and of a deep black Colour when ripe; the Bunches are very large, and have two Shoulders to them; the Juice is very rich, and a little ting'd with red; the Leaves of this Sort are remarkably jagged, ſo as to be known when there is no Fruit upon the Vines; it is late ripe. I believe this is the ſame Sort which the *French* call *Gros Noir d' Eſpagne*, i. e. *Great Black Spaniſh*.

22. *La Malvoiſe*, i. e. the *Malmſey Grape*; is a middle-ſiz'd Fruit, of a muddy red Colour, its Juice is very rich and ſoft, the Bunches are large, and it is a great Bearer; this ripens toward the latter End of *September*.

23. *Malvoiſe Muſquée*, i. e. the *Malmſey Muſcadine*. This is a middle-ſiz'd Grape, rather long than round, of a rich, muſky Flavour when ripe. This is one of the Sorts of Grapes from which the *Madeira* Wine is made. It ripens late in *England*.

24. The *Red Hamburgh Grape.* The Berries of this Kind are large, and of a reddiſh Colour, covered with a Flue; the Bunches are large, and it is a good Bearer. This ripens toward the End of *September*, and is a fine Grape. It was brought into *England* by Mr. *Warner* of *Rotherhith*, who hath ſupply'd many curious Perſons with it.

25. The *Black Hamburgh*, or *Warner Grape.* This has a middle-ſiz'd Berry, rather long than round, of a fine black Colour when ripe; the Juice is very rich, ſomewhat inclining to a muſky Flavour. This ripens about the Middle of *September*. It was brought into *England* by Mr. *Warner*, with the former.

26. *Raiſin Swiſſe*, i. e. the *Switzerland Grape.* This is preſerved only as a Curioſity; the Fruit of this Kind are ſtriped with white and black, and ſometimes divided into Quarters of thoſe Colours, and many times half the Bunch is white, and the other half black, and ſome entire Bunches are white, and others black, ſo that it appears as if two Kinds had been grafted on the ſame Root. The Fruit is good for little, but Shew, therefore one Plant of this Kind is enough in a Garden.

All the Sorts of *Vines* are propagated either from Layers or Cuttings, the former of which is greatly practiſed in *England*, but the latter is what I would recommend, as being much preferable to the other. For the Roots of *Vines* do not grow ſtrong and woody, as in moſt Sorts of Trees, but are long, ſlender and pliant; ſo that when they are taken out of the Ground, they ſeldom ſtrike out again, but ſhrivel and dry, ſo that they rather retard than help the Plants in their Growth, by preventing the new Fibres from puſhing out; for which Reaſon I had rather plant a good Cutting than a rooted Plant, provided it be well choſen, and there is leſs Danger of its not growing.

But as there are few Perſons who make Choice of proper Cuttings, or at leaſt that do form their Cuttings rightly, in *England*, ſo it will be proper to give Directions for this Work in the firſt Place, before I proceed. You ſhould always make Choice of ſuch Shoots as are ſtrong and well ripen'd of the laſt Year's Growth; theſe ſhould be cut from the old *Vine*, juſt below the Place where they were produced, taking a Knot of the Two-years Wood, which ſhould be pruned ſmooth; then you ſhould cut off the upper Part of the Shoot, ſo as to leave the Cutting about ſixteen Inches long: Now, in making the Cuttings after this Manner, there can be but one taken from each Shoot; whereas moſt Perſons cut them into Lengths of about a Foot, and plant them all, which is very wrong; for the upper Parts of the Shoots are never ſo well ripened as the lower Part which was produced early in the *Spring*; ſo that if they do take Root, they never make ſo good Plants, for the Wood of thoſe Cuttings being ſpungy and ſoft, admits the Moiſture too freely, whereby the Plants will be luxuriant in Growth, but never ſo fruitful as ſuch whoſe Wood is cloſer and more compact.

When the Cuttings are thus prepared, they ſhould be placed with their lower Part into the Ground, in a dry Place, laying ſome Litter about their upper Parts, to prevent them from drying; in this Situation they may remain until the Beginning of *April* (which is the beſt Time for planting them) when you ſhould take them out, and waſh them from the Filth they have contracted; and if you find them very dry, you ſhould let them ſtand with their lower Parts in Water, ſix or eight Hours, which will diſtend their Veſſels, and diſpoſe them for taking Root. Then ſet about preparing the Ground where the Plants are deſigned to remain, (whether againſt Walls or for Standards) for they ſhould not be removed again. But as I intend hereafter to treat in particular about the planting and Management of *Vineyards*, ſo in this Place I ſhall confine myſelf only to ſuch as are planted either againſt Walls or Pales, for eating.

In preparing the Ground, you ſhould conſider the Nature of the Soil, which, if ſtrong and inclinable to Wet, is by no Means proper for Grapes; but where it thus happens, you ſhould open a Trench againſt the Wall, which ſhould be filled with Lime-rubbiſh, the better to drain off the Moiſture, then raiſe the Border with freſh light Earth about a Foot thick, ſo that it may be at leaſt a Foot above the Level of the Ground; then you ſhould open the Holes about ſix Feet diſtance from each other, putting one good ſtrong Cutting into each Hole, which ſhould be laid a little ſloping, that their Tops may incline to the Wall; but muſt be put in ſo deep, that the uppermoſt Eye may be level with the Surface of the Ground: For when there are two or three Eyes left above Ground, as is the common Method uſed by the *Engliſh* Gardeners, they do all attempt to ſhoot, ſo that the Strength of the Cuttings is divided to nouriſh ſo many Shoots, whereas on the contrary, it is all employ'd on one ſingle Shoot, which conſequently will be much ſtronger; beſides, the Sun and Air is apt to dry that Part of the Shoots which remains above Ground, and ſo often prevents their Buds from ſhooting.

Then having placed in the Cutting, you ſhould fill up the Hole, gently preſſing down the Earth with your Foot, and raiſe a little Hill juſt upon the Top of the Cutting, to cover the upper Eye quite over, which will prevent it from drying. This being done, there is nothing more neceſſary, but to keep the Ground clear from Weeds, until the Cuttings begin to ſhoot, at which Time you ſhould look over them carefully, to rub off any dangling Shoots, if ſuch are produced, and faſten the main Shoot to the Wall; which ſhould be conſtantly faſtened up, as it is extended in Length, to prevent its breaking or hanging down. You muſt continue alſo, during the *Summer* Seaſon, conſtantly rubbing off all lateral Shoots which are produced, leaving only the firſt main Shoot; and be ſure to keep the Ground conſtantly clear from Weeds, which, if ſuffer'd to grow, will exhauſt the Goodneſs of the Soil, and ſtarve the Cuttings.

The *Michaelmas* following, if your Cuttings have produced ſtrong Shoots, you ſhould prune them down to two Eyes, (which, tho' by ſome People may be thought too ſhort, yet I am ſatisfied, from ſeveral Experiments, to be the beſt Method): The Reaſon for adviſing the pruning the *Vines* at this Seaſon, rather than deferring it till *Spring*, is, becauſe the tender Parts of thoſe young Shoots, if left on, are ſubject to decay in *Winter*, and imbibe ſome noxious Matter from the Air, which greatly weakens their Roots; ſo that if they are cut off early in *Autumn*, the Wounds will heal over before the bad Weather, and thereby the Roots will be greatly ſtrengthened.

In the *Spring*, after the cold Weather is paſt, you muſt gently dig up the Borders, to looſen the Earth; but you muſt be very careful in the doing of this, not to injure the Roots of your *Vines*; you ſhould alſo raiſe the Earth up to the Stems of the Plants, ſo as to cover the old Wood, but not ſo deep as to cover either of the Eyes of the laſt Year's Wood. After this they will require no farther Care until they begin to ſhoot, when you ſhould look over them carefully, to rub off all weak dangling Shoots, leaving no more than the two Shoots, which are produced from the two Eyes of the laſt Year's Wood, which ſhould be faſtened to the Wall; and ſo from this, until the *Vines* have done ſhooting, you ſhould look them over, once in three Weeks, to rub off all lateral Shoots as they are produced, and to faſten the two main Shoots to the Wall, as they are extended in Length, which muſt not be ſhortened before the Middle of *July*, when it will be proper to nip off their Tops, which will ſtrengthen the lower Eyes. And during the *Summer* Seaſon, you muſt conſtantly keep the Ground clear from Weeds; nor ſhould you permit any Sort of Plants to grow near the *Vines*, which would not only rob them of Nouriſhment, but ſhade the lower Parts of the Shoots, and thereby prevent their ripening; which will not only cauſe their Wood to be ſpungy and luxuriant, but render it leſs fruitful.

At *Michaelmas* you ſhould prune theſe again, leaving three Buds to each of the Shoots provided they are ſtrong, otherwiſe it is better to ſhorten them down to two Eyes, (for it is very wrong Practice to leave much Wood upon young *Vines*, or to lay their Shoots in too long, which greatly weakens the Roots) then you ſhould faſten them to the Wall, drawing each of them out horizontally from the Stem; then, in the *Spring*, dig the Borders as before.

The third Seaſon you muſt go over the *Vines* again, ſo ſoon as they begin to ſhoot, rubbing off all Danglers, as before, and training in the leading Shoots (which this Seaſon may be ſuppoſed to be two from each Shoot of the laſt Year's Wood; but if they attempt to produce two Shoots from one Eye, the weakeſt of them muſt be rubbed off, for there ſhould never be more than one allowed to come out of an Eye). If any of them produces Fruit, as many times they will the third Year, you ſhould not ſtop them, (ſo ſoon as is generally practiſed upon the bearing Shoots of old *Vines*) but permit them to ſhoot forward till *Midſummer*, at which Time you may pinch off the Tops of the Shoots, for if this were done too ſoon, it would ſpoil the Buds for the next Year's Wood, which in young *Vines* muſt be carefully preſerved, becauſe there are no Shoots laid in on purpoſe for Wood, as is commonly practis'd on old *Vines*.

During the *Summer* you muſt conſtantly go over your *Vines*, and diſplace all weak, lateral Shoots as they are produced, and carefully keep the Ground clear from Weeds, (as was before directed) that the Shoots may ripen well, which is a material thing to be obſerved in moſt Sorts of Fruit-Trees, but eſpecially in *Vines*; which ſeldom produce any Fruit from immature Branches. Theſe Things being duly obſerved, are all that is neceſſary in the Management of young *Vines*. I ſhall therefore proceed to lay down Rules for the Government of grown *Vines*, which I ſhall do as briefly as poſſible. And,

Firſt, *Vines* do rarely produce any Bearing-Shoots from Wood that is more than one Year old; therefore great Care ſhould be taken to have ſuch Wood in every Part of the Trees; for the Fruit are always produced upon Shoots which come out from the Buds of the laſt Year's Wood, ſo that is always upon the ſame Year's Shoots. The Method commonly practis'd by the Gardeners in *England*, is, to ſhorten the Branches of the former Years Growth, down to three or four Eyes, at the Time of pruning; tho' there are ſome Perſons who leave theſe Shoots four or five Eyes long, and affirm, that by this Practice they obtain a greater Quantity of Fruit: But this is very wrong, ſince it is impoſſible that one Root can nouriſh forty or fifty Bunches of Grapes, ſo well as it can ten or twelve; ſo that what is gotten in Number is loſt in their Magnitude; beſides, the greater Quantity of Fruit there is left on *Vines*, the later they are ripen'd, and their Juice is not ſo rich. And this is well known in the Wine Countries, where there are Laws enacted, to direct the Quantity of Shoots, and the Number of Eyes that thoſe are to have upon each Root, leſt by overbearing them, they not only exhauſt and weaken the Roots, but thereby render the Juice weak, and ſo deſtroy the Reputation of their *Wine*.

Wherefore, the beſt Method is, to leave the Bearing-Shoots about four Eyes in Length, (becauſe the lowermoſt never produce) and three Buds are ſufficient; for each of theſe will produce two or three Bunches; ſo that from each of thoſe Shoots there may be expected ſix or eight Bunches, which is a ſufficient Quantity. Theſe Shoots muſt be laid in about eighteen Inches aſunder; for if they are cloſer, when the Side-Shoots are produced, there will not be Room enough to train them in againſt the Wall, which ſhould always be obſerved; and as their Leaves are very large, ſo the Branches ſhould be left at a proportionable Diſtance, that they may not crowd or ſhade each other.

In Pruning, you ſhould always obſerve to make the Cut juſt above an Eye, ſloping it backward from it, that if it ſhould bleed, the Sap might not flow upon the Bud: And where there is an Opportunity of cutting down ſome young Shoots to two Eyes, in order to produce vigorous Shoots for the next Year's Bearing, it ſhould always be done; becauſe in ſtopping of thoſe Shoots which have Fruit upon them in *May*, it often ſpoils the Eyes for Bearing; and this reſerving of new Wood, is what the *Vignerons* abroad do always practiſe in their Vineyards. The beſt Seaſon for Pruning of *Vines*, is the End of *September* or the Beginning of *October*, for the Reaſons before laid down.

The Latter-end of *April*, or the Beginning of *May*, when the *Vines* begin to ſhoot, you muſt carefully look them over, rubbing off all ſmall Buds which may come from the old Wood, which do not only produce weak dangling Branches; as alſo when two Shoots are produc'd from the ſame Bud, the weakeſt of them ſhould be diſplac'd, which will cauſe the others to be the ſtronger; and the ſooner this is done, the better it is for the *Vines*.

In the Middle of *May*, you muſt go over them again, rubbing off all the dangling Shoots, as before, and at the ſame time you muſt nail up all the ſtrong Branches, ſo that they may not hang from the Wall; for if their Shoots hang down, their Leaves will be turn'd the wrong Way; which when the Shoots are afterwards nail'd upright, will have their back Surface upward; and until the Leaves are turn'd again, and have taken their right Direction, the Fruit will not thrive: So that the not obſerving this Management, will cauſe the *Grapes* to be a Fortnight later before they ripen. Beſides, by ſuffering the Fruit to hang from the Wall, and be ſhaded with the Cloſeneſs of the Branches, it is greatly retarded in its Growth: Therefore, during the growing Seaſon, you ſhould conſtantly look over the *Vines*, diſplacing all dangling Branches and wild Wood, and faſten up the other Shoots regularly to the Wall, as they are extended in Length; and towards the Latter-end of *May*, you ſhould ſtop the Bearing-Branches, which will ſtrengthen the Fruit, provided you always leave three Eyes above the Bunches; for if you ſtop them too ſoon, it will injure the Fruit, by taking away that Part of the Branch which is neceſſary to attract the Nouriſhment to the Fruit, as alſo to perſpire off the Crudities of the Sap, which is not proper for the Fruit to receive.

But although I recommend the ſtopping thoſe Shoots which have Fruit at this Seaſon, yet you ſhould by no means ſtop thoſe which are intended for bearing the next Year, before the Beginning of *July*, leſt by ſtopping them too ſoon, you cauſe the Eyes to ſhoot out ſtrong lateral Branches, whereby they will be greatly injured. Theſe therefore ſhould be train'd upright againſt the Wall until that time; when their Tops may be nipp'd off, to give Strength to the lower Buds.

During the *Summer* Seaſon, you ſhould be very careful to rub off all dangling Branches, and train up the Shoots regularly to the Wall, which will greatly accelerate the Growth of the Fruit; and alſo admit the Sun and Air to them, which is abſolutely neceſſary to ripen, and give the Fruit a rich Flavour; but you muſt never diveſt the Branches of their Leaves, as is the Practice of ſome Perſons; for altho' the admitting of the Sun is neceſſary to ripen them, yet if they are too much expos'd thereto, their Skins will be tough, and they will rarely ripen; Beſides, the Leaves being abſolutely neceſſary to nouriſh the Fruit, by taking them off, the Fruit is ſtarv'd, and ſeldom comes to any Size, as I have ſeveral times obſerv'd; therefore a great Regard ſhould be had to the *Summer* Management of the *Vines*, where Perſons are deſirous to have their Fruit excellent and duly ripen'd.

When the Fruit are all gather'd, you ſhould prune the *Vines*, whereby the Litter of their Leaves will be intirely remov'd at once, and the Fruit will be the forwarder the ſucceeding Year, as has been before obſerv'd.

Having thus treated of the Management of *Vines* againſt Walls, &c. I come next to the Culture of ſuch as are planted in Vineyards; but as the Number of thoſe in *England* is ſmall, and the Experience of them not very great, ſo I ſhall firſt ſubjoin an Account of their Planting and Managing their Vineyards in *Italy* and *France*, and then ſhall add ſome Obſervations and Experiments of my own. And firſt, I ſhall inſert a curious Account of the Method the *Italians* follow in planting their Vineyards, and making their Wine, which I receiv'd from an ingenious Correſpondent in that Country, who hath ſome Vineyards of his own, and hath been very exact in his Obſervations upon the different Methods now practis'd by the *Italians* in their Vineyards; which is as follows.

The Method of managing their Vineyards, *and making their* Vines *in* Italy.

1. As to the Soil; next to that of *Chianti*, which is in a manner all rocky, they prefer that of the hilly Parts of this Country, which has a warm, ſtony Bottom, with a loamy Superficies; and next to that, ſuch as has a lime ſtone or chalky Bottom, with a reaſonable deep Surface of any good Earth; but in the Plains, where the Wines are nothing comparable to thoſe of the Hills and Mountains, they are forc'd to content themſelves with any tolerably good Sort of Ground, that is neither ſandy nor light to Exceſs, nor too clayey or binding, though a pretty ſtiff Marle does well enough.

2. As to its Expoſure, they chuſe one that is due South, or that inclines to the Weſt rather than to the Eaſt: And in the Plains, they are oblig'd to be contented, as will be here related, with a North one for part of their Vineyards; which they fence, however, if not naturally cover'd with ſome Wood or adjacent Hill, with either a good Hedge or a Stone-wall, againſt the Northern Blaſts.

3. The Manner of preparing the Ground for Planting, differs according to the Situation of it; being perform'd one Way when on Mountains; another when on more moderate Hills; and a different, in ſome reſpects, to that when on a Plain or Level.

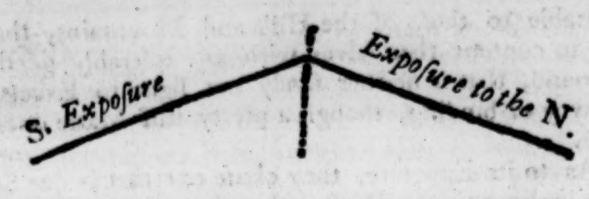
In thoſe Plains which are very mountainous and rocky; as alſo the Hills, where the Bottom of Stone is found near the Superficies, and is hard, they, with the Help of proper Inſtruments, or elſe with Gunpowder, make a Trench of four Feet and a half deep, and three and an half wide, drawing it from Eaſt to Weſt, (and tho' it may be near, yet always ſomewhat under the Summit or Top of the Mountain, to be cover'd from the North Wind thereby;) and with part of the Stones which they raiſe out of the Foundation, they make a dry Wall (*i. e.* without Mortar) juſt below the Trench; about twelve Feet below this they make a ſecond Trench in like manner, levelling the Ground between the Trenches, as well as they can, with Mattocks, Crows of Iron, &c. and ſo proceed till they have finiſh'd the whole Ground they intend to plant.

The Uſe of thoſe little Walls is to keep the little Earth there is from being waſh'd away by impetuous Rains: For the carrying off of which, they make proper Channels at convenient Places; ſo that the whole Plantation, at ſome Diſtance, reſembles a regular magnificent Pair of Stairs. In which Trenches, at about three Feet diſtance one from the other, they plant the Cuttings of *Vines*, ſomewhat ſlanting, about the Depth of two and a half or near three Feet: Which being dreſs'd as hereafter related, and when they come to their Bearing, being kept of an equal Height, make a moſt agreeable Proſpect.

When the Ground is hilly, but not very mountainous, they dig a Trench about four Feet and a half deep, and three and a half wide; and then having thrown the Earth to the Northward, they make a ſecond with the Earth whereof they fill the firſt, and ſo on, one under and cloſe to the other, till they have finiſh'd the Ground they would plant, the laſt ſerving for a Ditch to carry the Water off: Into which at proper Diſtances, they alſo make little Ditches to convey the Water; and having ſo done, and thrown the Earth taken out of the firſt Trench on to the trench'd Ground, and levell'd it ſo as to give it an even proper Declivity, they plant it with the Cuttings of *Vines* in Quadrangles or other Manner, at the Diſtance of above five Feet and a half or more, as they think moſt proper for their Ground: If ſtony, in the manner before related, as practis'd in the Mountains; but if not, then as they do it in the Plains, as will be hereafter deſcrib'd.

When the Vineyard is to be made on a Plain or an exact Level, having ſtak'd the Part out they deſign for Walks, and laid out the Diviſions they intend for *Vines*, their next Care is, that each of them have a proper Declivity, and that there be good Drains to carry the Water off; in order to which, they make the firſt trench exactly in the Middle of the Diviſion, extending from Eaſt to Weſt, of the Depth of four Feet and a half, and near four Feet in Breadth, throwing the Earth taken out of it Northward; when laying at the Bottom Stones, Bruſhwood, Bones, or almoſt any Sort of Rubbiſh to raiſe and drain it, they proceed to the ſecond Trench; with the Earth of which they fill the firſt, and ſo on till they have finiſh'd as far as the ſecond Diviſion extends Southward, laying at the Bottom of every Trench ſuch Rubbiſh as they can get; and then removing the Earth taken out of the firſt Trench over to the South-ſide already trench'd, they proceed to trench in the ſame manner on the North-ſide, as far as the Diviſion extends; when in the laſt Trench there will naturally remain a Ditch (the Side of which ſome very curious People wall with a dry Wall) to carry off the Water, whence they take Care to make proper Drains to carry it away.

This being done, they proceed to level this Piece of Ground, giving each Side thereof its proper Declivity, ſo that it ſomewhat reſembles a Roof that is not ſteep, or, as they here term it, a Mule's Back, bearing the following Figure: And thus they do to preſerve the *Vines* they plant the

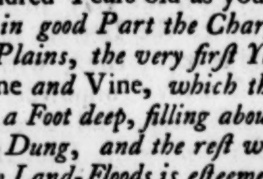


the longer, and to make them render better Wines, whilſt thoſe that are planted on the Flat, and on the Borders of Ditches, where they are ſupported by a ſort of *Poplar-Trees*, and ſerve for the Diviſion of the *Corn-Fields*, though the *Vines* grow to a great Thickneſs, and produce much Fruit, yet they render a Wine that is good for little, and will not laſt above thirty-five or forty Years; whereas what is ſo planted, being tolerably well looked after, holds good for one hundred and forty, or one hundred and fifty, and in *Chianti* they will laſt above three hundred Years, they there accounting thoſe of one hundred Years old as young *Vines*.

N. B. *To defray in good Part the Charge of this expenſive Culture, thoſe in the Plains, the very firſt Year, ſow a Hole of* Melons *between* Vine *and* Vine, *which they make about ten Inches diameter, and a Foot deep, filling about three-fourths of it with good macerated Dung, and the reſt with fine good Earth, (of which that left by Land-Floods is eſteemed the beſt) in which they put about fifteen or twenty Seeds; which being come up, before they put out the domeſtick Leaf, they nip the Tops of all but two or at moſt three of the ſtrongeſt Plants, which they leave to bear Fruit, and order accordingly. After which they plant* Cauliflowers, *or* Brocoli *of* Cauliflowers; *and this they alſo do in the Hills ſo trenched; but in the Mountains* Melons *do not well in the Trenches; but* Beet-Root *is often produc'd, and* Cauliflowers.

The Ground being ſo ordered, where the Vineyard is in a Plain, or on the Hills, they proceed to mark it out with Lines, according to the Diſtances they would plant at, endeavouring to do it in Rows about three Feet *Vine* from *Vine*, and about four, or four and a half, from Row to Row, but for the moſt part in a Quadrangular manner, at the Diſtance of about four Feet one from the other, drawing Lines lengthways and athwart: In the Croſs they plant the Cut of a *Vine* in the following manner:

Having an iron Crow of an Inch or better diameter, a little pointed at the End, they therewith make an Hole directly down about three Feet and a half deep; then being provided with an Inſtrument, they call a *Crucciolo*, having an Handle of Wood like that of a large Augar, and the Body of Iron four Feet long, and better than half an Ich in diameter, at the End of which there is a Nich ſomething like an Half-moon, making this Figure, they, after twiſting the End of the Cutting, put it therein, and ſo force it down to the Bottom of the Hole, where they then leave it, and afterwards fill up the Vacancy with fine ſifted Earth or Sand, obſerving to tread the Earth cloſe to the Plants, which otherwiſe (unleſs it be ſtiff Land) is often inclinable to be looſe and dry, eſpecially if Rain does not ſoon follow their Planting; and it is incredible how many *Vines* three Perſons can in this manner plant in one Day, *viz.* upwards of Two thouſand.



As the Cuttings are of a good Length, there generally remain about two Feet or better of them above the Ground, when planted, and ſometimes more. When, as it frequently happens, they find the Earth ſhallow, ſo that in the trenching they arrive at prime Rock, or a cold bleakiſh Clay, at the Depth of about three Feet, and therefore they trench not lower, they plant the Depth of two and a quarter, or two and an half Feet; ſhallower than which they never plant, and even then, if the Bottom be Clay, they will do but little; and if rocky, are apt to ſuffer in the *Summer* by dry hot Weather, (tho' if once they ſtrike their Roots in the Rock they do well enough) and yield the beſt Wine that is made in the Plains, which, however, tho' planted with the ſame Sort of *Vines* as thoſe of the Mountains, and even of Cuttings brought from thence, never produce near ſo good Wines as thoſe that grow there, notwithſtanding the *Grapes* ripen three Weeks, if not a Month, ſooner.

N. B. *This Tillage and Plantation is performed at any time between* November *and* March, *in dry, but not froſty Weather, ſince then the frozen Earth in working being naturally thrown into the Bottom of the Trench, where the* Vines *are to make their principal Roots, it retains ſuch a Frigidity, that they will thrive but badly in it; which will be the Caſe alſo if the Ground be laboured too wet: wherefore this Trenching or thorough Tillage is generally performed in* February, *after the Severity of the Froſts is over, and may be planted at any time between that and* April; *whilſt as for the Cuttings, they are obſerved to be beſt when planted as ſoon as cut off in the dreſſing: but if that Conveniency is not to be had, they may be brought from any reaſonable Diſtance, their Cut-Ends only being tyed up, and covered from the Air with Moſs, Straw, or the like; or if from a greater, with ſome Earth about them, and may be kept, burying the Cut-Ends in the Ground, till ſuch time as they can be us'd: But juſt before this is done, it is proper to put them in Water for twelve Hours or more, ſince that will influence them to ſtrike Root the better.*

It is not of much Importance, that the Cuttings be from the beſt ſort of Grapes, *though that is beſt, if eaſily to be had, but may be from any* Vines *in the Neighbourhood that thrive well; for afterwards, when they come to their Bearing, you may with little Trouble, ingraft them with Cuttings from* Vines *of the Sorts you deſire; and theſe will bear ſome Fruit the very Year they are ingrafted, and moſt abundantly the next; beſides, that the Foot of the* Vine *or* Stock *will receive Benefit by this Operation.*

5. The Plantation having been made in the manner before related, the firſt Culture of it is performed different Ways; which, as one of them has been practiſed but of late Years, they may be termed the Old and the Modern.

According to the *Old Way*, about a Month after the Planting, when they begin to ſhoot, they cut off the Tops of the Plants juſt above the ſecond Eye that is above the Ground, and ſo let them remain, and ſhoot out at Pleaſure, only after the *Melons*, &c. (which, as is ſaid before, are planted or raiſed in the Vacancies) are gathered, they dig, and ſow, at proper Diſtances, the Ground with *Beans*, *Kidney-Beans*, *Turnips*, *Beets*, or the like, and let the *Vines* ſhoot and grow at Liberty till the third Year, (that is, when they have been planted three Years compleat); then opening the Earth about each Plant in *March*, or towards the Beginning of *April*, to the Depth of about a Foot, they, with their Hands, clear away the ſuperficial Roots, and then throw in two Handfuls of good half-conſum'd Sheeps Dung, or elſe of Lupines that have been parboil'd; after which, with a ſharp Inſtrument (either a Bill or ſtrong Pruning-knife) and a ſteady Hand, they cut off the Head of the Plant juſt below the loweſt Shoot, which is ſometimes a Finger or two under Ground, rubbing the Part cut over with ſome of the contiguous Earth; and then upon its ſhooting, take the principal Shoot, (gently cleaning away the reſt) and fix it with a green Bulruſh to a ſmall Stick, to keep it, when tender, from being broken by the Winds, and ſo let it remain till the next Dreſſing Seaſon: when having prun'd it, leaving but one Eye, they put a Stick that is ſomething more ſubſtantial, of between three and four Feet long, to ſupport it from time to time, tying the Shoot to it till the Month of *July*, before the Entrance of the Dog-days; at which time they nip off the Head of it, which checks its Luxuriancy, and renders the Fruit, which it will then begin to have in ſmall Bunches of nine or ten *Grapes* each, better and larger, tying the Remainder of the ſaid Shoot to the Stick: In the next Year they order it in the ſame manner, and ſo on till the ſeventh Year after planting, when it begins to give Fruit to purpoſe; and then, at Dreſſing, they generally leave but one Head on the moſt vigorous Plants, and only two Eyes on that, and ſtake them with ſubſtantial Stakes of better than an Inch diameter, and near ſix Feet long, one of which, or more, goes into the Ground, (of which thoſe made of wild *Cheſnut*, the Coppices of which they cut once in ſeven or eight Years, for reſiſting both Wet and Dry, are accounted the beſt): and when they begin to ſhoot, they tie them to theſe with the ſmall Twigs of *Broom* or *Oyſters*, and ſo viſiting them frequently in the Courſe of the *Summer* to keep them ty'd, as alſo to nip off luxuriant Branches, they let them remain till the Dog-days are over; when they clear them of ſome of their Leaves, that the Fruit may ripen the better.

N. B. *In Dreſſing them after the ſixth Year, if they have made more Shoots than one, as moſt of them will have done, they, as before, cut them all away, unleſs they have Occaſion with them to ſupply the Places of ſome contiguous Plants that have miſcarryed; and in moiſt, warm Weather they lay thoſe Shoots down better than a Foot under the Ground, carrying the Heads of them where they deſign; and this they term* Propagation: *The beſt of the Shoots that they cut off from their* Vines *of ſeven Year* *old or older, they either reſerve for any new Plantations that they are to make, or to ſell, at about nine Pence* Sterling *per Hundred.*

In Dreſſing from the ſeventh Year forward, they reſerve the loweſt Head they can, provided it be vigorous, and endeavour to keep their Vines *as low as may be, for the Fruit to enjoy the warm Reflexion of the Earth after the Sun-beams are gone off from it, to ripen it, and give it Life and Vigour; but not ſo as to let the Ends of the Bunches touch the Ground, or be ſo near to it as that they might be daſh'd therewith by the Rains, ſince that would be apt to rot the* Grapes*; whilſt in* Chianti *(where the* Vines*, though moſt abundant in the Product of their Fruit, are not ſo laviſh in their Shoots, but are eaſily kept in good Order, by a Hand that is tolerably ſkilful) it is incredible how exactly even the* Vines *are kept, about the Height of four Feet from the Ground, which contributes to the making the beautiful Proſpect before-mentioned.*

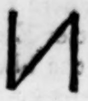
The Modern Way is as follows:

A Month or thereabouts after Planting, when the young Plants begin to ſhoot, they prune them juſt above the firſt Eye that remains out of the Earth, whereat, when they (as they naturally will) have made their Shoots, towards the Beginning of *June*, and ſo that they can diſcern which, of the ſeveral they put out, are the ſtrongeſt, and appear the moſt thriving, they carefully and gently, with the Thumb, rub off all of them, except one which they judge to be the ſtrongeſt, and, for the moſt part, the neareſt the Ground; which Diligence they renew every eight or ten Days, or oftner, if the Weather chance to be wet, taking away all the new Shoots, which they will abundantly make, ever leaving only the principal Shoot; which, that it may not be prejudiced by the Winds, or the Feet of the People, (who frequently, during the Progreſs of the Melons ſown between them, muſt go to nip off the running Branches, and cultivate them, and who at the ſame time with great Convenience, do this work about the Vines) they gently tie, as ſoon as it is well capable of it, to a ſmall Stick; and if, as it often happens, it proves very luxuriant, they nip off its Top: And this rubbing off of the young Shoots they continue 'till the Month of *October*, (though unleſs there be frequent Rains, there will, about the Beginning of *Auguſt*, be few Shoots to eaſe them of) whilſt ſometimes the principal Shoots will bear Fruits in ſmall Bunches of five or ſix Grapes each; but as they are always late, ſo they will not ripen: Wherefore, that the Strength of the Plant may not be leſſened or impaired thereby, they generally crop them off, after which they let the *Vines* remain 'till pretty early in the *Spring*, when the intermediate Crop of *Cauliflowers* or *Brocoli* of *Cauliflowers*, is taken off; then, in the Month of *February*, they open the Earth about the Foot of each Plant, and clear it of its ſuperficial Roots, and manure it in the Manner before deſcribed in the Cultivation of thoſe the *old Way*: The third Year they dreſs the Shoot ſo as to leave but one Eye upon it; and afterwards digging all the Ground in the intermediate Spaces, to requite the Expence of Culture, they ſow a Sort of Kidney-Beans, which not riſing above a Foot in Height, or ſcarce ſo much, does not prejudice the young *Vines*; to which they now give ſomewhat more ſubſtantial Sticks, whereto they continue to tie them, as alſo to rub off any new Shoots that they make, viſiting them for that End; as alſo to crop off the laviſh Tops of the Shoots, only three or four times in the *Summer*, and the next Year, in Dreſſing, they beſtow ſubſtantial Sticks on them, whereto they tie them with Broom-twigs, or ſmall Oſiers, when they begin to be in a pretty good State of Bearing, producing two or three pretty large Bunches of Grapes, which (as thoſe of the antecedent Year) ripen well, but come not to the full of their Bearing 'till the fourth or fifth Year: However, they anticipate thoſe ordered the other Way three or four Years; and this is withal the ſurer Way of the two; ſince in cutting off the Heads of the others, many are loſt; whereas this Way, few, if any, fail.

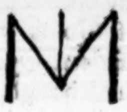
N. B. *What is before ſaid of a* Vine*'s coming to its full Bearing, is only to be underſtood in reſpect to the Quantity of the Fruit, a little more or leſs; for as to the Quality, it is generally eſteemed to be meliorating 'till the twentieth Year, (being duly cultivated) and the Wines coming from it richer and better; and in* Chianti *they mix not with their Grapes thoſe of the Product of* Vines *of a leſs Age than fifteen or ſixteen Years, and pretend they are always meliorating for fifty Years.*

The *Vines* being, by one or other of thoſe Methods, brought to a full Bearing-State, they muſt be annually dreſs'd, according to the Vigour of the Plant, and duly ſtak'd.

In Dreſſing, to thoſe of moderate Strength and Vigour, they leave but one eye, or at moſt two; and to the moſt ſtrong and vigorous, but three or four at the very moſt; and then they tie them not as they do when they are but one or two, but fixing another leſs ſubſtantial Stick in the Ground near the main one, to the Top of which, for its better Support, they tie it with an Oſier; they bend down and fix the Head thereto in the following Form:



And ſometimes when they find ſome one of a very extraordinary Vigour, and that has two good Heads, they leave them both, and diſpoſing of one in the manner juſt before related, the other, having fixed another Stick on the other Side of the principal Stake, and tied it thitherto, they in the like manner bend down the Tie thereto, when it comes to form the following Figure:



This done, they continue from time to time to bind the new Shoots to the Stakes, and to nip off the Tops of them, when too luxuriant, 'till towards the time of Ripening; when the Dog-Days are paſt, they diſburthen them of ſome of their Leaves, to expoſe the Fruit, then turning Colour, more to the Sun, and to accelerate the Ripening of it.

N. B. *What is ſaid above in relation to the leaving more than one Head, and the ordering thereof, only relates to ſuch as are in Vineyards on the Plains and Hills; for in the Mountains, as their Stakes are ſtronger and thicker, they affix ſome Wood-work to them, on which Frame they run two, and ſometimes three Heads, making the Shape of a Wheel.*

Here alſo it may be proper to obſerve, That all Landlords of Vineyards, at letting them, ever reſerve to themſelves the Privilege of viſiting them at their Pleaſure, to ſee if they are duly dreſſed, and not more Eyes left to a Vine *than there ought to be: For it is poſſible, in three Years Time, only by Pruning, to ſpoil the beſt Vineyard that is, paſt almoſt the Power of Art to recover it, and at the ſame time make it yield much Wine: For it is but leaving, inſtead of one or two Eyes, five or ſix, and of three or four, eight or nine, and it will be reduced unto ſo weak and exhauſted a State, and the* Vines *ſo run into Wood, that it will be paſt Recovery; and the only Method is to cut the* Vines *down a Foot or ſix Inches under Ground, and rear up a new Shoot, which, beſides the Time that will be loſt in ſo doing, will hardly, after all, prove effectual. And this Manner of pernicious Pruning the* Italians *call a* Laſcia Podera*, which, in* Engliſh*, is* Quit-Farm*; which is a proper Term enough.*

As for the Time of Dreſſing *Vines*, if it may properly be ſo called, there is nothing wherein thoſe People differ more; ſome performing it immediately after the Grapes are gathered, as in *Carignano* and *Val d' Arno*; others do it at all times as their Conveniency permits, and the Seaſon is mild and open, (leaving their youngeſt *Vines* 'till the laſt) from *November* to *March*; and in *Chianti*, as the Region is colder, and their *Vines* late to move, they do it late in the Month of *March*, and even to the Beginning of *April*. Others again do it at twice, in *November*, when they leave an Eye extraordinary, and in *March* they cut off that extraordinary Eye; which laſt Method ſeems to be the beſt; though to have Cuttings for any new Plantation, it can only properly be done in *February* or *March*.

As to Sowing in their Vineyards they alſo differ as much. In *Chianti*, they leaving a Space of about three Feet from their *Vines*, from thence to the low Wall, many ſow Wheat, and though the Soil ſeems to be little elſe but Stones, and ſuch as only can be worked by a Mattock, yet it bears prodigious Crops, thirteen or twenty for one: Others again, in that Space, will only ſow the low Sort of *Kidney-Beans*, *Lentiles*, and ſuch low Plants: And others again will not ſow any, the leaſt thing at all, as in the general they do not in the Vineyards on the Hills; but in the Plains, after the Heads of their *Vines* are riſen ſo high, as to be higher than the Tops of Beans, they make no Difficulty, between every Row of *Vines*, to ſow a Row of them, as the moſt Scrupulous do not, to ſow late in *April*, a Row of low *Kidney-Beans*; whilſt ſome of late, laying two Rows of *Vines* into one, whereof, with ſtrong Stakes and Canes, they make a ſort of Eſpaliers, and in the Middle (that is between Row and Row) being near four Feet from each, plant a Row of *Artichokes*, which, they ſay, being well dung'd in their proper Seaſons, Part of the Nouriſhment going to the *Vines*, does them more Good than Harm.

As for the Seaſon of digging their Vineyards, they all agree, that the later it is done in the Year, the better it is; wherefore, in the Places where they ſow nothing, they let that Work alone 'till the latter End of *April* or Beginning of *May*, when, according to the Nature of the Ground, they do it with the Spade or Mattock. And again, the more eſpecially to kill the Weeds, and to forward the Ripening of their Grapes, they ſtir it with a ſtrong Hough or Mattock, and, where they can, with a Spade, in the Dog-Days; but in ſo doing, they take a moſt particular Care that they touch not any of the Roots of the *Vines*; for that, if it did not kill them, would at leaſt make them wither and ſpoil their Fruit.

As for manuring their Vineyards, in all Parts, when they are in a bearing Condition, they practiſe it but once in five or ſix Years, when they open the Earth about the Roots, and taking away the ſmall ones, which then may have made towards the Superficies, they throw in an handful or two of Sheeps Dung, or of that of Goats or Deer; or if any of theſe are not eaſily or in ſufficient Quantity to be had, then, of parboil'd Lupines, which although agreeable to the *Vine*, yet being of little Subſtance, muſt be the oftner repeated, every three Years at leaſt; when they cover it again: and this they perform in the Months of *October* and *November*, that the *Winter* Rains falling thereon, may make it deſcend to the utmoſt Fibres of the Roots, and afford them Nouriſhment.

7. The Seaſon for gathering the Grapes, and making the Vintage is very uncertain, depending upon the Weather that has been the preceding *Spring* and *Summer*, which makes it ſooner or later 15 or 20 Days in *Chianti*; when the Seaſon has been good, they begin to cut their Grapes about *Michaelmas*, and in the Plains a Week or ten Days ſooner. In this they every where govern themſelves according to the Ripeneſs of their Grapes, and the Proſpect of the Weather, aiming to have a perfect dry Seaſon to do it in.

8. The Grapes being of a due Ripeneſs, and the Weather warm and dry, as ſoon as the Sun or Wind has dry'd up the Dew that was on them, they cut them, and put them into Piggins, and carry them, if at a Diſtance, on Mules, or if near, between two Men, to the Wine Fat, and then either bruiſing them to Maſh, in the ſaid Piggins, with a Club, throw them directly therein, or elſe into a thing reſembling a very large Hopper, with a Grate lengthwiſe; then Boards being placed over the Fat, a Lad with his Feet treads them out, the Juice, Husks, Stones, and Stalks all paſſing through the Grate into the Fat, and ſo they continue to do till the Fat (which uſually contains from four to five Tuns, ſometimes eight, ten, nay, as far as fifteen, or twenty in ſome large Vineyards, in which there are ſometimes ſeveral of them) is full, when immediately, or ſometimes in a few Hours before they fill it, it will ſet a boiling, which raiſes the Husks, Stalks, and Stones to the Top, and theſe make a thick Cruſt: and thus it continues boiling for many Days, more or leſs, according to the Strength of it, till it be fit to be drawn off, which is to be diſtinguiſhed by the Palate wherein the greateſt Skill in making Wine conſiſts. The Low Wines of the Plains are ready in about ten Days, thoſe of the Hills in about fifteen, of the Mountains in *Chianti* eighteen or twenty, and ſometimes more, in the Haſtening or Retarding whereof the Weather has ſome Share; ſo that when they are near ready, they taſte them every eight Hours.

N. B. *The more the Wines boil, the drier they will be, the Colour deeper; and the leſs the ſweeter and paler: and what is ſaid above, is to be underſtood of Red Wines, which are the chief Produce of this Country. Whilſt to make their ſtrong White-wines or Muſcadines, they gather their Grapes carefully, and lay them three or four Days, or more, in the Sun, taking Care to carry them within Doors, or under Shelters in the Night-time, that ſo no Dew may fall on them.*

And when they are put into the Fat, they let them boil but little, five or ſix Days at moſt, and then put them into the Caſk, ſhifting them from one Caſk to another, twice or thrice, to make them become fine; and for the Verdea *or* White Florence, *as it is called, they draw it off from the Fat almoſt as ſoon as it begins to boil, and has raiſed the Cruſt; and then letting it boil in the Caſk into which they have drawn it, thirty-ſix Hours, or, at moſt, two Days; they ſhift it into another, and ſo in a few Hours into a third and fourth, to check and prevent its Fermentation, which gives it the Sweetneſs it has; but then it is never perfectly fine, though ſome People both in* Italy *and* England, *eſpecially among the Women, are very fond of it.*

N. B. *Thoſe Grapes at the End of the Bunches are weaker in Quality, as well as leſs ripe, than thoſe that grow nigher to the Stalk; and therefore ſome extreme curious Perſons, to make a ſmall Quantity of very choice Wines, do cut them off, and make a Wine by itſelf, which is much inferior to that which is made of the upper Part of the Bunch. This Practice, though attended with Trouble, may be recommended for a larger Parcel, in ſuch Years as the Grapes are badly ripe, to have ſome Wine, at leaſt, in Perfection.*

N. B. *Thoſe Perſons who value themſelves on making the beſt Wines, and endeavour to keep up the Reputation of their Vineyards and Cellars, in cutting their Grapes, leave the unripe, or thoſe that are infected with Rottenneſs together, till the laſt, and with them make a Fat or more, by themſelves, of* Vin Scauro, *or* Refuſe Wine, *which ſerves for common Uſe; for which alſo they mix Water with the Bottom of their Fats, and the Husks,* &c. *and do make a pleaſant, briſk Drink, much preferable to Water-Cyder; but the Weather once coming in warm, turns it eager and undrinkable.*

When any Wines are boiling in the Fat, it raiſes a Warmth in the Room, which is accounted good in many Diſtempers, eſpecially for ſuch as have a Weakneſs in any of their Limbs, to put them into a Fat of boiling Wine; and the Husks, &c. *that come out of the Fat, are eſteemed very good for the like Purpoſe.*

9. When the Wines are found to be ready, they proceed to draw them off, which are now properly called *Wines*, (before which they are termed *Moſto*, i. e. in *Engliſh*, *Wort*) for which Purpoſe, within three or four Inches of the Bottom of the Fat, there is a Cock fix'd therein; when in ſmall Barrels they carry and put it into the large Buts, which in *Chianti*, hold, ſome of them, ſeven or eight Tuns, but generally two or three Tuns, made of thick Cheſnut, the Staves being better than an Inch and a half thick, and more than twice as high as they are long, which they never waſh; but having left a Gallon or two, or, it may be, three or four, of Wine in them, when they draw it off the *Spring* or *Summer* before: When they are about filling them again, to clear them out, they ſend in a Lad at the Door, which is made in the Head of the Caſk, to do it with a Spunge, and to waſh it with ſome new Wine; and this without wiping off any of the *Argol*, which they think preſerves the Wine the better.

In which Caſks, which laſt many Years, (and have *Argol* in them of the Thickneſs ſometimes of three or four Inches) they let them remain till they have an Opportunity of ſelling them, taking Care to keep them full quite to the Bung, with a wooden Stopper. This is what they practiſe in *Chianti*, where the beſt Wines are made, and whence, from thoſe Buts, they are drawn into Flaſks, and carried, at the Expence of about a Crown for a Mule Load, to *Florence*, in order for Exportation; but in other Places they draw them off into leſs Caſks, of which Wines, except ſome *Carniguano's*, and thoſe of *Val d' Arno*, few or none are exported, but ſerve for the Conſumption of the Country: Some of theſe have a pleaſant Flavour and Briſkneſs, tho' of no great Body, many of which will not keep the *Summer* over, except in cool Cellars, in the Places where made; ſuch is the nice Nature of this Country Wines in general. Nor are the choiceſt *Chianti's* exempt: For at two Seaſons of the Year, the Beginnings of *June* and *September*, the one when the Grapes are in Flower, and the other when they begin to ripen, ſome even of the beſt Wines are apt to change, eſpecially at this latter Seaſon: not that they turn eager, but take a moſt unpleaſing Taſte, which renders them unfit, not only for Drinking, but even to make Vinegar of; and is called the *Settembrine*. And what is moſt ſtrange, is, that one Caſk drawn out of the ſame Vat ſhall be infected, and another not; but be perfectly good, and yet both have been kept in the ſame Cellar too.

As this Change happens not to Wine in Flaſks, though that will turn eager, I am apt to attribute it to ſome Fault in filling the Caſk, which muſt always be kept full, which either by letting alone too long, till the Decreaſe be too great, and the Pan or Scum that there naturally is on all Wine, thereby being too much dilated, is ſubject to break, or elſe being broke by haſty filling up, gives it that vile Taſte of a rotten *Vine* Leaf.

But againſt this there is a very ſtrong Objection, that this Defect ſeizes the Wine at a particular Seaſon, in *September*, over which if it gets, it will hold good for many Years.

So the Caſe is worthy the Enquiry of the Naturaliſts, whilſt it is evident, at leaſt for the firſt Year after it is made, Wines in general are, more or leſs, affected by the Circumſtances wherein the *Vines* or Grapes at that time are; and if they get well over the time of the Grapes flowering, will keep good till that of their beginning to ripen.

As for the Time that the Wines are fit to drink, the poorer Sort of People drink that of the Plains almoſt as ſoon as drawn off; but from the 11th of *November* may be ſaid to be its proper Seaſon.

Thoſe of the Hills are a very pleaſant Drink about *Chriſtmas*, and during the *Spring*; but till *June* the *Chianti's* are not eſteemed to be fit for drinking, tho' they are fit for Exportation in Butts in *December*; and in the Flaſks and Cheſts about the Beginning of *February*: If ſooner ſhipped off in that Manner, tho' apparently fine, there will be a Sediment in the Flaſks.

The Art of Brewing Wines (further than the throwing into each great Butt, the Quantity of two or three Hatfuls of the choiceſt Grapes they had preſerved, and laid on Mats in the Sun for that Purpoſe, which were picked from the Stalks, and are eſteemed proper for their Wines to feed on, and which they call *Governo*) was not known in *Chianti*, (tho' the Hoſts here practiſed ſomething like it, mixing the ſmall Wines of this Country with the ſtrong ones of other Parts; and fining their White-wines with Iſinglaſs, Whites of Eggs, Lime, and the like; and were thought to put Allom into their Red Wines to preſerve them, and promote a Thirſt in their Gueſts) till on the breaking out of the firſt *French* War, an *Engliſh* Merchant from *Bourdeaux* came into theſe Parts, with a View to accommodate the Wines which were made in the beſt Parts of *Chianti*, and were naturally of a true bright Ruby, with a pleaſant Flavour, and a ſilky Softneſs, to the *Engliſh* Palates, then in love with the deep-colour'd rough Clarets; who inſtructed them firſt in the making of black Wines, with the *L'Abruſco* or *Wild Grape*; which being mixed with the *Chianti's* gave them a deeper Colour, and a rougher Taſte; and being liked in *England*, gave the firſt Occaſion to great Quantities being ſent thither every Year in Caſks: In the making of which, the ſaid Gentleman was the firſt that inſtructed them; for before, their Caſks were, as above related, very unweildy. This put them alſo (their being a Demand for their Wines) upon increaſing and enlarging their Cultivations, and making ſome of them in ſuch Places, as the Expoſition was not very proper for; as alſo to cultivate in Vineyards the ſaid *L'Abruſco*, or *Wild Grape*, and which certainly was the moſt proper to mix with their other Grapes in the Vat, boiling them together. So all ſucceeded pretty well, till the Year 1607, when the Vintage proving very bad, and there being a great Demand of their Wines for *England*, by mixing the low Wines with the high ones of *Chianti*, which that Seaſon were not very good, they brought theſe Wines into ſuch a Diſreputation, that they have never been able to regain their Credit, tho' they have ſince, many times, had thoſe that are good.

Whether it be that the Taſte of the People is run upon *Portugal* Wines, or ſome other Cauſe, they have never been able, as I ſaid, to recover it ſo as to have any conſiderable Quantity exported in Caſks from theſe Parts; and the Perſon that firſt directed the Affair, had the Diſſatisfaction to ſee his Project miſcarry, after it had in a manner ſucceeded, and himſelf reaped conſiderable Benefit thereby.

At preſent, therefore, what goes for *England* is chiefly in Cheſts, and no more black Wines, as uſed to be formerly, and theſe are ſent juſt as they are made; but ſtill in *Chianti*, as they have Cultivations of the *Bruſco* Grape (which, however, is much different from the *wild* one, and becomes much larger and more generous) they continue to mix them with their other Grapes, which gives the great Colour as well as a Roughneſs to their Wines, and is agreeable enough to the *Engliſh* Taſte.

Having thus acquainted you with what I know and can learn, in relation to the making and managing of Vineyards, and the Wines they produce, it remains for me to add an Evil, that, beſides the ordinary ones of Hails, Storms, and Froſts, attends the Cultivation of *Vines* in *Chianti*, and the Parts contiguous; for in the Plains there is no ſuch Thing; and that is, a very ſmall Kind of a blackiſh, or very dark-green Caterpillar, which in the Month of *May* attacks the young Shoots of the *Vines*, when the Grapes are in Embryo, and deſtroys them; for which, however, they have a moſt certain Remedy, which is, to make a little Ring of Birdlime round the Foot of each *Vine*, about eight Inches above the Ground, which none of theſe noxious Inſects (which, I preſume, proceed from the Earth, and are not brought in the Air, as ſome of the like are thought to be, though theſe come generally with an Eaſterly dry Wind) being able to paſs, moſt effectually does the Buſineſs; and as they in that Region come almoſt every Year, the Trouble of ſo providing againſt them is become habitual to the Cultivators.

The Manner of making Wine in Champaign, *and how it may be propagated in other Provinces, to bring it to Perfection.*

Wine is ſo delicate a Liquor, and an Aliment ſo proper to give Strength, and to preſerve Health, if uſed with Moderation, that one may very well wonder, that in moſt of the Provinces of *France*, they make it with ſo much Negligence, in all thoſe Places where it might be excellent.

The *Champenois* are exempted from this Reproach, and, whether it be from a Delicacy of Taſte, or a deſire of making an Advantage of their Wines, or a Facility in rendering them better, they have been always more induſtrious to make them more exquiſite, than thoſe of the other Provinces of the Kingdom.

It is true, it is ſcarce ſixty Years ſince they have ſtudied to make pale Wine, which is very near white; but before, their red Wine was made with more Care and Neatneſs than any other of the Wines of the Kingdom.

I ſhall not enter upon the ancient or modern Diſpute, as to the Preference between the Wines of *Champaign* and *Burgundy*; I ſhall content myſelf with taking Notice of all that the People of *Champaign* have invented, to give the Fineneſs and Agreeableneſs to their Wines; and by the Obſervations that may be made therefrom, it will be eaſy to ſee that the ſame may be imitated in other Provinces, ſo as to come pretty near that Lightneſs and Exquiſiteneſs.

If theſe Eſſays ſhall give Hopes of Succeſs for the future, the Wines of thoſe Provinces might be brought to Perfection by Degrees where they might be delicious, and where they are but too common, becauſe they have never ſtudied to give them that Fineneſs.

In order to have the Wine excellent, the *Vines* ought to be well expoſed to the Sun, eſpecially to the South; and alſo on the Decline, or in the manner of a little Hill, rather than on a Plain. *Vines* ſhould be well choſen, and ſhould be ſuch as generally produce none but ſmall black Grapes: The Bottom of the Soil ſhould be good; a little ſtony, and not naturally moiſt. The Grain of the Soil of *Champaign* is very fine, and has a ſingular Quality that is not found in the other Provinces.

As theſe Kinds of Lands are light, there is Occaſion to dung them from time to time, and to lay on new Earth. But the Dunging ought to be very ſparingly done; too much of it will render the Wine ſoft and inſipid, and apt to be ropy. It ought to be commonly Cow-dung, becauſe that is not ſo hot as Horſe-dung: In ſtrong Lands it may be mingled with Horſe-dung and Sheeps-dung, provided that the Horſe-dung be ſo rotten that it may be reduced to a Powder, and that there be but one half as much of the Cow-dung, otherwiſe it would burn the *Vines*. Let it be laid in a Trench or Pit, and mix one Layer of Dung and another of new Earth, and let it lie and rot during a whole *Winter*; and towards the Month of *February*, take from thence half a Baſket for every *Vine*, eſpecially for each new Plant, to help them to puſh forth. It is ſufficient for a Vineyard to be dunged once in eight or ten Years, or an eighth or a tenth Part every Year.

After the Dung has been carried, the *Vines* ought to be opened round about, and a little Trench to be made round the Foot of the *Vine*, and to be buried there at a proper Time.

Divers Perſons leave it there many Weeks before they bury it, but this is not the beſt Way; for the Air, the Cold or the Sun, will be apt to diſſipate the moſt ſubtil Subſtance of it; but when it is neither too cold nor too hot, it may be left open eight or ten Days, to exhale its ill Savour, eſpecially the Dung of Sheep.

They give to a *Vine* four ordinary Dreſſings, according to their Seaſons; but it is proper to take Notice of one Thing, which is ſcarcely obſerved in *Champaign*, which is, that they cut their *Vines* in the Month of *February*, and even in *January*; inſtead of which, they ought never to begin to cut them till after the 14th of *February*: When they are cut before, they puſh forth ſooner, and are expoſed to Injury, and are ſometimes killed, if any Hoar-froſts come preſently after they have been cut. But when they ſtay till after the 14th of the Month of *February*, there is no Danger of their being injured by the Froſts.

The Covetouſneſs of *Vignerons* leads them to undertake the Cultivation of more *Vines* than they can well manage; and for this Reaſon they cut their *Vines* in *January*, which does an infinite Injury to them, and to the greateſt Part of Plants, which they are ſenſible of for many Years.

In *Champaign* they cultivate two Sorts of *Vines*, which they call the *High Vines* and the *Low Vines*. The *High Vines* are ſuch as they leave to grow in thoſe Places that are leſs fine, to the Height of four or five Feet: The *Low Vines* are thoſe which they do not ſuffer to grow above three Feet high; theſe they interr, or *ravale*, according to the Country Term, every Year, ſo as to leave but a little of the End to appear, which is repeated annually.

The *High Vines* produce plentifully, and give often ſeven or eight Pieces of Wine an *Arpent:* The *Low Vines* produce but little; but then the Wine is much more delicate: They often do not give above two Pieces of Wine an *Arpent*, oftentimes leſs, ſeldom three, but much ſeldomer four.

In order that the Wine may be the finer, all the *Vines* which give the white Grapes muſt be taken away, and thoſe alſo that give the large black Grapes; but one need not pluck theſe up, but graft them.

But ſometimes theſe Grafts will not ſucceed; which being obſerved, they muſt be plucked up, and new ones that have a Root, ſet in their Room, which they chuſe out of the Nurſeries, that are common in the Country. They ordinarily purchaſe theſe Plants for a Piſtole a thouſand.

A private Man, that has a great many *Vines*, may make himſelf Nurſeries.

Theſe Plants that have a Root are put into the Earth, in the Middle of a great Hole, about a Foot deep, which they make with a Stake, or ſtrait Mattock, or Pick-axe; and theſe produce ſooner than the others which have no Root: A Plant that has a Root begins to give Wine, a little, the third Year, indifferently the fourth and fifth, and in abundance in the following Years, and ſo for above ſixty Years.

Theſe new Plants ought to be dunged the ſecond Year, and in the ſixth Year, and afterwards in the eighth and tenth Year, as other *Vines*.

It will be to the Purpoſe, every Year, to pull up Part of the old Plants, which take up Room, and produce little or nothing; and by this Means a Vineyard will be conſtantly renewed, as one may ſay, and in a perfect good Condition.

When there are Dews or Humidities, in *May*, *June* and *September*, the *Vignerons* muſt not be ſuffered to enter the Vineyards in a Morning; for the Dews of theſe Months are commonly very cold, if the Sun do not draw them up; which burns the Leaves of the *Vines* which it touches before they are drawn up.

It is very eſſential not to enter the Vineyards at the Time when there is Hoar-froſt, or Showers attended with Froſt, for this will certainly kill the *Vines*.

The Vineyards muſt be weeded now and then, and if there be any Beetles, which are pernicious Animals to Plants, they muſt be picked off, and put into Sacks, and burnt at ſome Diſtance from the Vineyard, and the Aſhes buried.

About the End of *June*, and alſo of the Month of *May*, according as the Vineyard is advanced, it is neceſſary to cut off the End of each Twig, that the Plant may grow no more in Height, and that it may convey all its Nouriſhment to the Grapes: It is enough, if it have two Feet and an half, or three at moſt, above the Ground; all the reſt is to be cut off, as muſt alſo the Tops or Ends of the young Shoots, which proceed from the Bottom or Sides of the Stocks. This ought to be done twice or thrice, or four times in a *Summer*, according as the *Vines* put forth, more or leſs, in certain Years.

In the Seaſon, they put a Prop to every *Vine*, to ſupport it; they ought to be choſen, as much as may be, of Oak, and to procure them of the Quarter or Heart thereof, if you are willing to go to the Charge of it. Theſe will laſt above twenty Years, and when they are once made ſharp, they will always keep ſo; for when they begin to rot, they periſh equally throughout, and remain always pointed: The others laſt ſcarce four or five Years; and the Maſters muſt have an Eye over the Servants when they ſharpen them yearly, that they do not cut them too much, and make them too ſhort, and that they do not break a great many that might ſerve; for oftentimes in cutting off that which is rotted, they cut off two or three Inches of that which is ſound, or that which is good, which prejudices it as to Duration. They call theſe Props, *Foot Props*.

When a Vineyard has been cultivated and managed for the Year, after the accuſtomed Manner, and the Vintage-time approaches; when they have made Choice of and prepared a new Caſk that will contain it; and when the Preſs has been waſh'd, cleans'd, and greas'd, you muſt be very watchful to find when the Grapes are come to Maturity. For if the Grapes are too ripe, the Wine will not be ſufficiently ſtrong; if they are too green, it will be hard, more difficult, and longer before it is fit to be drank.

In the Provinces of *Languedoc* and *Provence*, the Grapes have too large Stones; they have too many white ones, they ſuffer them to be too ripe, which gives them over-much Liquor; they let their Stocks grow to be too old, and do not renew them often enough. They are planted, for the moſt part, upon too good Bottoms, or too moiſt, and have not an Aſpect of the Sun good enough.

To make an excellent Wine of the firſt Preſſing, having firſt well examined the Maturity of the Grapes, you ought to endeavour not to gather them but on Days that are very dewy, and in hot Years, after a little Rain, when you can be ſo happy as to have it; as the Grapes are not ripe till towards the End of *September*, and ſometimes the Beginning of *October*, Dew is rarely wanting in Vintage-time. This Dew gives the Grapes a Flower or *Farina* on the Outſide, which they call *Azur*, and inwardly a Freſhneſs, which cauſes that it does not heat very eaſily, and that the Wine is not colour'd.

It is very lucky, if there chances to be a miſty Day in dry Years, which now and then happens: The Wine is not only thence more white and delicate, but the Quantity is by much the greater, being augmented by near one fourth Part: A private Perſon who has but twelve Pieces of Wine, in gathering his Vintage in a Morning which has the Sun without Dew, will have ſixteen or ſeventeen if the Morning be miſty, and fourteen or fifteen if it has no Miſt, but yet has a good Dew: The Reaſon of this is, that the Dew, and, above all, the Miſt, renders the Grapes tender, ſo that the Whole, in a manner, turns into Wine.

The Wine produc'd from the Grapes that have not been warm'd the Moment they are cut, will ſtill remain much paler; whereas when the Sun has warm'd the Subſtance of the Grape, it will become more red by the Motion of the Parts; but the Quantity will be leſſen'd either by reaſon of Tranſpiration, or becauſe the Rind has been thicken'd and harden'd by the Sun, whereby it yields its Juice with more Difficulty. This, Experience hath taught, is of ſo much the more Concern, by how much the more certain it is.

They agree in *Champaign*, that the Wine which they call *River Wine* is ordinarily paler than that of the *Mountains*, but they do not give the Reaſon for it. I believe the Vineyards that are near a *River* enjoy all the Night a freſh Air, which the *River* exhales; whereas the Vineyards of *Mountains* don't reſpire, during the Night, that Warmth, which proceeds from the Exhalations of the Earth, and it is that which makes the Colour more or leſs; alſo when the Years are very hot, they cannot, either to thoſe of the *River* or of the *Mountains*, warrant the Colour; and when the Years are cold, neither the Wines of the *Mountains*, nor thoſe of the *Rivers* are colour'd: the Reaſon is the ſame, becauſe the Wines of the *Rivers* are more ſoft, forward, and ſooner fit for drinking, than the others that are harder, more heady and later fit: They call the Wines of the River, *Auvillé*, *Ay*, *Epernay*, *Cumieres*, *Pierry*, as *Fluery*, *Damery*, *Vanteüil*, and others; but *Verzenay*, *Sillery*, *St. Thierry*, *Mailly*, *Rilly*, and ſome others are of the *Mountains*; theſe latter Wines keep as well as the firſt, and, in good Years, they keep equally well in Bottles for five or ſix Years.

They gather not all the Grapes without Diſtinction, neither, at all Hours in the Day, but they chuſe the ripeſt and blueſt; thoſe are the beſt, and make the moſt exquiſite Wine, whoſe Berries grow not too cloſe together, but are a little ſeparated, whereby they ripen perfectly well: For thoſe that are cloſe join'd together, never ripen throughly: They cut them with a ſmall crooked Knife, with as much Neatneſs, and as little of the Tail as they can, and they lay them very gently on the Baſkets, ſo as not to bruiſe one Grape.

With thirty Grape-gatherers they will run over a Vineyard of thirty Arpens in three or four Hours, to make one firſt Preſſing of ten or twelve Pieces.

In wet Years, great Care ſhould be taken not to put any Grape that is ſpoil'd into the Baſkets; and at all times you muſt be very careful to cut away the rotten Grapes, or thoſe that are bruis'd, or quite dry'd up; but you muſt never ſtone them.

They begin the gathering of Grapes half an Hour after Sun-riſing; if the Sun is not clouded, and it is a little hot, about nine or ten o'Clock they leave off gathering, and make their *Sac*, which is one of the firſt Preſſing; becauſe after this Hour the Grape being warm, the Wine will be of a red Colour or Teint, and will be a long while very heady.

Upon theſe Occaſions they get a great Number of Gatherers, to be able to make up a *Sac* for a Preſſing in two or three Hours: If it be overcaſt, they may gather the whole

Day, becauſe the Grape will preſerve its Freſhneſs upon the Stock.

The Gatherers and the Preſſers ought to take great Care that the Grapes be neither foul nor heated when they are preſs'd; and alſo, that the Grapes have their Flower under the Preſs.

When the Preſs is near the Vineyard, it is eaſie to prevent the Wine from having a Colour, becauſe the Grapes may be carry'd gently and neatly in a little time; but when they are two or three Leagues off, they being oblig'd to ſend the Grapes in Caſks, and in Carts, to preſs it as ſoon as may be, it is hardly to be avoided but that the Wine will be colour'd, except in very moiſt and cold Years.

This is a certain Principle, that when the Grapes are cut, the ſooner they are preſs'd, the more pale and delicate is the Wine; for by how much the more the Wine ſtands upon the *Marc*, the redder it is; ſo that it is of great Importance to haſten the Gathering of the Grapes, and Preſſing of them.

The Preſſes of *Champaign* are very commodious; the particular Perſons that have many Vineyards of their own, have them in or near the ſame Vineyards: In ſmall Places the Preſſes are *Bannaux*, which are of different Sizes and Faſhions. An exact Deſcription of theſe ſeveral Preſſes will be inſerted in the Article of *Wines*.

The ſmall ones are about ſeven Feet and a quarter, the middle ones about ten or twelve, the large ones fifteen or eighteen; the leaſt, which they call *Etiquets*, coſts ſeven or eight hundred Livres; the ſecond, which they call a *Cage*, or a *Teiſſons*, about two thouſand Franks; the large ones a thouſand Crowns, and ſometimes more, according as the Wood is cheaper or dearer in certain Places: In *Languedoc* and *Provence*, where Wood is ſcarce, theſe Sort of Preſſes coſt a very great Price, and but few Perſons are in Circumſtances to be at the Charge of them.

When the Grapes have been put under the Preſs or on the *Marc*, they put three great Rods or Poles of ten or twelve Inches round upon them one at either End in Length, and the third in the Middle on the ſame Side: Theſe at the Extremities ſerve to deſcribe the Lines which they ought to follow with their Cutting-ſhovels, in cutting the *Marc*, the Subſtance ſqueez'd on two Sides: After the Cut is made, they lay upon theſe Poles, and on the Grapes, Planks of the Size of the Preſs; and upon theſe Planks half Beams of eight or nine Inches ſquare, which they call *Moyaux*, at a Foot diſtance one from the other; they put four or five Rows of theſe *Moyaux* acroſs one upon another, which elevates it with the Bag about four or five Feet; and they let down upon the Whole three or four great Beams of an immenſe Weight, which are plac'd in the Middle of the Preſs acroſs, and borne up at one End by two ſtrong Side-beams, which are ſunk fifteen or twenty Feet into the Ground, and which are faſten'd to the Baſes which croſs them; at the other End there is a *Cage*, as they call it, or a Wheel with a Skrew to raiſe or lower theſe great Beams upon the *Moyaux*, and thus to preſs the Grapes: Then they preſently raiſe, by the Means of a Skrew, the End of the Trees on the Side of the Wheel or of the *Cage*, which lowers the other End of the Cheeks or Side-Beams; then they drive with a great Mallet two or four great wooden Quoins between the Notch which is in the Side-beams or Cheeks, and theſe Beams are alſo lower'd to keep them in their Poſition, and to prevent them from riſing; and after this they lower the other End by the Aid of the Skrew, which ſerves alſo raiſe it.

They uſe in theſe Preſſes, large Steel Shovels about a Foot in Breadth, and one and a half in Depth, very heavy and ſharp at the Bottom, to cut the *Marc* of the Grapes eaſily at the four Sides.

The firſt time they lower the great Beams upon the Grapes, they call the Wine that runs out, the *Wine* of *Goute*, becauſe it is the fineſt and moſt exquiſite in the Grape: This Wine is very thin, and has not Body enough; they call this firſt Preſſing *l'Abaiſſement:* This muſt be done with a great deal of Dexterity and Briſkneſs, that the Beams may be rais'd immediately, to ſend back to the Middle inſtantly the Grapes which are ſlipp'd to the Sides all round about, to preſs them briſkly the ſecond or third time. They call theſe two other Lowerings of the Beams, the firſt and ſecond Cutting: They muſt be done in leſs than an Hour, if you would have the Wine very pale, becauſe Time is not to be given to the Grapes to heat, nor the Liquor to remain upon the *Marc*.

They ordinarily mingle the Wine of the *Abaiſſement*, or Lowering with that of the firſt and ſecond Cut; and ſometimes, but very rarely, with that of the third, according as the Years are more or leſs hot, and thence they call a Wine of the firſt preſſing, Fine.

Some preſerve one or two *Carteaux* of the firſt Taſte, which is that of the Lowering, by itſelf; but it is too ſmall or thin, and has not a ſufficient Body for Wine.

There are ſome ſkilful Perſons who pretend, that the Lowerings of the Wines ought not to be mix'd but with thoſe of the firſt Cut, becauſe that is much more delicate than that of the ſecond and third; and that beſides, there is time enough to mingle them afterwards, if they are found to be too fine, and pale enough, and the rather, becauſe there is no Remedy if it be done at the firſt.

At every Cut they raiſe the great Beams, and they take away all the *Moyaux* with the Planks, and the Rods that are immediately upon the Grapes, or upon the *Marc*; with theſe Steel Cutting-Shovels they cut the *Marc* on four Sides, and they caſt down with their wooden Shovels that which is cut, and they ſpread it even all over the Square to the End, that it may not diſperſe ſo eaſily; that is to ſay, in thoſe Preſſes which they call *Etiquets*; they take Care that the Wheel which is upon the Middle may be made to bear, eſpecially upon the Rammer, over all the Breadth, in ſuch manner that the Bag may be equal.

Inſtead of the Preſſes, [a *Cage*] or *Teiſſons*, as the Beams bear more upon the Side of the Wheel than on the Sides of the Corners, there muſt needs be more of the *Marc* when the Bag is placed ſloping toward the Wheel than toward the Side of the Quoins, as will be eaſily comprehended by viewing the Deſcriptions of the different Preſſes. It is alſo to be obſerv'd, that every time they cut the Grapes or the *Marc*, they tie up the Bag, becauſe it has always a certain Elevation, in ſuch Sort that it is one-third leſs at the End than at the Beginning.

The ſecond Cut is more plentiful than the Lowering and the firſt, becauſe the Grapes begin to be well bruiſed, and they do not ſlip ſo much to the Sides.

The Wine ſtrains from the Preſs into a Punchion, having the Head ſtav'd out, or ſome other large Veſſel prepar'd for the Purpoſe, and ſunk into the Ground on the Foreſide to receive it; it appears to be drawn a little upon the Red, but it loſes this little of its Colour, according as it is boiling, and as it clarifies itſelf in the Tun; and it remains perfectly white, eſpecially when they have preſſed the two firſt Cuts with much Diſpatch; but principally when they have gather'd the Grapes during the Dew, or in a ſhady Time. Altho' theſe Wines are white, they call them grey, becauſe they are made only of black Grapes.

If the Year be hot, and the Wine of the third Cut has a Colour, it muſt be mingled, not with that of the foregoing, but with that of the fourth, and ſometimes, though but very rarely, with that of the fifth. They are not in ſo much Haſte for theſe Cuts as for the firſt; they make an Interval of a good half Hour between the one and the other: The Wine that comes thence has more of Colour than this, which they call the *Partridge's Eye*; or, the *Wine of the Cut:* It is a ſtrong Wine, pleaſant, fine, good for an Ordinary, but is better when it is old.

When the Wine of the fourth Cut is too deep, they don't mingle it with Wine of the Cut, but they obſerve to mingle it with Wine of the fifth, ſixth, or ſeventh Cut, which they call *Wine of the Preſs*, which is two red, pretty hard, but fit for Houſhold-drinking: But when they are not in haſte, they leave an Interval of an Hour and a half between every one of the three laſt Cuts; as much to give time to the Wine to ſtrain inſenſibly, as to give the Preſſers time to ſleep, or to reſt themſelves; for the Fatigue is very great, they being oblig'd to carry it on Night and Day for about three Weeks. The Preſſers of *Champaign* preſs the Grapes ſo hard, that after they have done, the *Marc* is as hard as a Stone: They put this *Marc* into old Caſks, with the Heads out, and they ſell it to People, who draw from it an *Aqua Vitæ* of a very bad Taſte, which they call the *Aqua Vitæ* of *Aixne*; but it is good for a great many Purpoſes.

Thoſe who have many Vineyards, alſo make two, three, or four firſt Preſſings of fine Wine, by chuſing always the moſt delicate and ripeſt Grapes for their Firſts: Theſe are always much ſuperior the one to the other for Goodneſs and for Price; ſo that if the Wine of one of the firſt Preſſings ſells for ſix hundred Livres a *Queüe*, that of the ſecond will not ſell for above four hundred and fifty, and that of the third two hundred and fifty, although all the Wines are of one and the ſame Vineyard.

In every firſt Preſſing there are ordinarily two-thirds of fine Wine, one half third of Wine of the Cut, and one half third of the Wine of the Preſs: Thus one *Cuvée* of five or ſix Pieces of Wine will conſiſt of nine or ten of Fine, three or four of *Taille*, and two or three of the Preſs.

Of the common Black Grapes, which remain after one ſecond or third *Cuvée*, they make one with thoſe that are not very ripe, and which they call *Verderons:* They make of the Whole a Wine pretty high colour'd, which they ſell to the Country People, or that ſerves for their Domeſticks: They alſo leave theſe Grapes two whole Days in a great Tub, before they preſs them, to the End that the Wine may be the redder; and they mingle all that comes from the different *Tailles* of this Vintage.

The white Grapes don't come into this *Cuvée*; they leave them upon the Stock till towards *All Saints-Day*, or ſometimes till towards the eighth or tenth of *November*, at which time the Mornings are cold, to make of it a *Vin-Bourra*, as they call it, (*i. e.* a new and ſweet White Wine, that has not work'd) which they ſell while it is quite hot.

This Wine is ſtill the better when the Grapes have borne the white Froſts of *October* and *November*, or at leaſt very cold Mornings: A little Rottenneſs in theſe Grapes does no Harm; you need only take Care to give the Wine leave to throw out the Filth by the Ferment, and purify.

This White Wine may be mingled with the Wine of the *Taille*, if you will, if you have not an Opportunity of ſelling it preſently after it is boil'd. This makes a very good Wine to drink, is pretty pale, and has a good Body.

All theſe fine Wines ought to be put into a new Caſk, as alſo ſhould thoſe of the *Taille*; but the Red Wines, the Green, and thoſe of the Preſs may be put into an old Caſk, but it ought to be a good one.

You muſt never do the Tuns over with Brimſtone; you ſhould only waſh them in common Water, a little time before they are fill'd, and give them time to drain well: Some Handfuls of Flowers or Peach-leaves may be mingled with the Water; and they pretend that this will do the Wine good.

In *Champaign* they rarely put it in any thing but Pieces [*Carteux*] and Cades.

The *River* Meaſure is different from that of the *Mountains:* The Pieces of the *Rivers* contain about two hundred and ten *Paris* Pints (a *Paris* Pint is equal to an *Engliſh* Quart) the *Carteau* an hundred and ten; the Pieces of the *Mountains* contain about two hundred and forty Pints, at the leaſt two hundred and thirty *Paris* Meaſure, and the *Carteau* an hundred and fifteen or an hundred and twenty.

They mark regularly, with Chalk, every Piece and every *Carteau*, which denotes the firſt, ſecond or third *Cuvée*; the Wine of the Cutting, of the Preſs, the White Wine and the Green; they alſo write the Name of the Vineyard from whence the Grapes came.

Some few Years ſince, ſome private Perſons in *Champaign* have attempted to make Wine as red as that of *Burgundy*, and they have ſucceeded pretty well as to the Colour; but, in my Opinion, theſe Sorts of Wines do not come up to thoſe of *Burgundy*, in that they are not ſo ſoft, nor ſo agreeable to the Palate: Nevertheleſs many Perſons call for theſe Wines; and ſome eſteem them the beſt.

And as thoſe Grey Wines are a little fallen, there was made, the laſt Year, a great deal of Red in *Champaign*. Theſe Wines do well for *Flanders*, where they are frequently ſold for thoſe of *Burgundy*.

Of all theſe Wines, there is none better for Health, nor more agreeable to the Palate than the Grey Wine of *Champaign*, of the Colour of a *Partridge's Eye*, or the Wines of the two firſt *Tallies* of a firſt Preſſing in pretty hot Years.

This Wine has a Body, a Tartneſs, a Headineſs, a Balſamickneſs or Perfume, a Quickneſs and Delicateneſs, that exceeds all the moſt exquiſite ones *Burgundy*.

And that which ſhould engage one to drink it, is its Lightneſs, which makes it ſtrain and paſs quicker through the Body than any other Wine in the Kingdom. It is a Miſtake to be of Opinion, that the Wine of *Champaign* can give the Gout. I have ſcarce ever ſeen one gouty Perſon in this whole Province; and there need be no better Proof.

To make good Wine in *Champaign*, the Black Grapes ought to be gather'd in the Heat of the Day; Care is to be taken to chuſe them well, and not to mingle with them the Grapes of the Vine-Arbour, nor the Green ones, or thoſe that are partly rotten; to let them be two Days in one Tub, where the Liquor grows red by the Heat that it contracts there: Some Hours before it is put into the Preſs, it ought to be trampled with the Feet, and the Juice to be mingled with the *Marc:* Without this, the Wine will not be of a ſufficient Redneſs. If it be let ſtand more than two Days in the Tub, it will taſte too much of the Stone. If it be mingled with the Wine of the Preſs, it will be too thick, too hard, and too unpleaſant.

If they would continue to make good Red Wine in *Champaign*, they muſt trample the Grapes as in *Burgundy*, and leave them for three, four or five Days in one Tub: But as the Red Wine of *Champaign* never equals the Goodneſs of that of *Burgundy*, the Reputation of the grey Wines will ſink in a ſhort Time, and the Publick will inſenſibly loſe the Reliſh of it, and this will bring an infinite Detriment to the Province.

The Wine of the firſt Preſſing being finiſh'd, and the Veſſels marked, they ſet them in a Row in a Cellar or Court-yard. Thoſe who have a great deal of Wine, and are good OEconomiſts, take great Care to gather the Scum that comes out of every Veſſel, while the Wines ferment, by the means of a kind of Tin Funnel, made bending downwards, which lets the Scum fall into a wooden Bowl, which is placed between two Caſks; they afterwards put theſe Scums into the Wines of the Preſs: but, nevertheleſs, there are but few that uſe this Piece of OEconomy.

They let theſe Grey Wines ſtand to ferment in the Caſks ten or twelve Days, becauſe theſe Wines throw out their Ferment ſo much the more or leſs ſlowly, by how much they have more or leſs Warmth, or as the Years are more or leſs hot.

After the Wine has done fermenting, they ſtop up the Veſſels at the great Bung-hole, and leave on the Side forward an Opening, about the Bigneſs of a *French* Farthiny, by which one may put in his Finger; this they call *le Broqueleur:* And they ſtop this up ten or twelve Days after, with a wooden Peg of about two Inches long, for the more readily taking out and putting it in.

All the while the Wines are fermenting, the Veſſels are to be kept almoſt full, to give them an Opportunity of caſting out all that is impure. In order for this they muſt be filled up for three Days, within two Fingers of the Bung; after they have been bung'd up, they muſt be filled up every eighth Day, at the little Hole, for the Space of two or three Weeks more; and after that, once a Day for fifteen Days during one Month or two; and after that once every two Months, as long as the Wine remains in the Vault, if it be there for Years.

When the Wines have not Body enough, or are too green, as it often happens in moiſt, cold Years, and when they have too much Liquor, as in hot and dry Years; three Weeks after the Wines have been made, they muſt be rolled in the Caſks five or ſix Turns, to mingle them well with the Lees, and this muſt be continued every eight Days, for three or four Weeks; this Mingling of the Lee with the Wine being repeated, will ſtrengthen it, ſoften it, ripen it, and render it more forward, and make it fit to drink in as ſhort time as if it had been tranſported from one Place to another.

Theſe Wines muſt be let ſtand in the Cellar till towards the tenth of *April*, when they carry them down into the Vault; but as ſoon as it begins to be cold, they are to be carryed up again into the Cellar: It is of Conſequence to be obſerved, upon this Subject, that the Wines ought always to be in cool Places, and never to ſuffer the Heat. And as the Vaults are cool in the *Summer*, and warm in the *Winter*, as ſoon as it begins to be hot, the Wines muſt be carryed down, whether they be in Pieces or in Bottles, into the Vaults; and when it begins to be cold, they muſt be carryed up into the Cellar.

There has been nothing better invented and more uſeful than the Manner of Drawing off Wines. Certain Experience convinces, that it is the Lee that ſpoils Wines; and that they are never better nor more lively than when they have been well drawn off, whether you would Bottle it or keep it in the Pieces: It ought always to be drawn off out of one Veſſel into another, at leaſt twice into another Veſſel well waſhed, leaving the Lee in the former.

You ſhould draw off the Wines the firſt time towards the Middle of *December*; the ſecond towards the Middle of *February*, and to fine them in *March* or *April*, eight Days or thereabouts before you bottle it. For every Piece of Wine you muſt have of Iſinglaſs, that is the whiteſt, of the Weight of a Crown of Gold, weighing two Deniers fifteen Grains, or ſixty three Grains. They take ſo many times the Weight of a Crown of Gold as they have Pieces of Wine to draw off, they put this Quantity of Iſinglaſs in one or two Pints of the ſame Wine in a Bucket for a Day or two, to give it time to diſſolve; others put it in a Glaſs, or a Pint of Water, according to the Quantity, in order to haſten its diſſolving, which is always difficult to be done; ſome mix it in a Chopin or Pint of Spirit of Wine, or excellent *Aqua Vitæ:* When the Iſinglaſs is grown ſoft, they handle it well to divide it, and diſtribute it; then, when the Parts begin to ſeparate, they put in the Bucket or the Veſſel in which this Diſſolution is made, ſo many Pints of Wine as they have Caſks or Pieces to draw off; then they handle the Iſinglaſs well again, and paſs it through a Strainer, the Holes of which ſhould be very ſmall: They often pour in of the ſame Wine to dilute it well; and when there remains nothing in the Strainer, they paſs all the Liquor over again through a Linen-Cloth, and ſqueeze it very well, and afterwards they put one good Pint or leſs into each Caſk, and half into each *Carteau*.

They ſtir the Wine in the Piece with a Stick about the Middle, without ſuffering the Stick to go any lower. It is ſufficient to ſtir the Wine for the Space of three or four Minutes.

A certain private Perſon has newly contrived a quicker Method of diſſolving this Iſinglaſs: After it has been ſteeped one Day in Water, he melts it in a Skillet upon the Fire, and reduces it to a Ball, like a Bit of Paſte, and afterwards puts it into the Wine, where it diſtributes itſelf with leſs Difficulty. After what manner ſoever it be diſſolved, Care ought to be taken, not to put in too much Liquor, and not to put more than a proportionable Quantity of Water or Wine to that of the Iſinglaſs.

The Iſinglaſs works its Effect ordinarily in two or three Days; tho' ſometimes it does not clarify the Wine in ſix or eight; but nevertheleſs you muſt wait till the Wine is clear before you change the Veſſel. In the Winter the Seaſons are oftentimes ſo improper for this, that there is a Neceſſity of putting Iſinglaſs a ſecond time into the Piece, but then you muſt not put in more than the Quantity before mentioned: But when it freezes, or the Weather is clear and cold, the Wine will clarify itſelf perfectly well, and in fewer Days: It has a Colour more lively and brilliant, than when it is fined and drawn off in faint, moiſt Weather.

As ſoon as the Wines are clear, they are to be drawn off, and the Veſſels changed. Four or five new Caſks are ſufficient to draw off two or three hundred Pieces of Wine; for when they have empty'd one Piece, they take out the Lee, and put it into the old Caſks, waſh it, and it ſerves to draw off another into it.

Nothing is more curious than their Contrivance in *Champaign*, to ſhift their Wines without diſplacing their Caſks. They have a Leathern Pipe, like a Gut, four or five Feet long and about ſix or ſeven Inches in Circumference, well ſew'd with a double Seam, that the Wine may not run through: There is at both Ends a Cannon or Pipe of Wood, about ten or twelve Inches long, and about ſix or ſeven in Circumference at one End, and about four at the other: The great End of each Pipe is ſet in a Leathern Pipe, and well bound with ſtrong Twine on the Outſide, that the Wine may not run out: They take out the Bung that is at the Bottom of the Tun that they would fill, and drive the Wood of the Pipe in with a wooden Mallet, which they beat upon a Sort of Chin-cloth, that is to each of theſe Pipes, which being rais'd about two Inches from an Inch or leſs of the great End, and which loſes itſelf inſenſibly in going towards the ſmall End; they ſet a large Syphon of Metal below the Caſk they would empty, and alſo put into this Syphon the ſmall End of the other Pipe of Wood, which is faſten'd to the Leather Pipe, and afterwards open the Syphon; and without the Help of any Perſon, almoſt the half of the full Veſſel paſſes into the empty one by the Weight of the Liquor; and when it is come near the Level, and will run no longer, they have Recourſe to a Kind of Bellows, of a very particular Conſtruction, to force the Wine from the Caſk they would empty, to paſs into that they would fill.

Theſe Kinds of Bellows are about three Feet long, and a Foot and half broad; and are made and ſhaped in the common Manner to about four Inches of the ſmall End; but from this Diſtance the Bellows have three or four Inches in Breadth. In the Inſide of this Place, the Air paſſes only through one great Hole of an Inch bore: Near this Hole, on the Side of the ſmall End of the Bellows, there is a Piece of Leather, like a Tongue or Sucker of a Pump, which is faſten'd there, and lies cloſe againſt the Side of the Hole and the Mouth, when the Bellows is lifted up to take in the Air, that the Air which has paſſed once through this Hole, and which has entered into the Caſk, cannot return back into the Bellows; which takes not back a new Air, but by thoſe Holes below to fill it again.

The End of the Bellows is different from that of others, being cloſely ſhut up with a Nozle of Wood of a Foot long, which is jointed in, glued, and very ſtrongly faſtened by good Pegs at the End of the Bellows, to conduct the Air downwards: This Nozle is round and thick without, about nine or ten Inches in Circumference at the Top, and diminiſhes inſenſibly towards the ſmall End, that it may enter conveniently into the Veſſels by the Bung-hole, and alſo to ſhut it up ſo cloſe that the Air can neither get in nor out any Way.

This Nozle enters for this Purpoſe two Inches, near the Level at the End of the Bellows, and is made in a half Round at the Top, that it may be beaten in with a Wooden Mallet, and forced into the Caſk: There is, about two Fingers Length below the upper End of this Nozle, a Hook or Brace of Iron of a Foot long, paſſing thro' an Iron Ring, which is faſtened with Nails to the Nozle, in order by this Hook to faſten the Bellows to the Hoops of the Caſk, without which the Force of the Air would drive the Bellows out again by the Bung-hole, and the Operation of emptying the broached Veſſel would not be performed.

The Mechaniſm of theſe Bellows thus deſcribed is eaſy to be conceiv'd: The Air enters by the Holes below in the common Manner: It advances towards the End, according to the Degree that the Bellows are preſſed: There it meets with a Pipe that cauſes it to deſcend downwards; but to hinder it from riſing up again, as it would do, when the Bellows were opened to give it a new Air, there is in this Space a Sucker or Tongue of Leather, which, as has been ſaid, is the Inſide of the Hole at about three or four Inches from the End of the Bellows which ſhut up the Hole according as you would have it take in again a new Air; this new Air puſhes ſtill gently, in preſſing the Bellows in the Pipe, becauſe this Tongue opens according as it is forced by the Air; thus there continually enters a new Air into the Caſk, without being able to get out, becauſe it finds itſelf cloſe ſtopped by the ſame Pipe that carries the Air into it, and the Tongue hinders it from getting up again.

The Force of this Air, which continually puſhes in, preſſing ſtrongly the Bellows, preſſes equally the Superficies of the Wine over the whole Length of the Piece, without cauſing the leaſt Agitation in the Wine; and the Force cauſes it to paſs down in the Pipe of Leather, and from thence into the other Caſk that is to be filled, where it riſes, becauſe the Air is driven towards the Bung-hole, which is open.

The Bellows puſh all the Wine in the Caſk to about ten or twelve Pints, or thereabouts; which is known when they perceive the Wine to hiſs in the Syphon; at which Time they take from the two Caſks the two Pipes that have been forced into them, and which are joined together by the Leather Pipe, and nimbly ſtop up the Hole at the Bottom of the Piece with a Bung of Oak made round, a little ſloping, and drive it with a Mallet: From the other Caſk that has been emptied, they pull out the Cannon or Pipe of Wood from the Fountain of Metal, and leave it to drain gently ſome Pints of clear Wine into a Veſſel that receives it.

They obſerve attentively, every Moment in a clear Glaſs, if the Wine be neat; and when they perceive but the leaſt Thing, without waiting till it appears foul, they ſtop the Fountain, and take it away immediately, and turn out into a Bucket that little Wine that remains in the Piece: That clear Wine which has drained out of the Fountain, they put into the Caſk that they have been filling: They uſe for this Purpoſe a Funnel of Tin, the Tail of which is above a Foot long, to the End that the Wine that paſſes through it, may not cauſe any Agitation in that of the Piece; and that there may not any Filth paſs into the Wine, there is, towards the Bottom of the Funnel, a Tin Plate pierced thro' with ſmall Holes, which prevents any Thing groſs from paſſing thro' into the Piece.

They put together into a ſeparate Caſk all the Remainders of the empty Pieces; preſently after they have emptied one, which they do in leſs than half an Hour, they waſh it with a Bucket of Water, let it ſtand to drain ſome Moments, and they fill it with another that is to be drawn off.

After the Wine has been emptied out of one Veſſel into another the firſt Time, they draw it off a ſecond Time, at the Time we have before-mention'd: Sometimes they are oblig'd to do it a third Time, to give it a lively Colour, if it has it not already; but four Days before they change the Caſk they give it a *Frizure*, as they call it, and put in it one third Part of ordinary Iſinglaſs.

The moſt experienced Perſons ſhift their fine Wines out of one Veſſel into another, as often as they change its Place, as well when they carry it down into the Vault, as up into the Cellar, according to the different Seaſons: I have known when, in four Years Time, they have drawn it off twelve or thirteen times; and they pretend, that this is that which preſerves and ſuſtains the Wine, and that it has been the finer and more delicate.

Their Opinion is, That the Wine is continually forming a fine Lee, which gives it the Colour; and that to preſerve it of a good White, it muſt be often ſhifted out of one Veſſel into another, if it be not put into Bottles; and that there is no Reaſon to fear that the Wine will be weakened by this Means, becauſe the oftener it is removed, the oftener you give it a new Vigour; and the oftener it is drawn off, the more lively and brilliant is the Colour.

And although I have ſaid, they ſhould not brimſtone their Caſks, they do not fail to uſe a Match of Brimſtone the firſt

Time that they change the Veſſels; they mingle a Piece of thick Linen Cloth in the melted Brimſtone, and they cut off a Bit for each Caſk of fine Wine about the Bigneſs of one's little Finger, and one as big again for every Piece of common Wine; they light it, and put it under the Bung of the Piece that they empty, before they have Recourſe to the Bellows; according as the Wine deſcends, it draws along with it a ſmall Scent of the Brimſtone, which is not very ſtrong, ſo as to make it perceiveable, and that only leaves what will give it a Livelineſs of Colour: The ſame may be done the ſecond Time, when they change the Caſk, if it has not taken the Scent the firſt Time, otherwiſe it ought to be drawn off the ſecond Time without a Match, to cauſe it to loſe the Scent of the Brimſtone, which it ought never to have.

The Wines that are thus clear and fine, keep well in the Caſk for two or three Years, and hold their Goodneſs in the Vaults and Cellars, but eſpecially the Mountain Wines that have a good Body: Thoſe of the *River* loſe their Quality in Wood, and they ought to be drank in the firſt or ſecond Year, or elſe they muſt be put into Bottles. This Wine will keep very well four, five, or ſix Years in Glaſs Bottles.

The Uſe of round Bottles is very common in *Champaign:* They having Plenty of Wood in the Province, have there ſet up very good Glaſs-houſes, which they ſeldom make Uſe of but in making theſe Bottles, which are about ſix Inches high, and four or five in the Neck. Theſe Bottles contain ordinarily a *Paris* Pint, or half a Glaſs leſs. They ſell them commonly for twelve or fifteen *Francs* a hundred. They have a certain Quantity in every Houſe. Before they enter upon a Piece of Wine to drink, they put it into Bottles, well waſh'd and drain'd, in order to have the Wine of one Piece equally good.

When they have a mind to draw off a Piece of Wine into Bottles, they put a little Syphon of Metal into the Cask, which is bent downwards to ſtrain it into the Bottle, under which there is a Tub or Bucket to catch the Wine that ſhall run over. They ſtop up every Bottle carefully with a good well-choſen Cork that is not Worm-eaten, but that is ſolid and cloſe. Theſe Sorts of fine Corks coſt fifty or ſixty Sols an hundred. There cannot be too much Care taken in the chuſing Corks, leſt the Wine ſpoil in ſome of the Bottles, when the Corks are defective; therefore great Care ſhould be taken in the chuſing them, when you would draw off fine Wines into Bottles, whether it be for keeping, or to be ſent abroad.

When Bottles are uſed that have been made uſe of before, they ſhould be waſhed with Leaden Shot and a little Water, to fetch off the Filth that ſhall remain on the Bottom of the Bottles; but it is much better, in the room of them, to uſe ſmall Nails, becauſe they perfectly take off all that which ſticks to the Glaſs.

When all the Bottles, that ſuffice to empty one Caſk, are filled, they tie the Mouth of the Bottle over to the Neck with a ſtrong Packthread; and if it be a fine Wine, they commonly ſeal it with *Spaniſh* Wax, that the Wine may not be changed, nor the Bottles, by the Domeſticks; and ſome Perſons have their Coats of Arms made on the Bottles, which does not enhance the Price above thirty Sols *per Cent.*

When all the Bottles are well ſtopp'd, ty'd down and ſeal'd, they ought to be ſet either in a Vault or Cellar, upon Sand two or three Fingers Depth, and laid ſide-ways, leaning againſt one another; when they are ſet upright, they form a white Flower upon the Wine at the Top, in the ſmall empty Space that is between the Top of the Mouth of the Bottle and the Wine; for the Bottles ought never to be filled up to the Top, but there muſt be left a ſmall empty Space of about half an Inch between the Wine and the End of the Cork.

If this was not done, the Wine would ſet a working in the different Seaſons of the Year, and break a great Number of Bottles; and it does, notwithſtanding, break a great many, in ſpite of all the Caution that can be taken; and more eſpecially when the Wine has a great deal of Heat, or is a little tart.

In ſome Years the Wine grows ropy in the Bottles, even in the Vaults, ſo as to rope when it is pour'd out, as if it had Oil, ſo that it cannot be drank. This is a Malady that ſeizes the Wine that has ſtood ſeveral Months without being removed from one Place to another: If it be ſet in the Air, it will loſe more of its Ropineſs than it will if left in the Vault: It will recover itſelf in eight Days, if ſet in a very airy Granary, better than it will oftentimes do in ſix Months in a Vault.

When one is obliged to drink a ropy Wine, if he ſhake the Bottle ſtrongly for the ſpace of half a Quarter of an Hour, and then uncork it immediately after he has done ſhaking it, the Bottle being inclin'd a little on the Side, will caſt out preſently half a Glaſs of Froth or Scum, and the reſt of the Wine will be drinkable, whereas otherwiſe it would not be ſo.

For about twenty Years laſt paſt, the Guſt of the *French* has been determined for a frothy Wine, and this they uſed to love, as one may ſay, even to Diſtraction. They have begun a little to come off from that for the three laſt Years. Their Sentiments are much divided as to the Opinion of this kind of Wine: Some believe that it proceeds from the Force of the Drugs that they put in it, which makes it froth ſo ſtrongly: The others attribute it to the tartneſs of the Wines, becauſe the greateſt Part that do froth are extremely tart: Others attribute this Effect to the Moon, according to the times in which theſe Wines are bottled.

It is true, there are a great many Wine Merchants, who ſeeing the great Fondneſs that there is for their frothy Wines, oftentimes put in Alom, Spirit of Wine, and Pigeons Dung, and a great many other Drugs, to make it froth extremely; but it is certain, by Experience, that the Wine froths when it is any Time bottled from the Vintage to the Month of *May:* There are ſome who pretend, that the nearer the Vintage-time the Wine is produced, when it is bottled, the more it froths. Many do not agree to this Opinion; but nothing is more certain, than that there is no Time in which the Wine froths more, than about the End of the ſecond Quarter of the Month of *March*, and this always happens towards the *Holy Week*. There does not need any Artifice at all, one may always be ſure to have Wine perfectly frothy, when it is bottled from the 10th to the 14th of the Month of *March*; of this there is ſuch reiterated Experience, that it cannot be doubted.

It is good to know, that the Wine does not froth preſently after it is put in Bottles. It muſt be at leaſt ſix Weeks, and ſometimes ſix Months before it froths well. If it is to be tranſported, you muſt give it near a Month of the Vault, eſpecially in the *Summer*, to recover its Remove.

But as Wines (eſpecially the Mountain Wines) are not ordinarily bottled in the *Holy Week*, becauſe they are then too green, or have too much Hardneſs, eſpecially if the Year has been cold and moiſt, or too much Liquor expreſs'd, if the Year has been hot: the moſt ſure and advantageous Way to have exquiſite Wine, that is perfectly frothy, is not to bottle it till the Riſe of the Sap of *Auguſt*. It is certain by Experience, that it froths exceſſively when it is bottled from the 10th to the 14th of *Auguſt*; and as it then loſt either the Tartneſs or Greenneſs of its Liquor, one may be aſſured in either Bottles to have the ripeſt and moſt frothy Wine.

There has been another Experiment try'd, which is, not to bottle the Mountain Wine till the *Holy Week* of the ſecond Year, that is, eighteen Months after the Vintage; and it has been found, that it froths ſufficiently, but leſs by half than that which has been bottled in the Riſing of the Sap of *March* the Year before.

It is not believ'd that the River Wine, which has a leſs Body than that of the Mountains, can froth ſo much in the ſecond Year.

When one would have Wine that will not froth at all, it ſhould be bottled in *October* or *November*, the Year after the Vintage: If it be bottled in *June* or *July*, it will froth ſlightly; though but a little, if any thing at all.

To find in the Wine of *Champaign* all the Merit that it ought to have, it ſhould be taken out of the Vault not above half a Quarter of an Hour before it is drank, and it muſt be put into a Bucket, with two or three Pounds of Ice; the Cork ſhould be opened, and put in again lightly; which, if it be not done, the Wine will break the Bottle, or will not grow cool if it were not unſtopped, and it would evaporate itſelf, if it remain'd quite open. When the Bottle has been half a Quarter of an Hour in this Ice, it muſt be taken out, becauſe the Ice would otherwiſe chill it too much, and make it loſe its Briſkneſs. This Wine will be excellently good, and of a delicious Flavour, when it has been a little affected by the Ice; but great Care muſt be uſed that it may not be either too much or too little.

As theſe Wines, eſpecially thoſe of the ſame Year, work continually in the Vaults and Cellars, and ſtill more in Bottles than in the Pieces, according to the different Seaſons, and the divers Impreſſions of the Air, it ought not to be ſurpriſing, if the ſame Wine, eſpecially the new, oftentimes appears different in Taſte. We find a Wine potable in *January* and *February*, which will ſeem hard in *March* and *April*, becauſe of the riſing of the Sap, which agitates it more; the ſame Wine in *June* and *July* will appear intirely ſoft, and in *Auguſt* and *September* we ſhall find it hard again, which one ſhall not be able to perceive any Thing of during the preceding Months, becauſe the riſing of the Sap in *Auguſt* will put the Parts in a great Motion. This Effect Motion will have on the River Wines of the Year; but oftentimes the Wines of two Years from the Mountains will appear more mellow, more or leſs exquiſite, more or leſs forward, according to the different Motions it has received by the different Impreſſions of the Air, which will vary more ſenſibly in the different Seaſons of the Year.

There ought to be a very great Attention to keep the Wine continually in cool Places; nothing does it more Hurt than Heat: It is therefore of the greateſt Importance to have good Cellars, and excellent Vaults. No Part of the World has ſo good Vaults as thoſe in *Champaign*, which is the Reaſon it is ſo difficult to find any where elſe ſo good Wines as thoſe of this Province.

Thoſe who would lay up a Stock of Wine, and are able to keep it two or three Years, or whoſe Buſineſs it is to ſend it into other far diſtant Provinces, or to foreign Countries, ought to chuſe the Mountain Wine; for as it hath more Body, it will better bear Tranſportation, than thoſe of the River; and beſides, the *Engliſh*, the *Flemings*, the *Dutch*, the *Danes*, and the *Swedes* deſire theſe ſtrong Wines that can bear the Tranſportation, and hold good for two or three Years, which the River Wines will not do.

The moſt noble River Wines are thoſe of *Auvillers*, *Ay*, *Epernay*, *Pierry*, *Cumieres*: Thoſe of the Mountain are, of *Sillery*, *Verzenay*, *Taiſſy*, *Mailly*; and above all, thoſe of *St. Thierry* have the moſt Reputation. The laſt has for a long Time had the greateſt Name, and been the moſt called for; and one may venture to ſay, that it comes nothing behind the beſt Wines of *Champaign*.

By all the Obſervations which have been made on what is practiſed in this Province, in cultivating and ordering the *Vines*, and in fining off the Wines, in bottling and carrying them up and down into Cellars and Vaults, and from Vaults to Cellars, it will be found that even Perſons of good Taſte, in the Provinces of *Burgundy*, *Berry*, *Languedoc* and *Provence*, who are yet very curious and delicate in making Wines, eſpecially for their own Tables, know not ſo well how to bring it to Perfection, as thoſe who are accuſtomed to make it in this Province; for though their Wines have not the Tartneſs of thoſe of *Champaign*, yet they are able to make them more clear, fine and light. They might therefore try if they would not be preſerved better in drawing them off from their Lee, than in letting them lie on it, according to their uſual Cuſtom, which ſome are of Opinion is abſolutely wrong. They ſhould chuſe and pick, in the Freſh of the Morning, their fineſt black Grapes, and thoſe whoſe Berries adhere the leaſt together, becauſe they are the ripeſt; and they ſhould obſerve to leave as little Stalk to them as may be; and with regard to preſſing, which they are uſually faulty in, they ſhould immediately, as ſoon as carry'd, trample every Load of Grapes ſucceſſively as they are brought in; and collecting the firſt, muſt put it in new Caſks of a leſs Size; and when they have finiſhed treading the Remainder of each Carriage, they ſhould put them into the common Vats; but let them not remain there ſo many Days as they are generally uſed to do, that ſo their common Wines may be thinner and leſs ſtrong. By this Management, they might make four, five or ſix Pieces of fine Wine, more or leſs, according as they ſhall find it good; and then they ſhould take the ſame Care as has been ſaid thoſe of *Champaign* do: And if they would be content now with a leſs Produce, they would have a far greater Quantity the following Years, and would be continually bringing it to a ſtill greater Perfection, as they improved more and more in Experience. In thoſe Countries where they can conveniently have Preſſes, they ſhould make them.

Their Wines would be more delicate, more light, and leſs colour'd by this Attention, and with half the Fining, would be better for Tranſportation, in drawing them from the Lee, and eſpecially if they are put into Bottles.

There are ſome Diſtricts or Cantons in the South Provinces of the Kingdom, where the Earth is very fine, which would produce exquiſite Wine: It would not, indeed, have the Tartneſs as thoſe of *Champaign* have, but then it would have another very pleaſing Flavour that thoſe have not.

All theſe Obſervations which we have made will be of great Uſe to thoſe Perſons who would improve their Wines, or deſire to drink delicious Liquor. But ſuch Perſons muſt remember, that they ought above all this to ſtudy to have good Vaults; and thoſe which are cooleſt in the *Summer*, and warmeſt in the *Winter*, are ever the beſt.

It may ſeem to many Perſons in this Country, that we have been too prolix in the Account we have given; but theſe Obſervations are not deſigned for thoſe who are acquainted with the Practice already; but for ſuch Perſons as are wholly ignorant of theſe Things, and who are ſo far from taking any Pains in the ordering their Wines, that it is a Pain to them to conceive the greateſt Part of thoſe Things which I have taken Notice of, to be neceſſary; and who cannot be perſuaded but that they obſerve every Thing requiſite to the proper Management of Wines as exactly as thoſe of *Champaign* do.

Nothing is ſo aſtoniſhing as the Indifference there is in the remote Provinces, where Wine is ſo abundant, both in the Culture of the Vineyards, and the Choice of the *Vines*, as alſo in the Manner of Making, and the Management of the Wines. The Want of Preſſes ought not to be allow'd as a juſt Excuſe for their not making their Wines entirely white: But of this anon.

They practiſe nothing in *Champaign* which may not be perfectly imitated in other Places; the drawing off the Wines, the Manner of fining them, and putting them in Bottles, *&c.* is all equally poſſible, and alſo eaſy. Many Perſons might enrich themſelves, if they would ſet themſelves about it, with the Help of theſe obſervations, and of thoſe they might make themſelves, to bring their Wines to Perfection; and inſtead of ſelling them for one or two *Sols per* Pot, as they ordinarily do, they might ſell them for upwards of eight or ten. They would have the Satisfaction of augmenting their Income, and ſee their Wines ſought after, and they would be able to ſell them not only at Home, but alſo to tranſport them into foreign Countries; becauſe their Situation is more favourable to ſend them by Sea than that of the *Champaignois*, who are obliged to tranſport theirs upon Waggons, and by Rivers, into *Germany*, and the fartheſt Parts of the North.

Perhaps ſome Criticks will object the Difference of Climates, which will not permit the ſame Culture of the ſame Plants, which by their different Qualities do require particular Managements. This Way of Reaſoning might have Place, if I had pretended to ſpeak to a People who ſtudied to order their *Vines* with great Attention, and to give them a Fineneſs; but I have it chiefly in View, as I have had in collecting theſe different Obſervations, to inſtruct thoſe People who are entirely ignorant of the Method uſed in thoſe Countries where they are accuſtom'd to make excellent Wines, as well by reaſon of the Goodneſs of the Lands, and the Warmth of the Climate, as by the Induſtry of thoſe who inhabit them.

In *Champaign*, where their Grapes do not ripen but with Difficulty, becauſe their Country is cold, they make the pale Wines, and the white, the Wines truly grey, which are a little colour'd, and the Velvet Wines: Why can't they make all theſe Sorts of Wines in *Berry*, in *Burgundy*, in *Languedoc*, in *Provence*, &c.?

The Warmth of the Climate will not permit Wines to be made perfectly white with black Grapes; they will have a little Colour, and they will not thence be leſs exquiſite than thoſe they have made theſe fifty Years in *Champaign*, and, in the main, are better in Taſte, and better for Health than thoſe Wines that are perfectly white, which cannot be uſed but after Dinner.

The whole of my Intention in publiſhing this Collection of my Remarks, is to oblige thoſe who deſire to be able to give a greater Agreeableneſs to the Wines that they make for their own drinking, and to animate thoſe who have hitherto thought that a greater Excellence cannot be given to the Wines in their Diſtricts or Cantons, to take more Pains to bring them to Perfection; which will contribute greatly to raiſe the Value of the Commerce of Wines in the remote Provinces.

A DISSERTATION *on the Situation of* Burgundy, *and the Wines that it produces. By Mr.* Arnoux.

The Town of *Beaune* is the Centre of *Upper Burgundy*; it is ſituate in a Territory the moſt fertile and ſerene in *France*; it is all round encompaſſed with Cities, among which is *Autun*, the ancient Capital of the *Gauls*; *Dijon*, the Capital of the Dutchy of *Burgogne*, *Nuis*, *St. Jean de Leaune*, *Verdun*, *Seuree* or *Bellegarde*, *Chalon* on the *Saone*, *Arnay le Duc*, *Sanlieu*, *Flavigny* and *Semeur*. *Beaune* is placed almoſt in the Middle of theſe Towns, which are not above eight, nine, twelve, twentyone, or twentyfour Miles at the fartheſt, to be, as it were, a Nurſe to them all, in diſtributing plentifully amongſt them the Liquors which it produces.

All the Learned are agreed unanimouſly, that it is the ancient *Bibracte* of which Mention is made in *Cæſar*'s Commentaries, in theſe Terms; *Poſtridie ejus Diei*, &c.

Cæſar not having above two Days Proviſion for his Army, and not being above thirteen Miles at the moſt from *Bibracte*, the biggeſt, richeſt and moſt fertile City of the *Heduans*, thought proper to march thither to procure Proviſions for his Troops, and that is the Reaſon he quitted his way to *Switzerland*, and came to *Bibracte*. *Com. Cæſ. Lib. de Bel. Gal.*

Cæſar ſays, in another Place, That *Bibracte* among the *Celti* of the *Heduans*, is the largeſt and moſt fruitful City of the *Gauls*, and that which has the greateſt Authority among the *Heduans*, in which he called a Council of war, iſſued Laws, and where he paſſed the *Winter* with his Troops. He ſays alſo, That this Town is ſituate at the Foot of a Hill, and that it is not far from the Town of *Autun*. All this appears true, as well from the Fertility of the Country as its Situation and its Diſtance from *Autun*, which is not above twentyfour Miles.

Nevertheleſs, *Bibracte* having been the Theatre of many Wars, and having been ruined by ſeveral Sieges, *Beaune* has been built upon its Ruins, and has taken its Name of *Bellona*, becauſe its Inhabitants were always trained up in Military Diſcipline; and afterwards in *Latin* was named *Bellona*, and ſince that *Belna*.

The ſeveral Wars which have ravaged this Country, have not left any Monuments of this Antiquity ſo worthy of a Remark, as are to be ſeen in the precious Remains of that Sort in the Town of *Autun*.

And if I might be permitted to make here a ſmall Digreſſion, I would entertain the Reader with the Antiquities which I have view'd during the long Reſidence which I made there.

The fineſt Piece of Antiquity that is to be ſeen there, is an Amphitheatre of a vaſt Extent, the Traces and Footſteps of which, although worn by Time, are yet remaining in a Semi-circle, and do extend a full third Part of a Mile in Length; there are to be ſeen the Caverns, where the Lions, Tygers, and other fierce Beaſts were ſhut up: And there are ſtill Parts of the ancient Walls remaining, which ſhew that the Circumference of this Town was ſix or ſeven Miles; the Place, which is in the Middle of the Town, is four times as big as the Square of *St. James*'s, where the Troops are exerciſed in Arms, and which is called the *Field of Mars:* The Tomb of *Divitiacus*, which is of a round Form, comes out of the Ground like a ſhapeleſs Lump, and ſuddenly growing narrower towards the Top, appears as if broken. This Maſs, which has neither going in or out, is elevated on a riſing Ground, worn out by Time, and appears like a Block; the Sand, the Lime, and the Stones are become all the ſame, by the Rains and the Air which have calcined them: This Pyramid has ſubſiſted above two thouſand Years.

There remain of this ancient City two Gates, which have held out obſtinately againſt Time that conſumes all that Mortals would eternize: The one, raiſed upon four maſſy Piles, encircled with Baſs Reliefs and Hieroglyphicks, forms three Centres crowned in one Range of Architecture of fluted Stones, which are all of an extraordinary Height, in which no Joints nor Cement can be perceived. There alſo yet appears one half Part of the Temple of *Janus*, the Mount and the Foreſt of the *Druids*, the Mount *Joüy*, or *Jupiter*'s Mount; and in digging the Earth but never ſo little, or in ploughing, there are found Urns and Medals.

But to return to the Town of *Beaune:* This Town cannot pretend to glory in theſe ancient Remains of Antiquity, which the Air conſumes, and Time reduces to Duſt; it only glories in its good Wines, which every Year brings to the Citizens new Riches: However, it has been within an Age paſt a ſtrong Place, and is ſtill ſurrounded with a large Ditch which runs into the River *Burgoiſe*; this takes its Source at about half a Mile from one of its Hills. It is alſo encompaſſed with a Rampart, flank'd with ſome Towers, and five great Baſtions; the Ditch, which encompaſſes the Town, is above a Mile and an half in Circumference: The Citizens there enjoy almoſt continually a pure Air, and a clear Sky, being equally about an hundred Leagues off from the *Mediterranean* and the *Ocean*. The Waters are, as one may ſay, in Suſpenſe, when it is about to determine its Courſe: There is alſo a great Body of Water in its Neighbourhood, which is ſeen in all the Charts of *France*, under the Name of the *Pond of long Extent*. It is the Opinion of ſome Perſons, that this partakes of the Waters of both Seas.

This Town can count fourteen or fifteen thouſand Inhabitants, of which the fourth Part are employ'd in cultivating the Vineyards; another fourth Part in careleſsly exerciſing ſome Profeſſions that they are ignorant of; and the other half in enjoying the Pleaſures of a ſoft, idle and delicious Life. The Gout and Sickneſſes are baniſh'd from theſe Walls. From theſe Hills, that produce ſuch exquiſite Wines, iſſue out Fountains of Ice, and little Rivers as clear as melted Cryſtal. Theſe Waters iſſue out from the Earth in a Line oppoſite to the Perpendicular, bubbling up, and puſhing out of the Earth on high Globes of Rock-cryſtal, which keep their ſpherical Figure till they are at the Superficies.

The Purity and Lightneſs of theſe Waters are the Cauſe that they here eat the lighteſt and beſt Bread in *France*. The Cattle are not ſo large nor fat as thoſe of *England*, but they have a more delicious Taſte. The Game there is moſt delicious; but above all, thoſe who inhabit the Hill, where grow *Thyme* and *Marjoram*, and in ſome Places *Broom:* And in the Month of *September*, a little Bird, bigger than a Linnet, and ſmaller than a Lark, comes to furniſh the Inhabitants of theſe Hills with the moſt dainty Diſh which can come to a King's Table: This is the *Wheatear*, which comes out of the Wood, when the Grapes are ripe; they get among the Vineyards, and fatten themſelves with the Grapes, which they pick with their ſharp-pointed Bills, from which they ſuck the Juice, and with which they make themſelves downright drunk. This Bird comes into the Vineyards ſmall and lean, and in a little Time grows fat to the very Extremity of its Wings, to that Degree, that they cannot fly above eight or ten Paces, by reaſon of the Weight of that Bulk which they have acquired upon the Vine-branches: So that, in order to render them light to fly, they ought to take the Counſel of *Horace*, which he makes the Weaſel give the lean Fox, that had entered thro' a ſtrait Hole into a Barn of Corn;

> *Macra cavum reptes arctum, quem macra ſubiſti.*

It is pretended, and I do believe, that this little Bird is the moſt delicious Diſh in *Europe*; I have ſeen a great many in *England*, and alſo kill'd them out of Curioſity; but as they have not the ſame Liquor and the ſame Feed that they have in *Burgundy*, they have nothing of the ſame Taſte.

Beaune is remarkable for the Magnificence of its Hoſpital, which was there founded and built by Chancellor *Rolia*. *Philip* the Good, Duke of *Burgundy*, being informed that his chief Miniſter had attempted ſo great a Work of Piety and Charity, laugh'd, and ſaid, ſince his Chancellor had done ſo much for the Poor in his Life-time, it was but juſt that he ſhould lodge them, and feed them after his Death.

The Hills of *Upper Burgundy* which produce the Wine, the only Wine which one can or ought to call *Burgundy* Wine, do not extend farther than from *Dijon* to *Chalon* upon the *Saône*; yet we ought not to reckon thoſe Vineyards to be in Perfection but from *Chambertin* to *Chagni*, about twenty-four Miles in Extent: For the *Vines* at *Dijon* and *Chalon* do not enjoy thoſe Climates which produce thoſe Wines that are fit to be tranſported into *Great-Britain*, the Circles of the *Empire* and the *Low Countries*, as thoſe which are confin'd within the Limits, that I ſhall mention as exactly as I can, without being apprehenſive of paſſing under any Cenſure upon this Account.

The ſame Row of Hills in the ſame Situation, and having the ſame Aſpect of the Sun, extends itſelf almoſt as far as *Lyons*, and all thoſe little Mountains are wholly cover'd with *Vines*; but the lands are leſs fine, and leſs light at *Chalons*; are heavier at *Tornus*, and coarſer at *Macon:* This alters the Form of the Productions of theſe little Hillocks, which, notwithſtanding they have the ſame Arrangement, and the ſame Situation, produce ſo different Liquors.

All thoſe little Vallies are link'd one to the other to the Eaſt Aſpect of the Sun, and form the Figure of an unbent Bow, and have oppoſite to them a Row of Mountains of the like Figure, but a great deal higher, which appear or ſeem to join them, although they may be fifteen, twenty, thirty, and ſome ſixty Leagues off, and forming an oval Figure, contribute to make the fineſt Proſpect in the World. This Oval muſt have more than one hundred and fifty Leagues in Circumference.

From theſe Hills of *Beaune* all the oppoſite Mountains are ſeen, and they are thoſe of *Switzerland*, the *Franche Compté*, and Mount *Jura*, of which *Cæſar* ſpeaks, at this time call'd *Mount St. Claude*, thoſe of *Savoy:* Beyond theſe is a frightful Void, and of an immenſe Length, and Mount *St. Bernard* riſes into the Clouds, always cover'd with Snow in the moſt violent Heats of the *Dog-days*; and although it be ſixty-five Leagues off from *Beaune*, it is ſeen diſtinctly without the Help of any Glaſs which ſhall bring it nearer to the Spectator's Eye.

This perfect Oval forms a Plain of the ſame Figure, to which theſe Mountains that environ it, ſeem to ſerve for Walls and Ramparts: This vaſt Plain is water'd by the

Saône, which *Cæſar* calls *Arar*; and by the *Doux*, which he calls *Alduaſdubis* in his *Commentaries*, which has its Source at the Foot of Mount *Jura*, paſſes by *Beſançon* and by *Dole*, and caſts itſelf into the *Saône* at *Verdun*: There are alſo a thouſand pretty Rivers and Streams, which, after many Turnings and Windings, loſe themſelves in the *Saône*.

This great Plain, which is at the Centre of the Continent, is ſo even, that the *Saône* which runs through it, by its gentle Courſe, deceives the Eyes of thoſe who look upon it, it being difficult to diſcover which Way its Stream glides; *Cæſar* himſelf was ſurpriz'd at it, as he declares in *Lib.* I. of his *Commentaries*.

The *Saône* is a River that ſeparates the *Heduani* and *Sequani* (i. e. *Bourgogne* from the *Franche Comté*) and flows into the *Rhone* with an incredible Gentleneſs, that one cannot diſtinguiſh by the Eye which Way its Waters run.

This is a vaſt Plain, ſo fertile and even, that all the Kings of *France* are wont to aſſemble their Armies there, when they have a Mind to ſhew the Encampment of all their Troops to the Queens, and the Ladies of the Court.

Behind the firſt Row of Hills that produce ſo good Wines, there is nothing to be found but Hills and Vallies: The Hills that are the leaſt diſtant, are all planted with Vineyards, and theſe Situations are call'd *Backward Hills*: In the hotteſt Years, when the Rains are leſs frequent, the Grapes there make a very good Wine, but it never has the Perfume of the Wines produc'd by the forward Hills.

The Plain of this Oval is in part cover'd with Wines, fertile in all Sorts of Grain, embelliſh'd with vaſt Meadows, where a thouſand Streams play in their different Windings, adorn'd with fine Foreſts inhabited with Stags, Wild Boars, and, above all, with Roe-bucks, which are there very delicious, and agreeably furniſh the Gentry with the Divertiſements of Hunting.

A great Part of theſe Lands are planted with Trees in Form of Orchards, which produce without Culture excellent Fruit, which when they have been once grafted, it is enough, the Sun and the Earth do the reſt: The *Peach-Trees*, which throughout ſympathize with the *Vine*, do there make upon the Banks a fair Foreſt; and the Branches of theſe Trees grow thinly, and the Leaves being narrow, they don't hinder the Sun from darting his Rays on the *Grapes* to ripen them: The *Peaches* which they produce are of a Figure and a Colour that would not anticipate one in their Favour; nevertheleſs, when one has taſted of them, it ſeems to the Palate to be a Fruit made of Wine and Sugar.

It ought not to be forgotten, that when the Sun is riſen above the Mountains of *Savoy*, there is a Proſpect of the Hills of *Burgundy*, where it ſhines during the whole Day; and in ſetting behind the Hills of *Beaune*, darts its Rays upon the Mountains of the *Franche Compté*, which lie oppoſite to it, and there, in going down, ripens very excellent Wines, as thoſe of *Arbois*, which are ſo well known throughout *Europe* for their Excellent Qualities.

Before I begin to ſpeak of the Quality of the Wines of *Beaune*, it will be proper to give an Account of the Manner in which they there cultivate their Vineyards, and make their Wines: For altho' *Burgundy*, by the Goodneſs of its Soil, and its Expoſure to the Riſing Sun, does naturally produce delicious Grapes, yet the Manner of cultivating their *Vines*, and of making their Wine, contributes much to its Goodneſs.

During the *Winter*, the *Vignerons* employ themſelves in examining the Earth of their Vineyards; and by ſome Loads of Earth conveniently laid, which they carry thither, they fatten the Places which appear to be worn out, and ſeem to require Aſſiſtance to produce the better Grapes, which happens, however but very ſeldom. Then they take Notice of thoſe Places which are void of *Vines*, whether they are declining by Age, or do not appear to promiſe Grapes; and they make large Trenches from a Foot and a half to two Feet and a half long, and a Foot deep: If the Earth is too lean, they put in half a Foot of good Earth, and ſometimes a little old well-rotted Dung, but generally ſpeaking, they put in nothing at all; and taking one or two Branches, they bend them down into each Trench, and cover them afterwards intirely with the proper Earth of the Vineyard, in ſuch manner that you may ſee the two Ends of the *Vine-branch* bent come out of the Earth; to wit, that by which it holds by the *Vine*, and that of the other End which comes out of the Trench where they have bent it, about three or four Finger Lengths. They make a great many of theſe Trenches in a Vineyard, that they may be always ſupplied with young *Vines* that will produce a good Plenty of Grapes: For it ought to be obſerved, that this *Vine-branch* bent down in a Semi-circle in this Trench, which is a Shoot of the preceding Year, having its Pores open, takes in two Sorts of Nouriſhment; the one from the *Vine* to which it is united, and the other from the Trench in which it has been bent, in which it takes Root. Theſe are what they call *Provins* or *Layers*.

They produce abundance of Grapes, which are commonly firſt ripe, well nouriſhed, large and well reliſh'd, but their Juice is not ſo good as that of the Grapes of the old *Vine*: The Phyſical Reaſon is, that the nouriſhing Juice has not been ſo well filtred in paſſing through thoſe Layers, whoſe Pores are very open, as in paſſing through the Pores of the old *Vine*, whoſe Pores are more cloſe and leſs ſpungy.

They dig with a Spade the Vineyard ordinarily three times a Year, that is, about the End of *February* or Beginning of *March*, when they give it the firſt time; and it is in this Month of *March* or about the End of *February* that they prune their Vineyards.

And in this conſiſts the Addreſs and Skill of the *Vigneron*, for he ought to make a right Choice of thoſe fine Branches that he is to prune, and of the Joint where he is to cut the Shoot, as well as that which he is to cut intirely off.

See here what I have ſeen practiſ'd by the *Vignerons*. Of four or five Sprigs, the Shoots of a Year, belonging to the ſame Stock or *Vine*, they leave but one or two of the beſt made, which they cut off to the third or fourth Joint at moſt.

The ſame they practiſe on the *Vines* on the Hills, which produce the fineſt Wines; for as to the *Vines* on the Backſide, or of the Plain, they cut them to the ſecond or the firſt Knot, for theſe *Vines* put forth too many Twigs: But as this is an Art of which it will be difficult to give the Precepts, becauſe the manner of cutting the *Vines* is different, according to the Ground, the Nature of the *Vine*, its Quality, Expoſition, and Nearneſs to the Sun, I will go on with my Diſſertation.

When the *Vine* is cut, they place *Vine* Props, to which, to the Height of half a Foot above the Earth, they bind the Branches of the *Vines* in an horizontal Manner; and afterwards, when the Buds or Eyes are open'd, and have put forth Shoots in Length about a Foot and a half, they embrace them, that is to ſay, they bind them to the Props which ſuſtain the *Vines* which produce them. Theſe Props are of the Height of three or four Feet, and the Thickneſs of an Inch, are ſtruck into the Ground without any Arrangement or Order, at the Diſtance of a Foot more or leſs the one from the other, according as the Vineyard is more or leſs furniſh'd with *Vines*.

Nevertheleſs the End of the Shoots which are there bound horizontally, as one may ſay, look all to the ſame Side.

This Manner of placing the Props without Order, is of great Conſequence, that is, that one Branch may not be covered by the Shadow of another but as little time as may be; and that if the Root comes to ſome Grapes, they may not be able to communicate it to others. This Manner is contrary to that of the *Engliſh*, who plant their *Vines* in Hedges; and thence it is that the one hinders the Sun from ſhining upon the other, and of Conſequence that hinders the Ripening of the Grapes.

That is the moſt dangerous Seaſon for the *Vine*, and the moſt delicate, when there has been a North Wind, and that has caus'd a ſmall white Froſt: If the Sun comes to appear in the Morning, it dries and burns all the young Leaves, the Buds and the Grapes, after the ſame manner as if Fire had been there.

It is for this Reaſon that the Friars in *Burgundy* have recourſe to Prayer at this Time more than at any other; and that after there has been calm and cold Nights, the ſuperſtitious Peaſants run to the Churches, and ring the Bells with all their Might. Whether it be that they imagine that God has any regard to this Work of Religion, or that the Agitation that they make in the Air, may, in ſome ſort, warm the Air again, or change the Wind: But however it be, they do at this Time ring the Bells with ſuch Violence, that there is no ſleeping: During which Time, the Prieſts and Monks are buſy in reading in the Churches the Paſſion of our Saviour, according to the Goſpel of St. *John*; and for this Occupation, they make a Collection among all the Preſſes at the Time when they make their Wine, and every *Vigneron* is oblig'd to give them a certain Quantity of Wine, and that by an Order of Parliament at *Dijon*.

When the Vineyard has eſcap'd the Danger of the Froſt, they dig afreſh; and this they call [*biner*] the digging of the Vineyard the ſecond time; after which the Grapes ſoon begin to flower, which ſpread a ſweet Savour all over the Country; and is the Time when all the Wines which are in the Tuns in the Vaults, though never ſo deep, if they are upon their Lee, without having been drawn off or clarify'd, rify'd, work, ferment, grow thick, and cover their Superficies with ſmall white Flowers like Snow; a Thing difficult to be explain'd by Philoſophers, in this Queſtion, in Phyſicks, when they demand *Utrum detur actio in diſtans?*

It muſt be obſerved, that all the *Vines* of the good Hills of *Burgundy*, paſs from their Flowers to the Grape; that is to ſay, that the Flower of the Grapes change into Berries in the Space of twenty-four Hours; and if during that Time, there happens a cold Fog, or a cold Rain, their Flowers, inſtead of turning to Grape, fall, and the ſecond Peril is no leſs dangerous than the firſt, when that happens: The Term that they make uſe of to expreſs it, is, to ſay the *Vines* are [*coulè*], *i. e.* drop their Grapes.

At the End of *June* or Beginning of *July*, is the Time when the *Vine* changes from the Flower to Berries; after which, the *Vine* has nothing to fear but the Hail, or a too great Drought. Aſſoon as ever the *Vignerons* ſee the leaſt Cloud to riſe upon the Horizon, and the Air ſeems to threaten the leaſt Storm, they have Recourſe to their Prieſts and their Bells, and their *Pater-noſters*, which they would not recite but for Fear that the People would riſe againſt them if Hail ſhould happen during that time that they were not at their Prayers.

The Reaſon that they are ſo much afraid of the Hail in *Burgundy* is, becauſe the Vintage is all the Dependance of the Inhabitants; and that the Grapes being ſmitten by this Scourge, give to the Wine, in ſome meaſure, the ſame Taſte and the ſame Scent which Lightning ſpreads on the Places where it falls, a Scent which is impoſſible to take away.

As to Drought, it is not only to the Bells, or to the Prieſts that they have Recourſe, but to one or two Stone-Buſts in two Villages about ſeven or eight Miles from the Town of *Beaune*; one of which Idols is known, and worſhipped under the Name of *St. Revereen*, and the other under the Name of *St. Marguerite:* They aſſemble together, and go in Proceſſion to ſearch in Triumph for this Stone, which they carry ſolemnly to a Church in the Town. All the Prieſts go in Proceſſion, followed by the Pariſhioners of which they are Curés, and they offer their Incenſe and their Prayers, rub their Books and their Chaplets againſt theſe extraordinary Figures; and oftentimes it happens to rain in this Conjuncture, which does not a little contribute to keep up this Superſtition in the People.

It is in *July* that they dig the Vineyard the third time; this they call *Thirding*. There are many Years in which they dig their Vineyards the fourth time, and this is in the Month of *Auguſt* that they give it this fourth Digging; but they take great Care to dig the fourth time when the Seaſon is not too hot or dry; or on the contrary, to defend the Grapes from the Heat of the Sun, they let the Graſs grow in the Vineyards; this ſhades them, and hinders the Vapours of the Earth from burning the Grape.

A Month before the Vintage, the Magiſtrates of *Beaune*, accompanied with many experienced Judges and Perſons of Probity, make three Viſits to examine the Maturity of the Grapes; and at this third Viſit and Examination, they decide the Day of gathering the Vintage. No private Perſon dares to cut in his own Vineyard one ſingle Baſket of Grapes upon Pain of Confiſcation and a conſiderable Fine; for if it were permitted to each particular Perſon to gather his Vintage according to his own Fancy, and his particular Opinion, and according to his Taſte, there would be Wines too green ſent abroad into other Countries, to the Diſhonour of *Burgundy*, and to the Diſcredit of the Wines.

And alſo for Fear that any Vapour ſhould ſpread itſelf over the Vineyards, for fifteen Days before the Vintage, they take Care not to burn any Straw or Hemp-ſtalks in the Streets, leſt the Smoak ſhould give any bad Taſte to the Grapes.

The Grapes being come to Maturity, the Magiſtrates give Notice a few Days before by a Trumpet to the Town, of the Time they have appointed and fixed for gathering the Vintage. *Volnet* begins firſt, a Day before *Pomard*, and afterwards all the little Hills gather their Vintage indifferently, for after the Town of *Beaune* has gathered their Vintage one ſingle Day, the Vintage is opened for all the other Vineyards on the Side of *Burgundy*. It will be ſeen by-and-by why *Beaune* decides the Vintage of *Volnet* and *Pomard*. It will ſcarce be believed, that all the Hills from *Chamberry* to *Chagny* ſhould have their Vintage gathered in the Space of four or five Days; and alſo it is ſcarce credible, what a vaſt Number of *Mountaineers* from every Part come to labour in this Work.

They gather the Vintage, perhaps, (and my Conjecture is founded upon more than twenty-five Vintages, which I have ſeen made) more than two thouſand [*Queües*] Tuns of Wine upon theſe Hills; and the *Queüe*, which is always divided into two Punchions, ſometimes into four Feuillettes, and very rarely into eight Cabillons, contains five hundred Bottles of Wine, or, to ſpeak more exactly, four hundred and forty Pints *Paris* Meaſure.

It will be proper here to obſerve, that in this great Extent, the Vineyards produce but one kind of Grapes, which they call *Noirons*; the Berries of which are black when they are ripe, and quite round: The Plain and the Backſides produce only a ſort of Grape, of which the Berries are bigger and a little longer, which they call *Gamet*.

Thoſe who would make excellent Wines, never cut the Grapes till after the Sun has dryed up the Dew which has fallen in the Night-time; for this Moiſtneſs, although it be but a rarefy'd Air, cools the Grapes, which being caſt into the firſt Vat, ſuſpends, and oftentimes hinders the Fermentation. Thoſe covetous Perſons that are more deſirous of the Quantity than the Quality, uſe not theſe Precautions; but, on the other hand, thoſe who would make excellent Wines, do not put into the ſame Vat any Grapes but thoſe of the ſame *Vine*; but almoſt all the particular Perſons who have an hundred Perches of Vineyard in different Cantons, mingle their Grapes the one with the other, becauſe the ſtrong helps the weak, and the good mends that which is worſe; and, in a Word, that they may make the Vat the larger. The Choice of the Cantons from whence the Wine is produced, depends on the Diſcernment that the Courtiers or Commiſſioners ought to have, when they taſte the Wines that they would ſend into other Countries, and that which the *Engliſh* Gentlemen ought to recommend to their Commiſſioners who furniſh them with Wine for their drinking.

The Grapes being put into the fermenting Vat, throw up a great Scum, which, by the Agitation, make to the Ears a continual trembling a little cluttering, and ſpread abroad ſuch a Scent, that is capable of intoxicating, and perfumes the Houſes, and ſpreads itſelf all over the Town.

They do not let the Grapes lie ſtill in the Vat; they ſtir them and diſturb them: The Labourers trample them briſkly three different times, for the Space of two Hours each time. And to give a clear Idea of the Manner of treating the Grapes in the Vat; aſſoon as they begin to ferment in the Vat, they tread them for two Hours at the leaſt; ſix Hours after they tread them again for as long time as before; and ſix Hours after that they tread them the third time; and after that they put them under the Preſs.

It muſt be obſerved, that the Grapes of *Volnet*, of *Pomard* and *Beaune*, being fermented in the Vat in the Field, cannot be let ſtand above twelve or eighteen Hours there; thoſe of *Pomard* a little leſs; thoſe of *Beaune* ſo long, or a little longer, according to the Delicateneſs of the Ground, and the Heat of the Grapes: For there are Vineyards behind the Hills of *Beaune*, the Grapes of which don't begin to ferment till after they have been eight or ten Days in the Vat. *Note further*, That to give a Colour to the Wine, this depends on the Time more or leſs that it is left in the Vat. As for Example, The Wines of *Volnet* have the Colour of a Patridge's Eye. This is the Cauſe they do not leave the Grapes of this Ground but a very little time in the Vat; and if they ſhould let them be there but a little longer than they ought, the Wine would loſe its Delicacy, and would taſte of the Grape-ſtone or the Stalks.

After the Grapes have been, according to their Quality, more or leſs time in the Vat, and have been trodden, there ſwims over a Liquor that they call *Surmôu*. They have Caſks of ſix-ſcore Pots, or half Hogſheads of ſixty Pots ranged upon Chantiers, or Stillings for Hogſheads, into which, by equal Portions, they caſt in this firſt Running; and afterwards they put the Grapes that remain on the Preſs, when the *Surmôu* has been drawn off: And when theſe have been well preſs'd, all the Liquor that comes from them is equally diſtributed into thoſe Pieces where they have already put the unpreſs'd Wine: And then they open the Preſs, and afterwards with a Planer they cut the preſſed Marc three or four Fingers thickneſs round about, and put the Parings in the Middle, and afterwards preſs it again; then they cut it again, and preſs it the third time; and all the Liquors of theſe different Preſſings are equally diſtributed into the Tuns till they are full.

Upon which it ought to be obſerved, that the unpreſs'd Wine is the moſt light, delicate, and leaſt colour'd Liquor; that which comes of the firſt Cut of the Preſs the moſt racy, and that which comes from the ſecond and third Cut of the Preſs is more hard, red, and green; ſo that theſe three Sorts of Qualities, being united, make a Wine much better, more durable, and better coloured.

All theſe Pieces or Tuns being full, they leave the Bung open, and the Wine in a Fury, ſhakes and agitates itſelf in ſuch a manner, that it ſends all over the Cellar Fumes that will intoxicate, and which are in ſuch Motion, that a lighted Candle being carried thither will be extinguiſhed: And if this Wine be put in an Eſſay, and be ſhaken a little with the Hand, and you ſtop the Neck with your Thumb, the Eſſay will break in a thouſand Pieces.

In *Burgundy*, that which they call an Eſſay, is a little round Bottle, in Length about three or four Inches, and about two in Circumference, which grows leſs all of a ſudden at the Top, in order to form a little Neck open, having a little Rim to receive the Wine and the Cork.

The Wine having caſt its Fire and Scum out of the Casks, eight Days after they fill them up again, and ſtop them up with a *Vine* Leaf, which they ſpread over the Bung: And leſt the Vapours of the Wine ſhould move this Leaf out of its Place, they lay a little Stone upon it to keep it down; becauſe if they ſhould put upon it a Seal or a Bung, the Wine not having Air, would puſh the Head of the Casks out: Five or ſix Days after they ſeal it, and near the Bung they bore a Hole, and ſtop the Hole which the Gimlet has made in the Tun with a little Bit of round pointed Wood, which they call a Faucet, which they take out from time to time to let the Spirits evaporate; which Precaution prevents the Wine from burſting the Veſſel.

This is the Time when at *Beaune* are to be ſeen the Merchants from all the Corners of *Europe* who come to ſecure the beſt Vats for their Kings, Princes and Maſters.

The Commiſſioners and their Wine Conners prove the Wines although they are not yet drinkable. The Commiſſioners are the publick Managers, to which all thoſe who would have the Wines of *Burgundy*, addreſs themſelves either by Letters or in Perſon. Theſe are the Judges, which from time out of Mind, from Father to Son, have certain Experience of all the Vats; who know the Climates, Cloſes and the Cantons from which they are produced, and all the good Cellars; to whom it is ſufficient to write what Quantity of Wine one would have, and of what Diſtrict or Canton one would have it of, and provided they have the Purchaſe-money paid in the Space of the current Year, one may be ſure to be well ſerv'd.

Theſe Managers having received all the Commiſſions from private Perſons, go to the Citizens, and fill their Eſſays of the different Vats which they find in good Cellars; and with the Tickets that they tie to the Neck of every little Bottle, or the Name of the Vat, with the Quantity of the Pieces of Wine which they contain, they carry them to their Houſes, and let them be unſtopp'd; they examine and attend them carefully, and by the different Changes, Taſte and Colour, they ſee the future Colours and Qualities of the Wines that are in the Tuns from which the Eſſays are taken. They alſo make yet another Proof with the Wine which is in the Eſſays: They take Glaſſes, upon which they put a ſinking Paper, which they ſpread, and which juts out over the Glaſſes, and preſs their Finger to make a Concavity; which may contain a fourth Part of a Glaſs of Wine: The Liquor paſſes by little and little and filtres through the Paper, and ſtrains Drop by Drop in an impreceptible manner into the Glaſs which receives it. By the Sight of the Wine which paſſes through this Paper, they make good Conjectures founded upon a long Experience, concerning the deſtinated Taſte, of the Colour, and the Laſtingneſs of the Colour of the Wines they have proved.

The Commiſſioners having made their Purchaſes according to the Orders which they have received from their Correſpondents and Merchants, they make Preparations to ſend them according to their Orders: And as to the Price of the Purchaſe, they cannot deceive any Perſon without running great Riſques: For if they ſhould make thoſe which ſend for theſe Wines pay more for them than they can buy them for in the Cellar, they would expoſe themſelves to Hanging by Arret of the Parliament of *Burgundy*, who have made a Law for the aſſuring the Fidelity of Commerce of thoſe Wines; which Orders, that the Commiſſioners ſhould take one *Sol per Livre* for as much as comes to ſixty *Livres*; and and for what exceeds this Sum, they ſhall not take more than ſix *Deniers per Livre*. Thus a private Perſon who ſhall receive for ſix hundred *Livres* of Wine *French* Money, ſhall pay three *Livres* to the Commiſſioner, for what he ſhall have ſent above ſixty *Livres*; and for the five hundred and forty which are over and above, for which he is to pay the Commiſſioner, he ſhall not demand more than ſix *Deniers per Livre*, which will be the Sum of twelve *Livres* ſix *Sous*; which being added to the three *Livres* above, make the Sum of fifteen *Livres* ten *Sous*; a Sum which would amount to twelve or thirteen Shillings, according to the Exchange: And for this ſmall Profit, the Commiſſioner is oblig'd to advance his Money to the Citizens of whom he buys the Wines; and that too, when he does not receive his Payment from the Perſons to whom they are ſent, as it ſometimes happens: And the Commiſſioner that ſhall be convicted of taking more, whether by Books or other Proofs, will be puniſhed, as has been ſaid above.

The Commiſſioners having purchaſed and proved their Wines, according to the Orders they have received, they cauſe the Tuns to be new hooped, and put Bars ſurrounded with Pins of Wood of the *Aſpen* Tree, and mark them with the Town Mark: And it ought to be obſerv'd, that no other Country has a Right to imitate or counterfeit their ſecond hooping; and for the greater Surety, they put upon every Cask the Fire-mark, which is a B on the Top, two Inches in Length, with the Cypher of the Year in which the Casks were ſent from *Beaune* to go to any other Place.

Theſe are the Precautions that are taken at *Beaune*, by which the Wines that come from thence cannot be miſtaken: A Caution otherwiſe not very neceſſary, ſince they manifeſt themſelves ſo plainly by their Delicacy and their Superiority above all other Wines in the Univerſe: They are beſides very beneficial and proper to eſtabliſh and to preſerve Health; in this ſurpaſſing the Wines of *Champaign*, which flatten the Taſte, and grate the Palate; but which weaken and extenuate, enervate, and render dull, as one may ſay, the moſt healthful Bodies; and which alſo according to ſad Experience, and the Writings of the Learned, which I have read, breed the Gravel, the Gout, and the Stone.

After having given an Account of the Situation of the Town of *Beaune*, and the Hills which produce the Wines of *Burgundy*; after having related the Manner of cultivating their Vineyards, and of making their Wine; of proving it; of chuſing it; of buying it, I ſhall, next, explain the different Qualities of the Wines which theſe divers Hills produce: And in order to this, I ſhall divide what follows into three ſmall Articles. I ſhall treat firſt, of the forward Wines; ſecondly, of the Wines *de Garde*, or for keeping; and therein I ſhall treat of White Wines, and ſhall conclude in giving Inſtructions for the different Methods that are to be us'd in bringing the Wines of *Burgundy* to *London*, and will adviſe how the *Beaune* Wine may be ſent to *London* in Bottles.

The firſt Article of the Wines of Primeur *or the Forward Wines.*

We call that the Wine of *Primeur*, which will not keep good more than one Year, or that can be kept but a few Months in the ſecond Year.

The firſt Wine of *Primeur* grows at *Volnet*, which is a Village ſituated about three Miles from *Beaune*, upon a Deſcent of a Mile in Height at leaſt, and two Miles in Length on the Side which is expoſed to the Riſing Sun: This Village, as well as *Pomard*, have their Dependance on the City of *Beaune:* Since the Citizens have been their Lords, as I have ſaid before, theſe two Plots of Vineyards, have been oblig'd to receive the Law of their Vintages from the Magiſtrates and Sages named for this Purpoſe.

This Hill produces the fineſt, moſt lively, and moſt delicate Wine of *Burgundy*. The Bunches of Grapes of the Vineyards of *Volnet* are very ſmall as well as the Berries; the Branches riſe ſcarce above three Feet high through the whole Year; the Grapes of it are ſo delicate, that they won't bear the Vat more than twelve, ſixteen, or eighteen Hours; for if they be ſuffer'd to ſtand longer, they would take the Taſte of the Stalk.

This Wine is in Colour a little deeper than the Eye of a Partridge, it is full of Fire, ſtrong, light, it is almoſt all Spirit; it is, in ſhort, the moſt excellent of all *Burgundy*, which by reaſon of its Violence is not traded in; but its intoxicating Quality is ſoon diſſipated. The Duration of this Wine is from one Vintage to another, tho' it periſhes at the Beginning of the Dog-days; after which it changes its Colour, and is turned, but yet I doubt not but that it would keep longer in very cold Vaults. The fineſt of their Vats is drawn from a Canton of Vineyards, that is call'd *Champan*.

Pomard is the ſecond Plot of Vineyards of the *Primeur*: It is ſituate between *Volnet* and *Beaune*, not quite ſo high as the firſt, and a little higher than *Beaune*. It produces a Wine that has a little more Body than the preceding, and it is of the Colour of Fire, and has a great deal of Perfume and Balſam: It will hold good ſome Months longer than that of *Volnet:* It is more merchantable, and better for Health: If it be kept above a Year, it fattens, ropes, it waſtes, and becomes of the Colour of the Skin of an Onion. The beſt Vat is that of *Commaraine*, that will ſometimes keep eighteen Months, but that is according as the Year is.

The City of *Beaune* contains one very conſiderable Plot of Vineyards; it contains only four Hills, which are about four Miles in Length from *Pomard* to *Savigny*. The firſt of theſe Hills is called *St. Deſire*, the ſecond the *Montée Rouge*, the third *Les Greves*, and the fourth the *Fountain of Marconney*. Theſe different Soils produce Wines which participate of thoſe of *Volnet* and *Pomard*, without the Faults of them; they have a little more Colour, many good Qualities, and Laſtingneſs.

The Wines of *Beaune* laſt ſome more, and ſome leſs, but they don't laſt above two Years; they are ſweeter, more agreeable, and more merchantable than the two preceding, and much better for Health. The Colour of theſe Wines is not equal, becauſe that depends much upon the Manner of making them; or that they let it remain more or leſs Hours in the Vat, according as the Climate is more or leſs delicate where it is made. There are in theſe four Hills certain incloſed Cantons, which are in great Reputation. The *Feves*, the *Cras*, the *Greves*, as alſo the *King's Incloſures*, are very delicious.

Aloſſe is the fourth Vineyard of the *Primeur*: It is ſituated upon the Declivity of a Hill about three Miles from *Beaune*. This Valley is an Aſcent ſo gentle, that one can ſcarce perceive that one aſcends till one has come to the Top of it. This little Village produces Wines of an extreme Delicacy: They are leſs briſk than the former, but of a Taſte more flattering: The Colour is a little more ſoft, and leſs ſparkling, but fine; and, like the Hill that produces it, the Wine is too little elevated, and too much declining: It partakes neither of the Firmneſs nor of the Stiffneſs of the Wines of the Height of the Hills: It has all the Tenderneſs, nothing of the Hardneſs, and of conſequence is ſubject, in a little while, to grow ropy, and to take the bad Quality of Sweetneſs; nevertheleſs it is ſent to foreign Countries, but it requires much Choice and Judgment.

Pernand, which is between the laſt Vineyard and the grand Vineyard of *Savigny*, is of a greater Extent, but is of ſmall Account, the Wines being not very delicate: They are of the Quality of the precedent Vineyards, but harder and firmer, becauſe they are produced upon a Hill that is higher and ſteeper. There are ſome Vats very delicious, and theſe go into other Countries, but under the Name of *Beaune* Wine.

Chaſſagne is not very conſiderable for its Extent, but is of greater Reputation for its Wines. This, in my Opinion, would be more fit for *England*, becauſe it would better bear Carriage by Land and Sea. It is extremely ſtrong, full of Fire, and heady. It is commonly tart, which renders it more durable than the others: But if Perſons have Skill and Leiſure to bottle it in the proper Time, and to drink it when its Tartneſs begins to fall, it is one of the nobleſt Wines in the World. If I had the Office of providing the King's Wine, I would go into *Burgundy* to chuſe it; and in chuſing the Wine of this Climate I ſhould be likely to ſucceed. This is the only Wine one may leave in Bottles without Fear of its growing ropy, or changing its Colour, or growing eager, or turning. The longer you keep it, the better it is.

It is more balmy and nouriſhing, but nevertheleſs you may not preſcribe above three Years for the Bounds of its Duration. It will be fit for drinking at the End of the ſecond Year; ſometimes it laſts four Years, when the Vintage has been very good.

This is in the Rank of Wines in the *Primeur*, though its Duration is a great deal longer.

Savigny is a great Extent of Ground between *Beaune* and *Pernand*, ſituated in a Valley formed by the Separation of the two Mountains. As the Hills that compoſe this Vineyard are open to the riſing Sun by a great Space; and as they are ſhut up as they approach to the ſetting Side, they participate of the Rays of the Sun on one Side obliquely, and on the other directly. This Soil produces excellent ſtrong, racy Wines, which have both Body and Delicacy, when they have been drawn out into Bottles; but they muſt be viſited now and then, ſo as not to let ſlip the Time when they ſhould be drank. This would be a very good Wine for *England*; it will keep as well, and better than *Chaſſagne*: It is not ſo delicate nor ſo briſk, but it is more oily, and very good for Health.

Auxey is pretty near of the ſame Situation, in a Corner between two Hills, which open themſelves to *Mulſault*, or as far as *St. Romain*, where may be ſeen high Mountains crowned with very high Rocks. This Vineyard produces Wines more red and ſtronger than thoſe of *Savigny*, but they have not the Reputation of them. Theſe Wines have more Body than the preceding, and ought to be the Drink of all thoſe Gentlemen that would not ſhorten their Days by drinking thoſe heady ſparkling Wines, an Exceſs of which is ſo dangerous.

The ſecond Article, of the Wines de Garde, *or thoſe which will keep a great while.*

Nuis is a very ſmall Village, about nine Miles from *Beaune*, in the Road to *Dijon*. The Territory of this Village contains between four and five Miles in Extent. All thoſe Gentlemen that love the moſt delicate and healthful Drinks, have the Wines of the Hills of *Nuis* for their Tables: Theſe Wines are at firſt very rough, ſharp and tart: They require to be kept till their ſecond, third, fourth and fifth Year; and when their Roughneſs and their Hardineſs is gone, their Tartneſs being fallen, there comes in their Place a Perfume and Balmineſs very delicious. They are of a deep Velvet Colour, and yet neat and brilliant. *Lewis* the XIVth drank no other Wine.

The Cloſe of *Vougeot* is ſituated a League from *Nuis* on the Side of *Dijon*; it appertains entirely to the Monks of the famous Abbey of *Citteaux*, built between the *Saône* and this Hill. The Wine which it produces, comes nearer to that of *Chaſſagne* than to any other. It is very excellent, and is drank in foreign Countries.

Chambertin produces, to my liking, the moſt valuable Wine of all *Burgundy*. It is ſituated between *Dijon* and *Nuis*. It contains the Qualities of all the other Wines, without their Faults. This is what one may forget without Fear. I have drank it ſix Years after it has been produced, and it poured troubled and thick into the Glaſs, but grew clear immediately, and by its Motion recovered its Spirits, and a Colour the moſt lively and neat: And they alſo ſell it as dear again as the other Wines of *Burgundy*. It was ſold the laſt Vintage but one for forty, and fortytwo Pounds, *Sterling*, the *Chantier*, when the Wines of *Volnet*, *Pomard*, and *Beaune* ſold for not above twenty Pounds, *Sterling*, a *Queüe*, which contains, as I have ſaid before, four hundred and eighty *Paris* Pints.

The third Article, of White Wines.

Before I begin to treat on White-wine, it is proper to let you know that it is made from a maſculine Kind of Grape. This has two Qualities that the Grapes of the other Colour have not. The firſt is this: That if the Vintage be late, and that the white Froſts and great Cold come, it reſiſts the Hoar-froſts, while the black Grapes grow ſour, wither'd and ſhrivelled immediately.

The ſecond is, that as ſoon as theſe white Grapes are cut, they muſt be put into the Preſs without entering the Vat, and without being trod as the black Grapes are; for if they were put there, they would give only a livid, ruddy, yellowiſh Liquor. I thought myſelf obliged to acquaint the Publick with that.

Muſſault is, after *Beaune* and *Nuis*, the largeſt Vineyard of *Burgundy* in Extent; its Wines are generally approved in *Germany* and the *Low Countries*, and throughout all *France*; I know not whether they are ſo in *England*, or not. The Wines which this Soil produces, in all hot and dry Years, are delicious, ſparkling, agreeable, warm, and beneficial; they are not dear, and if they were well choſen, they would be an Honour to *England*, and a Pleaſure to thoſe that drank them. When they are kept above a Year and half, they ſometimes grow yellow and eager.

Puligny is a Vineyard next to *Muſſault*, but much more in the Plains, which produces the beſt White-wines; they are, within a very little, of the ſame Quality with the Wines of *Muſſault*, but their Fame is not divulged, and the Name is almoſt unknown.

Aloſſe, of which I have ſpoken in the Article of the firſt Wines, produces alſo excellent Wines.

Morachet is a little Plot of Ground between *Chaſſagne* and *Puligny*, in the Plain, which is in the Poſſeſſion of one Vein of Earth, which renders its Soil wholly of the ſame Kind; it produces a White-wine the moſt curious and moſt delicious in *France*; there is no Wine of *Cote-Rotie*, *Muſcat*, nor *Frontignan* that equals it. It produces but a very ſmall Quantity, and it ſells very dear; and in order to have a ſmall Quantity of it, it ought to be beſpoke a Year before; becauſe this Wine is always beſpoke before it is made. But great Caution is to be taken not to be deceived, for the neighbouring Vineyards of this Cloſe partake a little of the Quality, and oftentimes paſs for *Morachet*, and therefore it will be abſolutely neceſſary to have a faithful Correſpondent. This Wine has thoſe Qualities that neither the *Latin* nor the *French* Tongue can expreſs: I have drank of it ſix or ſeven Years old, and am not able to expreſs its Delicacy and Excellence.

I am now going to treat concerning all the Vineyards of the *Upper Burgundy*; thoſe who have paſſed the grand Road that leads from *Dijon* to *Lyons*, the Length of the Hills, will do Juſtice to my Exactneſs; and I deſire thoſe that have not been there, to believe that this Relation is agreeable to Truth.

I have an hundred times heard Boaſting of the Wines of many Hills near *Auxerre*, to which they give the Name of the Wine of *Burgundy*: It is true, thoſe Hills are in *Burgundy*, but they are ninety Miles diſtant from the true Hills, of which I ſpoke juſt now, which only produce theſe Wines of *Burgundy* which are in Reputation, and which they drink after two Manners, by the Noſe and by the Mouth, either both at once, or ſeparately; both at once, in that when one drinks them, the Pleaſure which he has in the Smell vies with the Reliſh it has on the Palate; and ſeparately, ſo that a Perſon that has been uſed to drink it, may know whether it be the true *Burgundy* or not by the Smell or ſweet Odour. The good Taſters taſte it by their Noſe, before they put it to their Mouths; and all the other Climates of *Burgundy*, as thoſe of *Chablis* and *Auxerre*, have no ſuch Quality as the true Wines of *Burgundy* have, altho' they are really made and produced there.

It remains for me to relate how theſe Wines may be brought to *England*. It has always been the Cuſtom to bring thoſe Wines from *Burgundy* in their Caſks; but as the Carriage is long, and there is oftentimes a Riſque run, ſo the Carriers, as well by Land as by Sea, are not always faithful; for notwithſtanding all the Precaution that can be taken to hinder them from drinking the Wine, they will always find out Stratagems to do it. If it be packed up in Caſks, with Straw and Linen Cloths, this is but a feeble Obſtacle to their Induſtry. And for all this Precaution, if the Caſk happens to leak by the way, this will be at the Peril and Loſs of the Purchaſer. If theſe Wines be put into double Caſks, this Precaution will have no better Succeſs than the foregoing, and is expoſed to the ſame Riſque; and the Caſks at the Vintages are a great Prejudice to theſe delicate Wines, becauſe this gives the full Scope to the Spirits to evaporate; and of conſequence they will cauſe a great Diminution of the Quality of the Wine.

It ought to be brought in Bottles from *Beaune* to *London*: For this Purpoſe ſome Agent, who buys the Wines by Order of the Perſon, ſhould be addreſſed to, to draw it out into Bottles, and to ſend it in Caſes into *England*. Theſe Caſes being filled, need but be carried by Land above ninety Miles to *Auxerre*, where they may be embarked on the River *Yone*, which paſſes into the River *Seine*, and from thence to *Paris*, and afterwards to *Roüen*, where are Veſſels which paſs very often to *London*.

If one would have them come from *Beaune* to *Calais* by Land, that will alſo be eaſy; for there are Carriers that go thither very frequently, who would go very willingly, provided they could have Caſes enough to load their Waggons.

The Agents of *Beaune* would alſo be very well pleaſed to bottle the Wine that they were ordered to buy, provided their Correſpondents would give Orders for enough to make a Carriage: As for Example, if two or three Perſons would join to give Orders for a thouſand Bottles, this would be a compleat Carriage: And as thoſe of *Volnet* draw their Wine into Bottles at the End of *December*, a Perſon that would have five hundred Bottles of *Chaſſagne* or *Nuis*, ought to join with another that would have the like Quantity. The Agent might bottle up theſe Wines a Year after the Vintage, either more or leſs; and the Purchaſers might receive the Wines of *Burgundy* exquiſite and delicious; and in like Manner all other Wines that they have a Mind to have. As to the Price of the Wines of *Beaune*, *Volnet*, *Pomard*, *Chaſſagny* and *Nuis*, it is pretty near equal, or at moſt the Difference is not very great. A *Queüe* of *Volnet* Wine contains four hundred eighty *Paris* Pints, which will make five hundred Bottles, and will coſt in the Country, ſome Years, ten, twelve, fourteen, or eighteen, and at moſt twenty Livres *Sterling*. The Carriage may coſt to *Calais* twelve or thirteen Livres; and afterwards from *Calais* to *London* a very ſmall Matter: So that taking the Years one with another, the deareſt Wine of *Burgundy*, except that of *Chambertin*, which is the deareſt, would ſcarce, in *London*, ſtand in fourteen or fifteen Sols a Bottle, the Entry not being reckon'd in.

The Method of making Wine in Provence.

The Delicateneſs of the Taſte of Grapes is not always a certain Proof of their Goodneſs for making Wine: It is not always with theſe Grapes ſo agreeable to the Taſte that the beſt Wines are made: We ſhould not be ſurprized that our Wines are not the moſt exquiſite, ſince we do not obſerve any Rule in the Choice of the Grapes, which ought to be done.

It is certain, that the Juice of Grapes of different Kind, cannot but produce a confuſed Mixture, which ſuffers divers Alterations in the Caſks, by the different Fermentation, which the ſulphureous Particles of the Grapes excite there, by which they ſuffer themſelves to be very eaſily opened at the Approach of the Heat. This is what happens to Wines which have been made of a Mixture of many Kinds of wild Grapes. Experience informs us, that Wine drawn from ſuch Grapes is very ſubject to ferment and grow foul, as ſoon as the Heats of the *Spring* begin to approach, which does not happen in the *Winter*, when the Coldneſs of the Air holds it, as it were, bound and embaraſſed by the ſulphureous Particles of the Wine. It is the ſame Thing in the Juice of the Grapes called *Claretos*, *Plan Eſtrans*, *Pignoulets*, &c. when they are mingled in too great a Quantity with the others. The common Fault of our Wine is, that they cannot be kept the Year throughout; they are apt to grow foul, or turn, as it is called, upon the leaſt tranſport.

The greateſt Part of our Citizens believe it to be the Fault of the Soil, principally the Vineyards planted in the Places where Plaiſter or tranſparent Stone is made, under which is contained all that Extent of Ground, which begins from *R. P. Capucins*, as far as *Aguilles*, which they commonly call *Payblanc*, i. e. *White Country*. But how many Vineyards have we planted in different Soils, that are ſubject to the ſame Vice? It is generally agreed, that the Soil which they call [*Gres*] Grey, is the beſt for Vineyards: Nevertheleſs, it is found, that the Quarter of *Molieres*, of *Repentance de Barret*, of *Montaiguez*, are not exempt from this Vice. I am of the Opinion, that it proceeds from the Mixture of too great a Quantity of different Sorts of Grapes. I cannot deny, after Experience, but the Nature of the Soil, the Culture, and the Dung they uſe, contribute very much to this Vice, which is what I ſhall hereafter examine into.

Therefore it is neceſſary to know what Grapes are fit to make good Wine, that may be in a Condition to be kept without being foul, or turning, and how to make it.

It is very true, that a Perſon cannot make from one Vineyard a great Quantity of Wine, that ſhall be at the ſame Time good in Quality. A Vineyard ought to be planted on thoſe high Grounds or Hills which are expoſed either to the South or the South-weſt.

And the Soil ought to be a Sort of brown, or approaching to it. Thoſe which we call *Arpielo*, *Malauſene*, *Saveon*, are Soils which are ſcarce proper to nouriſh Stocks that will produce Grapes for making good Wine. The Vineyards which are round about the *Peres Auguſtines Reformez*, commonly called *Saint Pierre*, are planted in a Soil of *Saveon* aforeſaid, very unfit for producing Grapes of a delicate Reliſh, or for making good Wine.

The Entrance into the Territory of *Tholonet*, is, for the moſt Part, a Soil which our Country People call *Malauſene*; and alſo the Wines that they produce are none of the beſt.

Thoſe Grapes ought to be choſen which grow upon Stocks that are planted in a Soil ſomewhat rocky.

After the Culture, it is very certain that good Wine cannot be drawn from Grapes that have too much Nouriſhment, and of which the Sap has not attained the laſt Degree of Concoction or Ripeneſs.

Thoſe which we call *Ollieros*, which are commonly dunged, and which they cultivate with Pains, do give a great Quantity of Grapes, but their great Nouriſhment is an Obſtacle to their making good Wine. Thoſe which we call *Open Vineyards* are to be preferred to them.

We ought alſo to prefer the Grapes of old Vineyards to thoſe of young ones. The proper Vineyards for making good Wine, are thoſe which have been planted twentyfive or thirty Years; the older they are, the more proper they are for making good Wine; and till the Vineyard has been made ſeven or eight Years, good Wine ought not to be expected from it.

As to the Choice of Grapes, we ought to mix ſome of the beſt Sorts that we have. Theſe Kinds are, of the White Grapes, the *Aragnan*, the *Reudeillat*, the *Peſeau Blanc*, the

Eſtrany, the *Uni*, the *Aubré*. Of the Black, the *Catalan*, the *Bouteillan*, the *Uni Negré*. The Muſt that is drawn from theſe Grapes ought to ferment in the Vat at leaſt three Weeks; when the Huſks muſt be ſeparated from the Muſt. It is a common Error in this Village, not to let the Wine ferment long enough.

It ought to be noted, that the Proportion which ſhould be kept between the Quantity of theſe Kinds is different, according to the Deſign of which every one has of keeping theſe Wines.

The Black Grapes, and above all the *Catelan* and the *Bouteillan* ſhould make more than half the Quantity of all the reſt.

Thoſe that deſire to have a Wine of a deeper Red, ſhould take a greater Quantity of black Grapes, and ought to let them ſtand a longer Time in the Vat, if they have Occaſion to change the Wine from time to time.

They make white Wine of the Grapes they call *Aubier*, *Uni*, *Roudeillat*, *Aragnan*, *Pignolet*. If they would have Wine proper to keep in the Heat of the *Summer*, they ought to uſe none but *Uni*, *Aubier*, and *Aragnan*.

No body is ignorant that we have Wines that are made but of one Species of Grapes; as that of *Muſcat* Wine, and *Claret*: For the firſt, they make Uſe of *Muſcats*, as well white as red; for the ſecond, of the Grapes they call *Clareto*.

They keep theſe Grapes with us during the whole *Winter*, and ſome part of the *Spring*, hanging upon a Beam in a Room. All ſorts of Grapes are not fit for keeping; thoſe Kinds that are call'd *Pendoulans*, or *Rin de Panſe*, *le Land de Poüere*, *le Verdau*, are the beſt for this Purpoſe; the *Aragnan*, and *Eſtrani*, are ſo likewiſe; alſo the *Clareto*, the *Muſcat* and the Red *Uni*: The *Barbarox* and the *Eſpaguin*, the *Taulier* and the *Roudeillat* will not keep ſo long. They ought to be gather'd full ripe, and before the Rains, and to chuſe none but thoſe that grow upon old Stocks.

They alſo preſerve thoſe Grapes to make what the *Latins* call *Uvæ Paſſæ*; not becauſe dry'd in the Sun, but becauſe they are expos'd to the Sun hanging: They call them in *French* dry'd Grapes: The *Provencials* call them *Panſes*. They make uſe of none but Grapes commonly call'd *Rin de Panſe* or *Pendulem*, or of *Rin Panſe Muſcat*, to make the beſt *Panſe*. They alſo make uſe of the Grapes which are call'd *Aragnans*, which is the moſt common *Panſe* in the hotteſt Places.

They alſo make uſe of the Grapes call'd *Roudeillats*, and the *Plan Eſtrani*. The Grape which we call the *Land de Poüere*, is not made uſe of with us for this Purpoſe; altho' I have been inform'd that they are uſed in hot Countries near the Sea-coaſts. They make their *Panſes* with us after the following Manner: They tie the Grapes in a String, and put them upon another String at both Ends; then they plunge them into a boiling Lye, in which they mingle a little Oil, until the Grapes ſhrivel, and afterwards expoſe them to the Sun for ſix or ſeven Days, and then they lay them in Rows in Caſes, or in what we call *Eſcortins* or *Couſins*, preſſing them gently.

No body is ignorant that the Juice of Grapes fermented in the Vat, and made into Wine, is a Liquor ſo precious and delicious, that it furniſhes us with a medicinal Aliment, and an alimental Phyſic; the Virtue of which is perceiv'd both in the Body and Spirit. It is not without Reaſon that it is call'd *Lac Senile*, i. e. *Old Mens Milk*, &c. and *Fomes Ingenii*, the *Tinder of Wit*; by *Homer*, &c.

Wine is different in Virtue and Delicacy of Taſte. The Difference proceeds for the moſt part from the different Nature of the Grapes with which it is made, the different Degree of their Maturity, and the Diverſity of the Soil where the Vineyards are planted; and alſo the different Culture of the Vineyards, and the Preparation of the Wine; to which may be added, the Difference of the Climates, according to the greater or leſſer Degree of Heat.

The *Romans*, as we learn from *Pliny*, were very curious in ſearching after the moſt excellent Wines; all their Differences conſiſted in the Places where they were made: As the *Setinum*, the *Cæcubum*, the *Falernum*, the *Gauranum*, the *Fanſtianum*, the *Albanum*, the *Surrentinum*, the *Maſſicum*, which were the moſt delicate Wines of *Italy* in the Time of *Pliny*. Among the Wines of *Greece*, they eſteem'd the *Maronean*, the *Thaſian*, the *Cretan*, the *Coan*, the *Chian*, the *Lesbian*, the *Icarian*, the *Sinyrean*, &c. Their luxurious Taſte carry'd them in Search of the Wines of *Aſia*, as that of Mount *Libanus*, and others, as may be ſeen in *Pliny*.

It is to be noted, that the *Romans* had their moſt excellent Wines from *Campania*, which is now call'd *Terre de Labour*, a Province of the Kingdom of *Naples*. Thoſe of the other Parts of *Italy* did not come near theſe laſt in Point of Excellency: The *Falernian*, the *Gauranian* and *Maſſic* were made from Vineyards planted on the Hills round about *Mondragon*, at the Foot of which paſſes the River *Garigliano*, antiently call'd the *Iris*. The *Cæcuban*, which differs nothing from the *Falernian* but in Age, (this is that which the *Latins* call the Length of Time which the Wines are able to preſerve their Strength) was produced in the *Terre de Labour*, as were the *Fundanum* and *Amyclum* near *Gaeta*, the *Sueſſanum* of *Sueſſa Pometia*, a Maritime Territory of the Kingdom of *Naples*; the *Calenum* about the Town of the *Terre de Labour*; and alſo many others, which that Province furniſhes the City of *Rome* with.

Theſe Wines, which are very excellent in their Nature, acquir'd rather by Age than by Art, a Degree of Perfection to which none of the other common Wines of *Italy* can attain to.

The laſt, which the *Greeks* call *Oligophora*, and the *Latins* *Tenuica* and *Paucifera*, are very eaſily preſerv'd by the Cold, or rather by a freſh Air, and grow eager by Heat. Alſo thoſe which the *Greeks* call *Polyphora*, or *Multifera* and *Vinoſa*, become more vigorous and ſpirituous by the Heat.

The Grapes of which the firſt are made, abound in crude Phlegm; the ſulphureous Parts of the Muſt are more dilated: The laſt, on the contrary, are drawn from Grapes that are more ripe; of which the Muſt or the ſulphureous Parts which compoſe it, are concentred and fix'd by the Evaporation of the humid Parts which dilate it. To this may be added, the abundance of the Sulphur of theſe laſt, which is the Cauſe of the true Strength of theſe Wines; and it is by being open'd that they acquire this Spirituouſneſs. It was only to procure this Opening, that the Antients invented the preparing theſe Wines in the manner I am going to expreſs.

Pliny informs us, That in the Year 633, from the Foundation of *Rome*, they lodg'd their Tuns full of Wine in Places cover'd, which were expos'd to the North, ſuch as we now call Cellars.

On the contrary, thoſe Caſks which were fill'd with vigorous and ſpirituous Wine, ſuch as *Polyphorum*, were ſet in an open Place, and expos'd to the Rain and the Sun, and all the Injuries of the Weather: Thoſe which contain'd Wines of leſs Strength, were kept under Covert: Thoſe which were full of a weak Wine, were put into a hollow Place, and cover'd with Earth.

Galen, in his Book *de Antidot. Chap.* III. and in the *Treatiſe of Vines*, that is aſcrib'd to him, remarks very much to the Purpoſe, That the Wines of the firſt Order, or *Polyphora*, were preſerv'd two or three Years in theſe cold Places; but if they let them lie there too long, they grew eager, if they did not remove them to warmer Places; as they us'd to practiſe in *Aſia* before the *Romans* had any Knowledge of it; and it was by this Means that the People of *Aſia*, as well as the *Romans* and *Greeks*, attain'd to the Art of making Wines keep ſo long.

The moſt antient *Epocha* of the Preparation of theſe Wines among the *Romans*, (as *Pliny* ſays) was about the Year of *Rome* 633. This Author, who liv'd a long time after in *Veſpaſian*'s Time, aſſures us, That theſe Wines had been kept for the Space of an hundred Years, and that they grew thick to the Conſiſtence of Honey; ſo that they could not be drank without mingling them with Water.

He alſo adds, *Quo generoſius eſt vinum, eo magis vetuſtate craſſeſcit*; *i. e.* By how much more generous the Wine is, by ſo much the more it grows thick by Age: The ſame that is ſeen in our Days in the *Spaniſh* Wines.

This Thickneſs of the Wines, of which I am ſpeaking, is leſs extraordinary than that of the Wines of *Aſia*, of which *Galen* ſpeaks in his Book of *Reſpiration*; which being inclos'd in large Flaſks, and ſuſpended near the Fire of their Chimnies, acquire, by the Evaporation of the Humidity, the Hardneſs of Salt. What *Ariſtotle* ſays of the Wines of *Arcadia*, expos'd to the Fire and the Smoak, is yet more ſurprizing: *Ita exſiccatur in utribus, ut deraſum bibatur*; *i. e.* So dry'd in the Bottles, that it is ſcrap'd off to be drank: It was ſo ſolid, that they were forc'd to ſcrape the Flaſks to drink it, and could not drink it without diluting it with Water.

The *Romans* prepar'd their Wines after the following Manner: They took the Muſt that had run from the Grapes that had been trod; they put them into a wooden Vat, of which the Staves had been bound together by Hoops or flexible Bands.

After the Wine had been fermented all the time neceſſary for ſeparating the groſſeſt Impurities, they drew it out of the Vat to put it into the Caſks; where it continu'd to ferment; and to aſſiſt the Depuration, they mingled as much Plaiſter, or Chalk, or Clay, or Powder of Marble, or of Pitch, or of Salt, or of Roſin, or of Lee of new Wine, or of Sea-water, or of Myrrh, or of Aromatick Herbs, as they judged neceſſary; every Country having its particular Mixture. And this is what the *Latins* call *Conditura Vinorum.*

They left the Wine in the Caſks until the *Spring* following; alſo many left them till the ſecond or third Year, according to the Nature of the Wine and the Country; afterwards they drew it out, to put it into Earthen Veſſels, which they did over on the Inſide with melted Pitch, and mark'd on the Outſide the Name of the Place from whence the Wine was made; and that of the *Roman* Conſuls, in whoſe Conſulate it was made. The *Latins* call'd this changing of the Wine from Caſks to Earthen Veſſels, *Diffuſio Vinorum*, or *Vina defundere.*

They had two different Sorts of Veſſels; the one the *Amphora*, and the other the *Cadus*. *Pancirollus* and others ſay, The *Amphora* was of a ſquare or cubic Figure; as to the Contents, Authors are not agreed, but moſt ſuppos'd they held about eighty Pounds of Liquor. This Veſſel was contracted at the Neck. After it was fill'd with Wine, they ſtopp'd the Mouth cloſe with Cork. The Cade was of the Figure of a Pine-Apple, which is ſuppos'd to contain half as much more as the *Amphora*. Theſe Veſſels being ſtopp'd, were carried into a Room expos'd to the South, ſituated in the higheſt Story of the Country-houſe where the Wine had been prepar'd. This Place was call'd *Apotheca.*

It was to diſſipate the ſuperfluous Humidity of the Wine, that they expos'd theſe Veſſels to the Heat of the Sun, and of that of the Fire, and of the Smoak, which has given to this Place the Name of *Fumarium*, becauſe of the Smoak which was gather'd by the Funnel, through which the Smoak of the Fire was carried off, when it was lighted below.

Theſe Wines could be kept for two hundred Years, and would, as has been ſaid, arrive at the Conſiſtence of Honey; during which, *Adhuc Vina ducentis fere annis jam in ſpeciem redacta mellis aſperi, etenim hæc natura vini in vetuſtate eſt*, ſays *Pliny*, Lib. xiv. cap. 4. So that it is troubleſome to drink this Wine becauſe of its Thickneſs; and in order to render it drinkable, they diluted it with warm Water, to give it a Fluidity, and afterwards they paſſed it through a Strainer; and this they call'd *Saccatio Vinorum*, as *Martial* ſays,

Turbida ſollicito tranſmittere Cæcuba ſacco.

It is true, they had other Wines of the ſame Nature, which they did not paſs through a Strainer; as the *Maſſicum*, which they only expos'd during a Night to the Air, to procure a Fluidity and Depuration; as *Horace* ſays, *Lib.* ii. *Sat.* 4.

Maſſica ſi cœlo ſupponas vina ſereno,
Nocturnâ, ſi quid craſſi eſt, tenuabitur aurâ,
Et decedet odor nervis inimicus: at illa
Integrum perdunt lino vitiata ſaporem.

This luke-warm Wine had been very diſagreeable to drink, if they had not cool'd it with Ice or Snow, whether in mingling it with the Wine, or ſetting the Bottles in Ice: The moſt Luxurious mingled the Snow with the Wine, and paſſed it thro' a ſilver Strainer, which *Paulus* the *Juriſconſult* calls *Colum Vinorum.*

Of the Method of Planting Vineyards in Orleans.

Of the Diſtance that may be given to the Ridges, and to the Paths when a Vineyard is planted. The different Kinds of Plants. Of planting between, and of plucking up old Vines, *and planting again.*

The Rows ought not to be open'd till after the Ground that is deſign'd to be planted has been mark'd out; to the end that a Length and Breadth proportionable and uniform may be given to all the Ridges and Paths, as much as the Ground to be planted will permit. And foraſmuch as the *Vine* receives its Nouriſhment in the Ridge, it will be proper to give it ſome Inches in Breadth more than to the Paths.

The moſt common Practice is to allow five Feet in Breadth for the Ridge and for the Path when red *Wines* are planted, eſpecially the *Auvernats*, whoſe Branches ought always to be train'd-in pretty long. This is the beſt Method for this Sort of *Vines*: And the Plants ought to be planted two Feet three Inches diſtant one from another. Some do not exactly obſerve this Diſtance, they allow but four Feet and an half for a Ridge, and for a Path.

There are alſo ſome that allow but a Foot and an half Diſtance between each Plant, when the Ridge and the Path have no more Breadth than that which I am about to mention; but the *Vines* of theſe Plants planted ſo cloſe together, ought, of Neceſſity, to be twiſted circularly; and as their Roots will, in a few Years, run one into another, the *Vines* will not laſt ſo long; beſides, they will require to be a little oftener and more plentifully dung'd than thoſe that have been planted at a greater Diſtance.

There are ſcarce any but *Vignerons* which allow ſo little Breadth to their Ridges and their Paths, and who plant their *Vines* ſo near one to the other, becauſe they are often renewing their *Vines*, from whence they have always young ones, which gives them Occaſion to have their Lands trenched; from whence they gain'd more Advantage than the Citizens, who might therefore do the ſame.

Others, on the contrary, allow near ſix Feet for the Breadth, and ſometimes more for the Ridge and the Path, but this certainly is greater than is poſſible to dig or cultivate between the Stocks; which is the beſt Manner of performing this Work. And when they dig otherwiſe, they will have a great deal of Trouble to work to the Middle of the Ridge, which nevertheleſs ought to be as well digg'd as the reſt.

But the *Vignerons* of *Burgundy* do not work ſo far; when the Ridges are ſo large, they content themſelves to touch but lightly the Middle of theſe Ridges, and they dig the Rows of Plants a little leſs. It is then advantageous for the Citizens not to give ſo much Breadth to the Ridges.

Thoſe *Vignerons* that purchaſe Vineyards which have the Ridges ſo wide, pluck them up oftentimes, that they may be able to plant others there, where they allow much leſs Breadth for the Ridges and the Diſtance between the Plants, without concerning themſelves about the *Vines* laſting the leſs while.

But the Citizens ought to follow a better Method, which is to give five Feet for the Breadth of the Ridge and the Path, and two Feet three Inches for the Diſtance between each Plant, eſpecially when one plants *Vines* of *Auvernat*; becauſe being furniſh'd with Layers, the Ridge muſt neceſſarily be larger, and the Plants at greater Diſtance the one from the other, that they may find more Nouriſhment, and that the Shoots of the *Vines* may be extended the better.

A Vineyard planted after this Manner will laſt longer, will defend itſelf better againſt the *Winter*'s Froſts, will produce finer and better Fruit, which will ripen better, and of conſequence make better Wine; and alſo the *Vignerons* of *Burgundy* would find their Account in planting of their *Vines* in this manner, in that they would have fewer *Vines* to tie, to prune, and to diſbranch, &c. becauſe there are a great many fewer Plants in thoſe whoſe Ridges or Paths are wide, and the Plants leſs crowded; and for this Reaſon there would be but few *Vignerons* but would be of this Opinion.

When I ſay, that when one plants *Auvernats*, they ſhould have five Feet in Breadth for the Ridge and the Path, and two Feet three Inches Diſtance between each Plant, I ſpeak of thoſe *Vines* planted in a very good Bottom of Earth, becauſe they will laſt many Ages, being renewed after the uſual Manner.

For as to thoſe Lands where one is obliged to renew the Vineyard in about twenty or five and twenty Years, it will be ſufficient to allow four Feet and a half for the Breadth of the Ridge and the Path, and twenty Inches for the Diſtance between each Plant; becauſe this *Vine* will not laſt a very long time, by reaſon the Roots will grow large and ſpread far in the Earth in ſuch a manner that they would injure one another. I ſuppoſe nevertheleſs this Land to be paſſably good for otherwiſe the Breadth of the Ridge and the Path muſt be greater, and the Diſtance between each Plant, or the Vineyard, muſt be the oftener dung'd.

The *Paillots* are almoſt all compos'd of two Ridges, which contain four Rows; to which they allow nine Feet in Breadth, to the end not only to hinder the too great Heat of the Sun from ſcorching the *Vines*, that are planted in a Land that is of a burning Quality, (for it is only in ſuch Lands that they make *Paillots*) but alſo in order to provide that the Plants may receive the more Nouriſhment, and that the Rain which falls may not ſo eaſily drain away, but may remain a long time upon thoſe Lands that can never have too much of it; and it is for this Reaſon, that one is oblig'd to plant there before *Winter*.

Theſe *Paillots* are planted as the other Vineyards, where they allow four Feet and an half for the Ridge and for the

Path, and as one *Paillot*, and its Path has ordinarily but nine Feet and a half of Breadth, ſo their Plants are diſtant the one from the other, pretty much the ſame as thoſe *Vines* planted after the Manner I am about to ſpeak; which may be eaſily underſtood by the Quantity of Plants which there are in the Vineyards, planted after theſe different Manners.

They faſhion theſe Plants of the *Paillots* as thoſe which are planted in Ridges; and the Year after they have been planted, they join two together, which form a *Paillot*. It is requiſite that the Land which one deſigns to plant with *Paillots*, be diſpoſed as that which is planted in Ridges.

There are three Sorts of Plants; thoſe from Cuttings, from Layers, and the old *Vines* that are pluck'd up to be replanted.

The two firſt Kinds are very well known by *Vignerons*, and the third but very little; but they are never the worſe for that, as I ſhall make appear in the following Articles.

The Cutting is a young Shoot of the Year that has no Roots: They always leave at Bottom a Knot of the Wood of the preceding Year. Theſe are the moſt commonly us'd. They give it no other Management, than to cut off the * Claſpers and the Tops at the ſame time that they take 'em off from the *Vines*, and lay them down in the Earth in a Bundle, when they cut them before *Winter*, and cannot plant them till the *Spring*.

This Plant is good, and commonly ſucceeds when it has been well choſen, being planted in Lands well diſpos'd, and well cultivated; but yet there is an Inconveniency in uſing it, and that when it is to be planted in Lands that are naturally moiſt, or that retain the Water: If it be planted early and there fall cold Rains in great abundance, the Plant ſoaks in the Water, and the Skin or Rind comes off, and it periſhes inſtead of taking Root: And if it be planted too late, and the great Heats and Droughts overtake it before it has put forth Buds that are paſſably ſtrong, it is ſcorched; wherefore it is better to make uſe of the ſecond Species of Plants, not only in theſe Sorts of Lands, but all others.

The Layers are the long Shoots of *Vines* of three Years Growth, which have ſmall Roots, and are better, and leſs liable to fail. Theſe may be planted at all times, and in any kinds of Land, provided they are ſuch as don't retain the Water. In this caſe, it were better to wait till *March* to plant them, or at leaſt till the Ground appears healthful, for we ſhould never plant in Ground which is very wet.

Before the Layers are planted they ought to be prun'd, that is, to cut off a few of their Roots; and when they are weak at the Place where they were bent, theſe muſt not only be cut, but alſo the other Branches or Spurs, leaving that which has the moſt and ſtrongeſt Roots.

The Layers are a great deal leſs ſubject to ſoak in the Water than the Cuttings; becauſe having Roots before they were planted, they make new ones ſooner than thoſe which have none.

It is true, theſe Layers are more rare than the other, but it is an eaſy matter to render them common enough, becauſe one may have whole Acres of them: And all the Precaution that is neceſſary for it, conſiſts in making Layers, when they are well grown, from the Shoots.

Theſe may be planted in two different Places, either in ſome Piece of Land deſigned ſolely for this Purpoſe, or in the Middle of each Ridge, at the Time that a Vineyard is planted.

If they be planted in a particular Piece of Ground, they muſt be laid in Rows betwixt the *Vines*, and there ſo, that betwixt each Row and the Shoot there may be a ſufficient Diſtance, that the Shoots may not hurt one another, and that the *Vigneron* may have Room to paſs between them when he is trimming them; for he muſt hough them three times a Year, to hinder the Weeds from growing about them and choaking them, and depriveing them of Part of their Nouriſhment. Theſe may be taken up at the End of two or three Years, according their Strength.

This Portion of Ground is a Sort of Nurſery, ſince the Gardeners make them, that they may have Plants to plant in thoſe Places where they are wanting.

I am alſo of the Opinion, that it is the Prudence of a Citizen to have on his Eſtate (eſpecially ſince the Cuttings do not take Root but with Difficulty) a Place where he may always have Layers in as large a Quantity as he pleaſes or ſhall ſuffice for all thoſe that ſhall not ſucceed, at leaſt if they be not well choſen, and which require a particular Care in their Cultivation.

I ſhall conſider, at the End of the following Article, after what manner we ſhould plant the Layers in the Ridges.

It is for the Intereſt of a Citizen to order his Affairs ſo that his Vineyard may be always full of Plants, to the End that it may produce a good Quantity of Wine, becauſe it often happens, notwithſtanding all the Precaution that can be taken to keep a Vineyard well furniſhed, that it will want to be ſupplyed, by reaſon of the Quantity of Plants that die from time to time; and becauſe one cannot always ſupply their Places by the Means of Layers; and becauſe ſometimes there will not be Wood enough upon the *Vines* that are near for that Purpoſe, and that it would not be proper to make uſe of the Top of the Shoot for ſeveral Reaſons that might be given; and therefore it will be proper to place Plants between the others.

Some *Vignerons* will ſay, that it is very rare that theſe middle Plants ſucceed in a Vineyard where they are planted. To which it may be anſwered, That it is true, that a middle Plant may not ſucceed, when the Earth has not been well prepared before the Planting, or when it has no other Management but of the Vineyard in common; but 'tis very certain that it will ſcarce fail, if Care be taken, after the Vintage, to pluck up the dead Shoots, to open the Earth to a good Depth before *Winter*, not only to the End that it may mellow, but alſo that the *Vines* may not be damaged in cutting off Part of its Roots, by which it would greatly be weaken'd, if it were not done before the *Spring*; and if in every Hole were put a Basket of freſh Earth, or about the twentieth Part of a good Scuttle-full of well-rotted Dung, eſpecially when the Plant is ſet in ſtony, clayey or gravelly Ground; for if it were too hot, it might burn the middle Plant, or breed Vermin, which would gnaw the Plant and kill it; alſo to tie the *Vine* after ſuch a manner that its Shoot may not hurt the middle Plant, and, in fine, to clear round oftener than the *Vine*, in caſe it has need; for it will be difficult for it to take Root, if the Weeds choak it: And this is the Reaſon, that among the Works relating to *Vines*, where, as often as the Weeds appear, it is convenient to hough amongſt all the Shoots that have been newly planted, it is always beſt to give this ſmall Stirring immediately after Rain.

I have ſeen among *Vines* very ſtrong in Wood, and of an hundred Years of Age, a middle Plant very ſtrong to the third Eye, and which always continued to do well; and I can affirm, that theſe *Vines* are planted in as ſtrong Lands as any are in our Plot of Vineyards. Now if the middle Plant does well there, as it is certain it does, we may take it for granted, that it will ſtill do better in thoſe Lands which are light: And hence it is, that there is not any Land where one may not plant it, or where it will not ſucceed.

Perhaps the *Vignerons* may ſay, that a middle Plant will be worth nothing among young Vines, becauſe theſe puſh with ſo much Force, that their Shoots would choak it.

I agree that it may ſometimes ſo happen; but then this is a Proof, that the Year following there will be found in this Vineyard Wood enough to make Layers there: In like manner, it would be uſeleſs to ſet a middle Plant, becauſe it is more likely to fail, and becauſe it will not produce Fruit ſo ſoon as the Layers, which produce it the ſame Year in which they are made.

This Reaſoning is more juſt than the Conſequence that they would draw from thence; that is to ſay, that it would be uſeleſs to plant a middle Plant: For if a *Vigneron* ſhould have the Malice every Year to cut off the Wood of the Vineyard, which might ſerve for the making the Layer, and not ſet a middle Plant there, the Vacancy that would be there, would never be fill'd; and this is the Reaſon that a middle Plant ſhould every Year be ſet in the empty Places, to the End that they may be filled out with the Layers. But this middle Plant doing well in the Vineyards of the *Vignerons*, I cannot ſee any good Reaſon that it would not ſucceed equally in thoſe of the Citizens, where the Plants are commonly planted at a greater Diſtance one from another than in the Vineyards of the *Vignerons*, where the middle Plant does very well.

The Plant of old Vineyards, or rather the old *Vines* alſo plucked up to be replanted, is yet another Species of Plant, which, without doubt, appears to the *Vignerons* a Novelty which ſurprizes them, becauſe it is not in their Practice, that is to ſay, in their Heads.

But the Method that I propoſe will not thence be the leſs good in itſelf, and will not fail to ſucceed; provided that the Earth, which is deſigned to be replanted with theſe old *Vines*, has been well prepar'd, and if what I ſhall direct be exactly obſerved.

---

* *Druges*; i. e. the young Suckers or dangling Shoots, which uſually puſh forth after they have rubb'd off the Buds of the *Vine* at the Height of the great Props. Theſe *Druges* begin to puſh ſometimes long before they are rubbed off, and often produce Grapes; theſe ſeldom ripen, becauſe they do not flower till towards the End of *July*. Theſe *Druges* do ordinarily proceed from thoſe *Vines* that puſh with a great deal of Force and Vigour.

It frequently happens that one has old Vineyards, of which the Plants are not equally good; and where there is ſo great a Quantity of Plants wanting, that inſtead of filling it by Layers, Shoots, or middle Plants, the void Space that is there will cauſe one to determine rather to pluck them up, becauſe the *Vignerons* have an ill Opinion of the Layers and Shoots, and they will ſay, that theſe Plants ſet between will not ſucceed.

The beſt Method that a Citizen can take on this Occaſion, is to pluck up a Vineyard when he finds it in this Condition. But as it is the Cuſtom to allow the *Vigneron* all the Wood for his Labour of plucking it up, becauſe they think the Wood is good for nothing but to burn, I would give them to underſtand, that they may make a great Advantage of it.

I ſuppoſe, in the firſt Place, that theſe old *Vines* are of a good Kind. In the ſecond Place, that, if there are any Shoots of a bad Kind, Care has been taken to cut them down to the Ground ſome time before the Vintage, or ſome Years before one pluck up theſe *Vines*, to the end that they may not be confounded with thoſe that are reſerv'd to be replanted.

In the third Place: If the Land where one would replant theſe old *Vines* has been well prepar'd; or in caſe one has a Mind to replant the ſame in the Ground from whence they have been pull'd up, and if it has been plentifully dung'd:

All things being prepared, there needs no more but to know after what manner theſe old Plants plucked up, are to be cut before they are replanted.

Before this Sort of Plant is put into the Ground, the Roots muſt be cut with a Hatchet, eſpecially the biggeſt, and only leave two Knots of this great Root below the Stock, and at the Top the largeſt and youngeſt Shoots, provided that they are ſound and healthful: Then in planting of them, the two Knots of the old Root muſt be buried, in caſe that it has large ones; if not, the large Stock only down to the Place where the Shoots are produced, ſo that the young Wood may be two or three Inches covered: And in caſe it be too far from the Stock, you muſt make the End of the Shoot that is on the Side of the Stock go as far as the Row, and lay it ſloping, in caſe it be too long.

It ought always to be ſo ordered, that what young Wood there is bury'd, which comes out of the Ground, be cut near to the Superficies only ſome Weeks before the *Vine* begins to puſh.

When this old *Vine* has been replanted, it ordinarily makes new Roots at the End of the old; and when it fails to puſh at this Place, as it ſometimes happens when it is too old, it infallibly makes new ones at the young Wood that has been buried; and this old Root and the Stock rot ſome Years after the *Vine* has been replanted.

In the firſt Year this Plant puts forth a Shoot above four Feet in Height, and alſo produces ſome Grapes which are pretty good, and ripen very well, when Care has been taken to cut off the Shoot at the proper Time.

The ſecond Year, it gives more Wood and more Fruit, provided that it be cut low. And in the third or fourth, at the lateſt, one may have a full Vintage from it. I have ſeen in one Place, in this Vineyard-Plot great Pieces of old *Vines* replanted after the aforeſaid manner, which have, at the third Bud, not only fine Fruit, and a ſufficient Quantity of it, but even, to the fourth ſo well condition'd, that one might take thence a Plant without hurting the Wood which ought to be kept to ſerve for the *Vine*.

Nevertheleſs, theſe Lands which I ſpeak of are not better than thoſe of this Vineyard-Plot, for they are in the Pariſh of *Boigni*, and are not accounted any better than theſe are; which makes me believe, that old Vines planted in good Lands would bear better there.

If there were any Reaſon to fear, leſt the young Wood buried would ſoak in the Water, &c. in caſe that it were planted before *Winter*, it may be deferr'd till *Spring*; and then they muſt not fail to prune the Plant at the ſame time that it is put into the Ground, or ſome Days after.

Nevertheleſs, I believe that one may plant this old Plant at any time, and in any ſort of Ground; becauſe thoſe that I have ſeen, which had been newly planted, have done very well in moiſt Lands.

But not to run too great a Hazard, the Experiment may be made after the Manner I propoſe, only upon ſome Ridges.

But ſome may ſay, To what Purpoſe ſhould we bury an old Stock, which has often two Knots of the old Root, and one Stem? Would it not be better to plant none but young Wood of theſe old *Vines*, or to leave only the young Wood on one Part of the Stem?

I anſwer, That this laſt Method is not to be abſolutely rejected, becauſe, perhaps, it may ſucceed. Nevertheleſs, that which I propoſe being the more certain, becauſe it is founded upon Experience, and the other yet has not, it ought the rather to be follow'd; for this old Root, this Stock or Stem, let it be as big as it will, is not ſo uſeleſs as may be imagined, becauſe it ſerves for a Reſerve to keep in the Sap, and thence furniſhes this young Wood, until it has made ſufficient Roots where it has been buried, whence the new Roots are produced indifferently; for I have ſeen of them produced both from this old Wood, and the new that has been buried.

I am of Opinion, that there is Reaſon to doubt, whether one Part of a Stem can produce the ſame Effect, becauſe it being ſlenderer, it contains much leſs of the Sap than a Stock joined to ſeveral Joints of old Wood, united in an entire Stem.

Of the Time and different Manners of planting a Vineyard.

Lands being of different Natures, there ought alſo to be different Times of Planting.

In Lands that are ſandy or full of Flints, as thoſe of *Olivet* and *St. Meſmin*, and others, the Bottom or Soil of which does not retain the Water, one may plant and interplant after the Leaves of the *Vines* are fallen, until the Beginning of the Severity of the *Winter*, without being under any Apprehenſion of the Plants not ſucceeding; becauſe theſe Sort of Lands never retaining the Water, are always wholſome at the Bottom, and therefore the Plants ſet in them will ſucceed.

They do not ordinarily plant in the Lands of *Olivet*, of *St. Meſmin*, &c. whole Pieces of *Vines* entire in the Places where they have been already, becauſe the Cuſtom is, not to pluck up in theſe Lands thoſe Plants that they find good, either as to Wood or Kind.

As for myſelf, I have always found that theſe different Stools mixed among very ſmall ones, make a Groteſque Figure in one and the ſame Piece of Land, and could never approve of this ridiculous Method.

I think it would be much better to lay down theſe Shoots of *Vines*, as Layers, or to pluck them up, and plant them again elſewhere; or to plant them in the ſame Place, cutting them after the Manner as is done to old *Vines*, which are replanted after they have been plucked up, as may be ſeen in the foregoing Article. But this laſt Method appears to me to be not ſo good as the firſt, which is, to make Cuttings of the Branches which remain upon the *Vines* that have been plucked up.

In ſtrong Lands, or ſuch as retain the Water, one ought not to plant but in the Month of *May*, or elſe the Beginning of *June*, becauſe it is not eaſy to make a *Vine* take Root in theſe Sorts of Lands, the Years being often very hot and dry, or very rainy, which are equally to be feared, in reſpect to the Plant ſet in them.

When the Rains are frequent and cold, the Plant imbibes the Water in the Earth; and when the Seaſon is too dry, its Bark burns towards the Surface of the Earth. It is eaſy to remedy, or rather prevent this ſecond Inconvenience, as will be made appear in the following Article. But as to the firſt one cannot do it; for it is very difficult to foreſee the Time when it ought to be done. A Plant ſo imbibing is abſolutely dead, paſt Recovery, and ſo there is no Remedy.

And as in an Eſtate of but a ſmall Extent, it often happens that the Lands are of different Natures, and that of Conſequence the Plants of one certain Species will not do well but in one Part of theſe Lands, and will ſucceed ill in another; and that the Seaſons are different from one another: And ſince they too often happen to be either too hot or too cold, or too rainy, and that the Kinds of the Plants are good or bad, according to their Nature, and that of the Ground on which planted, and the Diſpoſition of the Seaſon, I am of Opinion, to be more certain not to plant any Plants but what will ſucceed, and to have always ſome Vintage to gather, that it will be proper to plant ſeveral Kinds of Plants, according to the Lands they will agree beſt with, eſpecially if we be not very ſure that one Species of Plant will do better than all others: In ſuch Caſe, we ſhould plant none but that which may ſucceed there.

When I ſay, that it is often advantageous to have different Kinds of Plants in a certain Extent of Land, I do not mean that you ſhould put many Kinds of Plants in one and the ſame Ridge, or in one and the ſame Row, as is common for *Vignerons* to do, when they plant Vineyards for thoſe who are obliged to make but one Sort of Wine of all Sorts of Grapes, which nevertheleſs they would have paſſed for pure *Auvernat*, altho' there is not in it, perhaps, above a third Part; but I mean, that in every different Kind of Land, there ſhould be planted but one Kind of Plant, to the end that, every Kind being ſeparate, we may, in the Time of Vintage, eaſily make ſuch Wine as we deſire, which will be very difficult, if all the different Species of Plants be planted confuſedly one among another; fot there will ſcarce be found among the Vintage, Gatherers, either Men or Women, ſuch as have Skill enough to diſtinguiſh them; and beſides, if they had, it would be a Loſs of Time.

Thoſe Citizens who would have on their Eſtates nothing but *Auvernat*, ought to watch their *Vignerons* while they are planting; for they have the Trick of mixing the hard *Samoreau* and *Gois*, and other bad Kinds.

And when a Citizen would make good Wine, he ought to examine whether the Grapes be come to their full Ripeneſs, and he is obliged to leave the bad Grapes that are not ripe, which the *Vigneron*, ſome Time after, does not fail to take for his own Drink, to meliorate it, or to make Wine or Rape: But to remedy this Inconvenience, a Citizen ought to look over his Vineyards ſome Days before, to ſee whether his Grapes are equally ripe, and to take Notice which are leſs than the others, and which are not ſo good, and he ſhould cut thoſe *Vines* down to the Surface of the Ground; and the following Year he ſhould give Order to his *Vigneron* to ſupply their Places by the Means of Layers or Cuttings.

A Vineyard may be planted after two Manners, either upon the even Ground or in open Rows.

In planting upon the even Ground, when the Land has been levelled and marked out, they make a Hole with a Spade to put in the Plant; but it ought nevertheleſs to be ſuppoſed, that this Land has been prepared and well trenched.

The Manner of planting a Vineyard in open Rows, is almoſt the only one in Uſe in the *Orleannois*, and is, without Contradiction, the beſt; in that it is certain, that in planting in this Manner, the Earth has been opened and removed even to the Bottom, which by this Means will become better furniſhed, and the Roots of the *Vine* will be capable of ſpreading themſelves.

The beſt Time to plant Cuttings which have been bundled and buried in the Ground, is, when the Rind ſwells, which may be known by a Kind of Protuberance, which riſes round about the Wound, and alſo by the Buds being juſt ready to open; and that the Cuttings may not dry too much, they ought to be kept for ſome Time in a Veſſel full of Water, and not to be taken from thence, but as they are planted; for if the Heat ſhould ſhrivel thoſe that are planted, they will not ſo readily take Root, and many of them might die.

For this Reaſon it is better to plant a Vineyard in a rainy, moiſt Seaſon, or at leaſt cloudy, than when it is too hot, or there is a too drying Wind.

The beſt Manner to lay down the Shoot of a Plant, is to put the End that is to be placed into the Ground on the Side of the Ridge, to the end that it may be able to ſtrike out Roots from all the Buds or Eyes on both Sides, and and that it may have Nouriſhment from the whole Breadth of the Ridge, on which the Earth ought to have been removed.

Some *Vignerons* of the Citizens lay down the Shoots of the Plant, not according to the Breadth of the Ridge, as it ought to be, but the lengthwiſe of the Row, that is to ſay, all the Length of the Path; and I can't ſee the good Senſe of this Manner of Planting: I believe thoſe that do it, do it more out of Malice than Ignorance. Alſo the Wound of the Cutting of the Plant ſhould be laid down ſide-wiſe to the Bottom of the Trench. When the Plant is laid down, and they would cover it, the large Clods of dry Earth ſhould not be put immediately upon the Sets; for the Heat will eaſily penetrate through the Vacuities that it finds there, and dry the Plant, and hinder it from taking Root: For this Reaſon great Care ſhould be taken to put the fineſt Earth, that has been moſt ſtirred, and is moiſt, and to preſs it down well with the Foot, to the end that the Plant being preſſed on all Sides, and planted on a ſoft, moiſt Earth, it may ſtrike Root the more readily and ſurely, than if it takes the Air at any Place where the Earth does not touch all the Buds or Eyes where it forms Roots.

There muſt alſo be one good Bud at the Superficies of the Earth, becauſe this is that by which the *Vine* muſt put forth.

For in the greateſt Part of this Vineyard-plot, the Cuſtom is to plant a Vineyard no other Way but by Ridges; one Ridge is compoſed of two Rows, and when four of them are joined together, or only three of them, the Name of *Ridge* changes into that of *Paillot*, as may be ſeen at *Olivet* and *St. Meſmin*, and in the Places where the Vineyards are formed after this Manner.

There are alſo found ancient *Paillots* of eight Rows, which gives Reaſon to believe, that ſometimes they planted upon the flat Ground in theſe Sorts of Lands, that is to ſay, had neither Paths nor Ridges.

They commonly make uſe of two different Utenſils of Iron, to make the Hole where they put the Cutting of the Plant, either a Spade or a large Kind of Pick-axe. The firſt is the moſt proper to make good Work, provided the Earth be wrought the whole Length and Breadth of the Ridge, and alſo the Depth that the Plant is laid, that is to ſay, as far as the Hollow of the Earth.

When they make uſe of the ſecond Utenſil, it is commonly with a Deſign to make bad Work; for the lazy *Vignerons* content themſelves in making a Hole to put the Cutting of the Plant in, without digging the reſt of the Ground.

But by this laſt Way of Planting, it often happens, that the young Roots of the Plants, finding nothing but a hard Earth, into which they are not able to penetrate, it is impoſſible that they ſhould be able to extend themſelves as they would do, in a Land that has been expoſed to the Air, Froſts, &c. by the good Digging that has been given it, when the Ridge has been dug with the Spade the whole Length.

This ill Manner of Planting with the Pick-axe, retards a Vineyard from four to five Years, and oftentimes the greateſt Part of it dies: But this ought not to be ſurpriſing, for this Land not having been turned topſy-turvy, nor expoſed to the Air and to the Rains, which furniſh the Salts neceſſary to Vegetation, it is impoſſible it ſhould ſucceed, eſpecially when it has not been often and plentifully dunged.

Although the Ridges are ordinarily compoſed but of two Rows, nevertheleſs there ought to be planted a third about the Middle of each Ridge, according to the Proportion of the Planting; and if one has not Plants enough to finiſh intirely this third Row, the ſame Year that the Plantation is made, it may be done the Year following.

It is very neceſſary to have this third Row, for it ſerves to fill thoſe Places where the Plants are wanting in the Rows.

When one has a Deſign to plant a Vineyard under great Trees, or in Places more ſubject than the others, to the Froſts of the *Spring*, or to Blighting, &c. he muſt, in thoſe Lands proper for *Auvernats*, put the black *Formente*, becauſe they will better reſiſt the Accidents that often happen to a Vineyard, and will produce more Fruit; and when a little Wood is left, its Fruit will ripen as well as the *Auvernat*, of whatſoever kind it be.

It is true, the black *Formente* has little of the good Quality of the fine Wines, and for this Reaſon it ought to be planted apart, and not to mingle it with the *Auvernat*; for it is better to have Regard to the Quality than to the Quantity of the Wine.

Among the White Vines one may plant the white *Auvernat* of the *Low Country*; this Plant produces Wine ſufficiently good, provided it be ſet in a Land agreeable to it.

It will be proper for thoſe who have many Acres of Vineyards to improve, to have one Part of young, and one Part old; becauſe if one Year prove contrary to the one, it may be favourable to the other; and then neither will the *Vigneron* be ſo hurried in the Seaſon of Pruning them, nor will the Maſter be ſo embarraſs'd when he gathers his Vintage; for if his Vines were all young or all old, he will be oblig'd to gather them both at the ſame Time, if they have been planted in a Place where the Soil is of the ſame Nature.

Of the Care that ought to be taken of Plants.

To do this that the Plants may ſucceed, it is not ſufficient that the Plant be well choſen, the Land well prepared where it is to be planted, and the moſt convenient Time taken for Planting it, but there are ſtill many things to be obſerved.

In the *firſt* Place, the Plant ought to be pruned eight or ten Days before it begins to put forth, becauſe then the Buds being pretty large, it is eaſy to diſtinguiſh the Good from the Bad; which ought always to be done in ſuch manner, that one good one may be at the Superficies of the Ground; and when it is found that that which has been left doth not put forth in its Time, you muſt ſoftly with the Hand unearth the Cutting unto the firſt good Bud, that it may be expos'd to the Air, and may put forth the more eaſily; for if the Bud be not cleared of the Earth, the Cutting may rot therein; and a great Failure will be avoided in uſing this Precaution.

Secondly, To water the Plants, and that ſeveral times, when the Heat is violent and continual. The firſt time when they are planted, and when the Ground appears dry, and the Seaſon diſpos'd to be windy; the ſecond, eight Days after: in caſe that the Heat continues, one may give to each Plant three Pints of Water, and this ſhould be poured equally upon every Part of the Plant.

The firſt Time the Plant is watered, it is good to do it when it is not above half covered with Earth, to the Bud, that that Part which is loweſt may be freſh and moiſt, that it may take Root the more eaſily.

Theſe Plants ſhould not be watered with any but Rain-water, which is the moſt natural to all Plants; but if that is not to be had, that of Ponds, Ditches, and Marſhes ſhould be uſed; but if inſtead of this Water there be uſed that which runs into a Pit from a Dunghill, it will have a very good Effect, for that is well furniſhed with Salts, and conſequently very proper for Vegetation.

It is true, it will be difficult to have enough of this for a large Extent of Ground, but it ſhould always be uſed where it can be had.

The Excellence of this Water will ſoon appear, by the Strength with which the Plant that has been watered with it will put forth.

The moſt proper Time to water, is in the Evening, towards the ſetting of the Sun, and the Day following in the Morning, you may lay ſome Mulch upon the Ground: This will hinder the Earth from chapping, and the Heat from penetrating too far into the Earth, where the Plant has been planted; for it will have more Need of Freſhneſs and Humidity, than of Heat and Dryneſs, eſpecially 'till ſuch time as it has taken Root, which may be known by its budding out.

Some look upon this as an unneceſſary Precaution, as to the Watering the Plants; but yet I am of Opinion, that there ought to be a Diſtinction made between freſh, moiſt Lands, where Watering may not be neceſſary; but it muſt be uſed to thoſe which are dry and burning, eſpecially when the Planting is done in the *Spring*, and ſometimes ſo late, that the Drought ſurprizes the Plants before they have taken Root. It is true, Planting is ordinarily performed before *Winter*, in ſuch Lands.

Thirdly, When the Plant begins to put forth, and the Heat is not too violent, you ſhould give it ſome labouring, eſpecially ſoon after Rain. In order to give them this Labour as it ſhould be, there muſt never be ſuffer'd among theſe Plants any Legumes; particularly Great Gourds, Peas, Beans, Turnips, Leeks, and eſpecially Cabbages, which will infect and impoveriſh the beſt Lands in a little time.

Of the Damage that Fruit-Trees *do to* Vines.

If Trees planted round about Vineyards don't fail to hurt them, as has been before remarked, there is no doubt but that they will prejudice them much more, when they are planted in them.

And altho' ſome Advantage may be made of Fruit-Trees, nevertheleſs they ſhould never be planted in Vineyards, becauſe they never do better than when they are alone, and well cultivated; and for this Reaſon nothing but Vines ſhould be planted in them, eſpecially not Peaches or wild Quince-Trees; which ſhould rather ſerve for Hedges, than to make Profit of; for theſe Trees planted in a Vineyard, eat and dry the Earth as far as they reach, and the Grapes that are under them have always leſs Taſte, and ripen with more Difficulty than the other; becauſe theſe Trees ſhade them, and hinder them from enjoying the Heat of the Sun, and the beneficent Influences of the Heavens.

And beſides, when the Seaſon of the Maturity of theſe Fruits approaches, and alſo oftentimes before that Time, the *Vignerons*, their Wives, their Children, *&c.* fling at the Pear-Trees, Props which they pluck from the Vineyard, which cannot be done without breaking a great many Shoots, and the Props bruiſing the Grapes, and ſpoiling the fallow Ground all round about theſe Trees, by trampling it.

If a Perſon will have Trees in his Vineyard, he ſhould plant none but *Winter* Fruit, becauſe theſe are commonly not gather'd 'till after the Vintage, then there would be fewer Inconveniencies to be feared; but yet it would be better to plant them any-where elſe than in the Vineyards.

Walnut-Trees ought never to be planted in a Vineyard; for they are the moſt prejudicial of all.

The Oſier alſo does great Injury to Vines, and eſpecially when it has a large Stock; becauſe being very large, the Roots muſt alſo neceſſarily be large, and extended in Proportion, which without doubt is prejudicial to Vines; for thoſe which are near to theſe Stocks, have commonly ſlender, corrupted Wood, and bear very little Fruit, and that bad-condition'd.

Of the Gathering the Vintage.

The Vintage of the *Auvernats* being the moſt precious of all thoſe which we have to make in this Plot of Vineyards; in order to have good Wine, we ought to attend the Maturity of the Grapes.

And as there are certain Soils, where the Grapes having been cut a little too green, are too much fermented in the Vat, and others, on the contrary, cut very ripe, are but little fermented, which keep the better; it is abſolutely neceſſary, that thoſe who have thoſe Vineyards do carefully apply themſelves to be acquainted with the Quality of their Ground.

But one may ſay in the general, of all the good *Auvernats* of this Country, that they ought to have always one Point of Green when they are gather'd, particularly when the Year has been hot, and the Lands where they grew have been fat, or very much dunged: For it is not ſufficient, when one would have good Wine, to cut the Grape in its Degree of Maturity, but he muſt take a fit Seaſon to do this in: as thus; one ought neither to begin nor continue to gather when it rains, though many are not very ſcrupulous as to this Point; for they ſay, the Wine will ſell never the worſe for it.

I own that it may ſometimes happen ſo, but it ought to be allow'd me, that it has a bad Quality. One ought alſo to ſee to it, that the Dew that falls often very plentifully in this Seaſon, be intirely diſſipated, and that there be no Dew either upon the Grapes or the Leaves of the Vines; for it is found by Experience, that for the little Quantity of Water there is in this Sort of Wine, it loſes a great deal of its Quality.

Therefore the Seaſon cannot be too fine for cutting the *Auvernats*, for this Reaſon; in a great many Vineyard Plots in this Kingdom, as in *Burgundy*, and other Places, where the Wines have ſo great Reputation, they don't gather their Vintage, but during the fineſt Part of the Day; that is to ſay, the Gatherers begin their Work very late, and leave off ſome Hours before Sun-ſet, and the Wine is the better for it.

It is true, that ſometimes it is good to wait for the falling of the Rains; but this ought to be ſome Weeks, or at leaſt many Days before the Vintage, and not in the Time of Gathering.

As for Example: When no Rain has fallen for a long Time, and the Grapes have been ſo ſhrivell'd by the Heat, that there is ſcarce any thing but Grape Stones, and a tough, thick Skin; if one ſhould gather them then, they would yield but very little Wine, and alſo it might turn to a Tartneſs, as it happened for the moſt part, to the Red Wines of the Year 1718, which were extraordinary hot and dry.

So then we ought not to gather the Grapes ſo ſoon as the Rain that we have waited for is fallen, becauſe the Grapes ought to have Time to have the Advantage of it, which may be known when the Berries grow large, and fall upon the Ground.

As to the other plants red or white, they may be gather'd with leſs Precaution; but they muſt always have their Degree of Ripeneſs, according to the different Lands on which the Vineyards are planted.

When there are found among the *Auvernats*, Vines whoſe Grapes do not appear to be ſufficiently ripe, or of a different Kind from the reſt, theſe ought to be left, that they may grow riper; and theſe muſt not be put but in the laſt Vat, or be mingled with the other Wine of a worſe Quality: This cannot but render it the better, as well as the *Auvernat*, becauſe it will be finer; for it will be the more worth in having a little the leſs, and not to be made with any thing but *Auvernats*, and alſo thoſe well-condition'd.

Becauſe there are green Grapes that the Vintagers ought not to gather and mingle with the others; they ſhould be expreſly forbid to put into their Baſkets, either thoſe that are green or rotten, for the one would make the Wine eager, and the other give it a rotten Taſte; which two Faults are equally to be avoided.

Of the Wines made in Orleans.

For a long Time, at *Paris* and other Places, there have been thoſe who have endeavoured to decry the Wines of our Vineyard Plots, eſpecially the Red Wines. In the mean time it is obſervable, that thoſe who ſpeak of them with the greateſt Contempt, can't do without them, but procure them as they did formerly, either to put off their weak Wines, without Colour, or that have ſome other Faults, and alſo to preſerve the fineſt, moſt delicate, and moſt celebrated.

For the Wines of *Burgundy* are no ſooner brought in, than they mix them with our Wines, to drink them, ſo long as they laſt; and there is this to be ſaid of our Wines, that there is not one ſingle Wine-Merchant at *Paris*, who has not our Wines in his Vaults, not only for mixing with others, which are much meaner, but for ſelling without any Mixture: For tho' they have much Strength, yet, for all that, they do not fail to ſell them pure, as well for their Tables as their Offices, to thoſe that have the Curioſity to drink a Wine that is good, natural, and without Sophiſtication.

The Rapes which are yearly made, and the great Quantity of Wines, both Red and White, which they are ſo ſolicitous to purchaſe a long Time before they are made, in order to tranſport them from *Paris* into *Flanders*, *Holland*, and *England*, and as far as the *American* Iſlands, where they drink good to the very laſt Drop, are, in my Opinion, ſufficient Proofs, that our Wines are not ſo contemptible as they would repreſent them.

For it muſt be own'd, that if they had not ſuch good Qualities, or if they had any Fault, they would not come in Search of them ſo far, and would not take ſuch Care to furniſh themſelves with them in time.

Some ſay, that our Wines being harſh, red, and too violent, they are not ſo agreeable to be drunk, and that thoſe that drink them to any Exceſs, find themſelves incommoded, which never happens to them when they drink the ſame Quantity, or even a greater, of the Wines of *Champaign* and *Burgundy*, and many other Vineyard Plots of the Kingdom.

I anſwer, that theſe pretended Faults are the real Qualities of our Wines, and thoſe are what cauſe them to be ſought ſo much after, for this very Colour and Harſhneſs (provided that it be not too much fermented in the Vat); for this ſerves to give a Quality to other Wines that are weak, which would never be vended to any Advantage without being mixed with others.

Beſides, if the Harſhneſs of them, which they ſometimes have, be their Fault, this is not always ſo, 'tis but accidental, and may be prevented, by letting them remain leſs Time in the Vat.

As for the Inconvenience that thoſe are ſenſible of, that drink too much of it, it is a very eaſy Thing for them to remedy that themſelves; they need only drink leſs of it, and then it would not incommode them.

As for Example: *Aqua vitæ* is not drank in ſo great a Quantity as Wine, nor a ſtrong Wine as a weak one; when the Wine is very ſtrong, they ought to drink Water with it, or drink leſs of it, then it would nouriſh a Perſon, inſtead of wearing his Body, or ſtupifying his Spirits. Thus, when one is ſenſible of any bad Effects from our Wines, it is not from their Quality that they proceed, but from their Quantity, which People know not how to uſe rightly.

If any of our Wines are undrinkable, this will not be always, but only for a Time; becauſe, if theſe Wines which have ſo much Harſhneſs, Colour and Strength, are not good to drink at one Time, it is certain they will be good at another, according to the Degree that they have been fermented in the Vat.

But this Fault is not in the Wine, ſince it needs nothing to be done to it, but to give it leſs of the Vat. It is alſo a great Advantage to our Vineyard Plots, that there they can make good Wine fit to drink as ſoon as it is made, and which alſo will hold good many Months, nay, many Years after: Thus, when ſometimes they ferment but a ſhort Time ſome of our Wines, and leave others there to force, this contributes, I confeſs, to render them very harſh; but this Harſhneſs, inſtead of taking away their Quality, only ſuſpends it, ſeeing that they become good after a certain Time.

Such are the Wines of *Gallinois*, of *Neuille a Bois*, of *Acheres*, &c. which do not become fit to drink till fifteen or eighteen Months after they have been made; yet they there make, off Hand, Wine that may be drank a Month or two after it has been tunned; but then this Wine is not drank in its Perfection: For the beſt of the Wines of theſe Places are ſuch as have been fermented in the Vat: In all Likelihood, the Lands where theſe Vineyards are planted require it. That which I call fermenting in the Vat, is the letting them ſtand eight or ten Days therein, and ſometimes more, but they muſt have as much Time as is neceſſary, to the end that their Harſhneſs may go off.

It is true, we don't always buy Wine with Intent to keep it long; but it is as true, that ſometimes we would have what will keep a long Time. The having much of the Vat then does not take away the Quality from theſe Sorts of Wines, ſince it only ſuſpends it; as I ſaid before.

Whatſoever ill-founded Prejudice may be taken up againſt the Wines of our Vineyard Plots, it muſt nevertheleſs be allow'd, that we have the Advantage over the greateſt Part of other Wines; that we are able to make them ſuch as we would have, and ſuch as are demanded; that is to ſay, a delicate Wine fit for preſent drinking, red without being harſh, a little hard, and ſometimes a great deal, and yet without loſing its Quality; and thus we are able to make a Wine equally good to drink thro' the whole Courſe of the Year, and alſo for many Years after.

But on the contrary, is it not a great Fault in certain Wines, in that they cannot be kept good for the Space of one Year? For one of theſe Tuns is ſpoiled before it is half empty; alſo the ſame Accident happens to it, when being full, the Heats ſurprize it before they have put it into the Vault, for theſe Wines don't ſpoil but when they are delicate, weak, and when they have been ſcarcely tunned; and if they ſhould be tunned any more, they would become harſh, and entirely loſe that little Quality they have in the Vat.

There are in this Kingdom many Vineyard Plots, the *Vines* of which have this bad Quality; and yet theſe are the Wines that are ſo much boaſted of, which will not keep the Year without ſpoiling, if they were not preſerved by ours, which have more of the Quality than they.

But if thoſe who put ſo great a Slight upon our Wines, ſhould ſay we do not know how to make them, they would reaſon more juſtly than they do, when they would have us to believe that our Wines are not good; for they ought to allow that they are good in themſelves; and we ſhall agree, that if there is any Fault in them, it is by Accident, ſince it only proceeds from the Manner of making it.

Then it muſt be ſaid, that the Wines of *Orleans* are good, but that they make them ill: And then there is nothing more wanting, but to avoid the Faults in the Manner of making, and that is what I am going to treat of.

We have in this Plot of Vineyards ſo many different Sorts of Soils and Plants, that it would not be eaſy to give a Direction for the Manner of making the Wines from each of them: I can only ſay in the general, that in order to make good Wine, the Soil ought to be proper for the *Vines*, well expoſed to the Sun, on a gentle Declenſion from the North to the South, rather dry than moiſt, that the Plants ſet there be of a good Kind and well choſen; that the Vineyard be rather old than young; never dunged, or but very little, but rather earthed, and always well wrought, and in the proper Times to work them; and that the Grapes have a certain Degree of Ripeneſs before they be cut; and that they be tunned after they have been trodden, when one would make Wine that ſhould have a Colour, and not for preſent drinking.

It is certain, that when all theſe Things concur, it will be eaſy to make good Wine: But there are yet other Things to be obſerved, of which I ſhall ſpeak in the following Part of this Article.

They make in this Plot of Vineyards, as well as in many others, both red Wine and white. I ſhall ſpeak firſt of the red, and afterwards of the white, of which there are a few Things to be ſaid.

The beſt and moſt precious Wines of all that are made in this Plot of Vineyards, is the *Auvernat*. Of this there are ſix Species, *viz.* the *Auvernat Teint*, the *Black*, the *Red*, the *Grey*, and two Kinds of *White*; which are the *White Auvernat* of *Solers*, and that of the *Low Country*.

The *Auvernat Teint* is the reddeſt, and as it has alſo the Quality, it gives the Colour and the Body to the other *Auvernats*, and prevents them from growing ropy; and when it is mingled with the red only, they ought to let it remain in the Vat a little while, eſpecially in thoſe Years that there is Reaſon to believe the Wine will take as much Colour as they would it ſhould have, or where it grows on a Soil where the Wine has always been accuſtom'd to have Colour enough by being tunned but a little.

Some pretend, that one Quart, or thereabouts, of the Wine [*de Teint*] of the Tincture, or of [*gros Noire*] the large black, to a Vat of fifteen Puncheons of red *Auvernat*, will have a good Effect.

I own that it will give it a fine Colour, without rendering it harſh, provided it be not tunned too long; but as this *Teint*, or this *gros Noire*, have no Quality but that of giving it the Colour, I am of the Opinion that the *Auvernat Teint*, which is very red, ſubſtantial and vinous, produces a better Effect: But it requires only to put more of that of the *Teint* than of the *gros Noire*, becauſe the *Auvernat* colours a great deal leſs than thoſe two Kinds of Grapes.

The riper both the one and the other are, the more Wine they yield, and the more Colour they have; and for this Reaſon they ought never to be gathered but when they are in their perfect Maturity.

The *Auvernat Teint* ought not to be planted indifferently in all Sorts of Lands, becauſe it will not do well in all; and for this Reaſon, thoſe who would have them, ought at firſt to plant but a few, to ſee if they will ſucceed in their Lands: Alſo Care muſt be taken not to mingle them with others in planting, that one may the better know what Quantity we ſhould put into every Vat, which will be difficult to do, if they were planted confuſedly with other *Auvernats*, or red Plants, to make thence good mix'd Wine.

Although the *Auvernat Teint* is a very good Grape of itſelf, yet it muſt be owned, that if too much of it be put into the red *Auvernat*, it will alter the Quality of it; for the laſt Wine is never better than when it is made without any Mixture of other Grapes; and it has ordinarily as much Colour and Strength as it ſhould have, not only to maintain itſelf by itſelf, but alſo to put off other Wines of a leſs Quality.

But then I ſuppoſe, that this red *Auvernat* grew upon good Lands; for there are ſome which of themſelves do not give enough to the Wines that they produce: In this Caſe it is good to plant the *Auvernat Teint*.

It is true, that this Wine being mixed, will not be ſo fine, as if it were only the pure red *Auvernat*; but then again, it will maintain itſelf better: And when one would make an *Auvernat*, which has a ſtrong Tartneſs, and a good Flavour, without having any Colour, you muſt put to the red *Auvernat* about the ſeventh Part of the *Melier*, or of good white *Auvernat*, ſuch as now grows in the Vineyards of *Blois*: But that one may be able to make this Mixture, it is neceſſary that this *Melier*, or white *Auvernat*, be ripe at the ſame Time as the red *Auvernat*.

A Wine made after this Manner, is ſo excellent, and ſo diſguiſed, that it is made to paſs for pure *Burgundy* Wine, and is ſold at *Paris* and other Places as ſuch in wickered Bottles: The beſt Wine-conners are there deceived every Day.

The *Auvernat*, without Diſtinction, is red; they alſo name it from its Skin, which is brown, becauſe its Colour is not of ſo deep a red as that of the *Auvernat Teint*, and becauſe it is deeper than the *Grey Auvernat*, which is almoſt quite white, and that too when it has been tunned very much. This Kind of red *Auvernats* is the moſt common among the black *Auvernats*, and one of the beſt Wines that grows in this Plot of Vineyards.

The [*Auvernat Noir*] *Black Auvernat* is very uncommon in this Country, and known by few Perſons; its Berry is rounder than the other *Auvernats*; its Skin is as black as Jet, and that is the only Thing that it is known by: There is alſo another Species of it, which ſome *Vignerons* call the *Auvernats* of *Touas*; it differs nothing from the red, but in that its Wood is very big, as well as its Fruit. The Grape is long and well filled; and it were to be wiſh'd, that this Kind was not ſo ſcarce in this Country, for it is the fineſt, and one of the beſt that we have.

The *Grey Auvernat* is neither white, nor black, nor red, but of a grey or pearly Colour when at the greateſt Maturity. But ſome have made this Obſervation, that in certain Lands this Colour becomes black in about twelve or fifteen Years after the planting of theſe *Vines*; but nevertheleſs without loſing their Quality. The Change of the Colour does not come univerſally. I have ſeen Vineyards very old, that did produce the *Auvernat* of this Quality.

This Grape having a very good Taſte, makes alſo an excellent Wine, and, I am of Opinion, the beſt of all the *Auvernats*; but it is good to give it a little of the green, eſpecially when it grows in very good Lands, becauſe this Wine having a very good Body, its Greenneſs falls by little and little, which at the ſame time augments its Strength; and it is the green that they give it that ſuſtains it, and hinders it from growing ropy; for theſe Wines that are not tunned, or that are but a little fermented, are very ſubject to be ropy, at leaſt if the *Vines* do not grow in flinty Lands; nevertheleſs they are ſometimes ſubject to be ſo in ſuch Lands, but indeed not ſo much as the others.

When this *Grey Auvernat* has been made off-hand, or when it has been tunned but a very little while, and it is once gone from this Vineyard Plot, and is denominated by a borrow'd Name, it is an eaſy Matter to make it paſs for ſuch a Wine as is deſired, whether it be ſold as it is, or whether it be mingled with others of a higher Colour. But this Mixture muſt be made in ſuch Manner, that the Quantity of the *Grey Auvernat* be not abſorb'd by the Red that is mix'd with it.

It is not proper to let the Place be known, where a Wine, made after this Manner, is gathered; for if it were known that this Plot of Vineyards of *Orleans* produced it, there would need nothing more to make it loſe all its Merit in the Opinions of thoſe who ſuffer themſelves ſo eaſily to be prejudiced againſt our Wines. When this Wine is made without any Mixture, then one perceives all the good Quality; and when it is cut with the *Auvernat Teint*, it is indeed leſs fine, but it keeps the longer, and is not ſo ſubject to grow ropy. And when the Red *Auvernat* is mingled with theſe two other Species of *Auvernat*, this makes one of the beſt Wines that can be drank, and it will keep without Harſhneſs, becauſe this Grey *Auvernat* has a Fund of Delicacy which allays the Harſhneſs of the *Auvernat Teint*, and this by its Firmneſs ſuſtains the other, and makes it keep the longer.

Many *Vignerons* do not know at all, and others feign that they do not know, the true Grey *Auvernat*; and the one from Malice, and the other thro' Ignorance, confound it with a certain Plant, which they call *Grey*, or the *Miller's Wife*; but this is a black *Formente*, or *Bourguignon*, which is nothing of an *Auvernat*.

This Plant is one of the leaſt that is in this Vineyard Plot, yet many plant it, becauſe it produces a great deal of Wine, and becauſe it reſiſts the Froſts of the *Spring-time*, and the other Accidents that happen to Vineyards, better than other *Auvernats*. And this is the Reaſon, one may ſay, that this Plant is a true Drudge; and it is without doubt for this Reaſon, that thoſe who have it, always gather more Wine than others who have it not; but as the Quality of the Wine is not in this great Quantity, it is ſeldom that this Wine comes too good; for five or ſix Months after it has been made, it grows flat, tart, without Colour, and alſo is ſpoiled, by reaſon it is not put into a good Vault before the firſt Heats of the Spring of the Year, becauſe oftentimes the firſt Clap of Thunder turns it. Nevertheleſs the Merchants furniſh themſelves with this Wine, becauſe it is cheaper, and has a certain Headineſs, which the *Auvernat* has not, unleſs it be two or three Months after it has been made.

In planting this wretched Plant we have found out the Secret of ſpoiling the beſt Places of this Vineyard Plot. As for Example: About forty or fifty Years ago, the Wines of *Paroiſſe* and *Bou* were very much in Requeſt; but ſince that Time almoſt all the Vineyards in this Territory have paſſed out of the Hands of the Citizens, and fallen into thoſe of the *Vignerons*, who commonly do not regard any thing ſo much as the Quantity, and therefore have indiſcreetly planted ſo many Vines of this black *Formente*, that now the Wines of this Place are much neglected, and ſought for elſewhere.

But nevertheleſs we are not to believe that our Soil has changed its Nature, as ſome Perſons falſly imagine: without doubt it is ſtill the ſame; and to render this that I ſay the more certain, if we taſte the Wines of thoſe who have nothing but the pure *Auvernat* in their Vineyards, I am ſure we ſhall find them as good as the beſt *Auvernats* of this Vineyard Plot.

If the greateſt Part of the Wines of this Place are not ſo good as they ought to be, it ſhould not be attributed to the Ground, which cannot change, but to the bad Plants that have been planted there: and it is to be fear'd, that in Proceſs of Time the ſame Inconvenience may happen to other Places, whoſe Wines have at this Time a great Reputation, becauſe they have effectually a good Quality; and they will keep it, as long as the Citizens ſhall not have the Itch of planting the wretched black *Formente*.

It may be ſaid, that many Commiſſioners and Wine-Merchants have given Occaſion to thoſe who deſtroy or renew their Vineyards, to plant there the black *Formente*, becauſe they would not always acknowledge the different Quality of Wines by the Difference of the Price.

This, I ſay, has been the Reaſon that determined the Citizens, as well as the *Vignerons*, to regard the Quantity more than the Quality of the Wines. But they are much to be blam'd for this, becauſe they thereby depreciate their Eſtates; for they muſt needs know, that in thoſe Years when there is abundance of Wines, as frequently is the Caſe, a Search is always made after thoſe that are beſt; and ſo the Wines which are found to have the Quality are ſold, and thoſe that have it not are left in their Hands.

Of

Of making Wine in Orleans.

The Grapes being cut and carried from the Vineyard to the Preſs, they tread them either in a Scuttle, which they place there, or in a Vat when the gathering of the Vintage is finiſhed; or, in fine, they caſt them into a Trough of a Wine-Preſs to be bruiſed. Alſo ſometimes they carry them directly to the Preſs; but this is when they would make Wine fit for preſent drinking, and that it is not fermented in the Vat at all.

Thoſe who make uſe of a Scuttle to bruiſe their Grapes, can't poſſibly tread the Grapes well, or at leaſt they will be a long Time in doing it, and have a great deal more Trouble, in that they are obliged to raiſe up with all their Strength, the Puncheons that they tread, to caſt them into the Vat with the Marc, in order to work it all together.

The Manner of bruiſing the Grapes in the Vat when it is fill'd, is much worſe than the firſt; in that notwithſtanding all the Precaution that can be taken, and whatever Time is allow'd to endeavour to do this Work well, it is abſolutely impoſſible it ſhould ſucceed well; for when the Wine has been tunned as much as it ought, and they have put it on the Preſs with its Marc, there will be a Part of the Grapes that have not been half bruiſed, and this cauſes the Marc to yield leſs Wine, and there is not all the Colour that it might have, and therefore the Grapes ought never to be bruiſed this Way when it can be done otherwiſe.

But if this is a Loſs to the Citizens, not to draw from the Marc all the Wine which it ought to yield, if all the Grapes had been well bruiſed; yet it affords an Advantage to the *Vigneron*, in that his Drink will be ſo much the better.

As there is an Inconvenience in treading the Grapes, either in a Scuttle or a Vat, as I ſhall make appear, it will be better to make uſe of a Trough for a Wine-Preſs; this is, without Contradiction, the beſt way to bruiſe the Grapes.

And beſides, a Wine-Preſs Trough will ſerve for four Panners, when the other will not ſerve for two, if they make uſe of a Scuttle; for according to the Meaſure that the Grapes are bruiſed in the Wine-Preſs Trough, the Wine falling into the Vat does not riſe above the Grape, by which it may be more eaſily known whether the Grapes have been well or ill trod before the Marc is turned into the Vat; or it is a great deal more eaſy to puſh it with the Foot, when the Trap Door of this Trough is lifted up, than to lift it up thence with bodily Strength, as they are obliged to do, when they tread in a Scuttle.

This Trough ought to be ſet in a kind of Litter, and placed upon or over the Vat; but when the Covering of the Structure where the Preſs is, is low, it muſt be placed over the Middle of the Preſs without a Litter; then there will be a little more Trouble, becauſe it muſt be emptied into the Vat with a *Bucket* or Scuttle; but this is no great Matter, there are Hands enough to do this Work.

The Grapes having been trodden, as before, the Marc may be thrown into the Vat, either with the Grape and Skins, or ſeparated the one from the other: This depends on the Manner after which one would make the Wine.

When the Grape is tunn'd with the Skins and the Wine, it may produce two different Effects, the one of which will be good, and the other bad.

When it has been tunn'd a conſiderable Time the Wine is leſs green, leſs ſubject to be ropy, and better for keeping, than if it were done off-hand, or fit for preſent drinking.

But if the Grape be tunn'd too much, it takes from it much of its Quality, becauſe it leaves a Harſhneſs, which renders it not fit for drinking for above a Year in certain Lands, and in others it never loſes the Taſte of the Grape-Stone; and when with this Exceſs of the Vat it has a Colour as red as Ox Blood, it is a Wine which they call *Groſſier* or *Matin*; and it is commonly ſaid it is better to keep than to drink.

When a Wine has this Fault, one cannot render it drinkable, but by mingling it with good dry new White-Wine.

Then it is this Exceſs of the Vat that renders our Wines hard, and makes them diſ-eſteemed without any Diſtinction, altho' all our Wines are not made after this Manner. But it is an eaſy Matter to avoid this Fault, which renders our Wines contemptible.

There are thoſe who tun the Grape-Stone with the Skin, and would give to their Wine only that Degree of the Vat, which it ought to have, not to be ſtrong, do draw it out from time to time by a Pipe, or by ſome little Hole which they make in the Vat; but this I do not approve of, for Reaſons to be given in the following Article.

Others make uſe of a Vine-prop, or ſome other Piece of Wood, which they thruſt into the Vat, from whence they draw it out quick, and let it drop into a Glaſs, where they examine if it have Colour enough, and if it makes a Circle of Scum, and boils and bubbles, which they call *faire la roüe*: Others watch till the Marc is riſen to ſuch an Height, and make a Judgment by that.

As for my ſelf, I am of the Opinion, that it would be a ſurer Way to thruſt one's Hand a pretty Way into the Vat, (which I ſuppoſe to be rais'd and to have been work'd) to take from thence a handful of the Mark, and to put it to one's Noſe, as the Dyers do, to judge of the Diſpoſition of their Vats; then one may know if the Wine be made, and if it has Colour enough.

When it ſmells ſweet, you ſhould let it work a little longer in the Vat until it has loſt that Smell, and has a ſtrong Scent that affects the Noſe: then it ought to be taken; for one Quarter of an Hour at moſt is ſufficient to force it.

A Wine taken in its proper Degree of the Vat will never taſte of the Grape-ſtone, it will be always fit to drink, and alſo will keep good for many Years.

I agree alſo, that the Wine that has been tunned too much, becomes tart and harſh, and that that is what takes away its Quality; and as it is the Grape-ſtone and not the Skin that cauſes this Tartneſs and Harſhneſs, the Means to prevent this Inconvenience, is in being very careful as to the Degree of the Vat that is given to the Wine.

But as one may often be deceiv'd in giving it too much or too little of the Vat, I think the ſureſt Way would be, to ſtone the Grapes when they are trampled, before they are put into the Vat.

This Work would not be ſo much Trouble as it may be imagined, for one Stoner would ſuffice to employ one Treader, let him tread as faſt as he can.

When the Grapes are bruiſed in a Wine-preſs Trough, ſeveral may employ themſelves in ſtoning: One Method of doing it is, to put them into a Basket plated, &c. about ſix Feet long, four Feet broad, and ten or twelve Inches high: And that this may not be any Incumbrance, it may be plac'd about the Middle of the Preſs, and have two Men to ſift and ſeparate the Skins from the Grape-ſtones.

I find that a Cribble is much more convenient, for it takes up leſs Room, and there needs but one Man to work above, and the Work will be as eaſily or more eaſily done.

I have ſeen many of theſe Cribbles; but that which I am going to deſcribe, appears to me to be the moſt commodious.

The Cribble for ſtoning the Grapes ought to be made with Braſs-wire, becauſe that is more pliant, and does not ruſt ſo much, and laſts longer than Iron-wire. The Holes ought to be an Inch in Breadth, almoſt of an octagonal Figure; it is work'd upon two Hoops join'd together, the one upon the other: and when it is finiſh'd, it is to be cover'd with a third Hoop or Band, that is about four Inches high.

As the Marc is in falling, and the Wine being preſſed out, and that it is caſt in the Height of the Cribble, they put under it, to ſuſtain it, a Band of Wood or little Hoop two or three Fingers high, which goes round at the Bottom of the Cribble, and beſides this, four Iron Bars of the Thickneſs of a little Finger, becauſe if they were broad, the Skins of the Grapes would reſt there, which would hinder the other from paſſing.

It is proper to put theſe Iron Bars in ſuch a manner, that two of the four may ſuſtain the other two, and that they be all of the ſame Length.

The Ends ought to croſs the two Hoops, and to cover the third, and they muſt be join'd to many Places of the Trellis with a Braſs Wire, which may be double or treble.

The Wood of the Hoop ought to be notch'd in two Places over againſt one another, and about an Inch in Depth, and three in Breadth, according to that of the Staves upon which it is to be plac'd; and theſe Staves ſhould be plac'd upon a Scuttle reſting upon the Vat, above which they tread the Grapes.

It is alſo proper that theſe Notches be plated with Iron, and that they have two Handles or Graſps of Iron pretty thick and round, to prevent the hurting the Hands of him that manages the Cribble, becauſe it is weighty, and there is Occaſion to remove it from Place to Place.

This Cribble may be about a Foot in Height, eight or nine in Circumference, and an Inch in Thickneſs at the Top, and ſomething more at the Bottom, becauſe of a Band of Wood that is plac'd round about to ſuſtain the Trellis, as I have ſaid before.

The Treader having bruiſed the Grapes, inſtead of puſhing the Maſs in the Vat with his Foot, as is done when he would tun the Grapes with the Skin, it is taken either with a Bowl or a Pail, or with the Hand, and put into the Cribble; then the Stoner ſeparates the Marc, as well as he can, the Skin from the Stone, and caſts the latter into a Veſſel that ſtands near him: and when that is fill'd with the Grapes, they carry it to the Middle of the Preſs in a Pail, or in a Baſket, and from time to time empty into the Vat (to which the Stoner is very near) the Skins and the Wine which are in the Veſſel above, which has been ſtoned.

The Buſineſs of the Vintage-Gatherers being finiſhed, they put the Marc and all the Stones that are upon the Middle, and they lower the Plank to draw from thence the Wine that is found there.

Some give it another Bruiſing, but I believe very unprofitably; for that can't get out much Wine; and alſo that which they get from theſe Stones has nothing but a Harſhneſs, but nevertheleſs one may, becauſe there is a little of it, mingle it with the other, that is in the Vat.

One Marc of Grapes, which one may reckon ten *Poinçons*, may yield about fifty Pints of Wine or thereabouts. This depends upon the Size of the Grapes, and the Heat which has been during the Time of the Vintage-gathering.

The Wine being boil'd with its Skin, it will be neceſſary to obſerve, from time to time, if it have Colour enough; and if it be ſufficiently made, to be taken off: and when it is found that it is not yet red enough, the Marc muſt be thruſt down in the Vat in order to give it the Colour, and never to be forc'd: You may alſo cover the Vat with a coarſe Linen Cloth double, and put the Board of the Preſs upon that, in caſe one is apprehenſive that it will loſe a Part of its Strength.

It is not the ſame, when the Stone is left to tun with the Wine, becauſe it can eaſily force; whereas this Inconvenience never happens when the Grapes have been ſton'd: For this Reaſon it ought always to be done; one is ſure to have Wine well made, and ſuch as may be kept many Years without ſpoiling, according to the time that it has been left to ferment.

And if all our Red Wines were made in this manner, we ſhould not have occaſion to ſay, as it hath been ſaid for a long time, that our Wines are harſh and coarſe; for it muſt be agreed, that it is nothing but the Stone that gives it this bad Quality, which is, however, accidental, ſince I have offered a Method to remedy it, which may eaſily be put in Practice.

Many Citizens complain, that the Merchants won't give a greater Price for the Wine whoſe Grapes have been ſton'd, than for that which has not; but, in the mean time, it is better: It does indeed coſt ſomething more in making it after this manner, in that it takes up more Time in preſſing.

Upon this Account many Citizens have diſcontinued the ſtoning their Grapes; but I do not approve of that: we ought to ſpare nothing to make good Wine; and I am perſuaded that there will always be found Merchants reaſonable enough not only to make a Diſtinction between a Wine, the Grapes of which have been ſtoned, and that which has not, not only by their Taſte, but in the Price too.

As the Grapes that are fermented without their Stones, are ſubject grow ropy, it is good to prevent this Inconvenience in gathering them before they come to their full Maturity, and to give them but little Fermentation; it can then never be too thick, becauſe the Grape-ſtone not being there, it is impoſſible it ſhould force it.

During the Time that the Wine is working in the Vat, one may pierce the Casks, and put into each of them about a Pint of Water; it ſhould be boiling hot, or at leaſt very hot: This will purify the Veſſels, and render them more tight.

The Hole of the Bung being well ſtopped aſſoon as the Hot Water has been put in, it ſhould be ſhaken and turn'd on all Sides, to be able to ſee if it has Vent in any Place.

Some pretend that this hot Water will take away the Taſte of the Casks; but I very much doubt of this.

In order to make this Experiment, it is requiſite that one be firſt ſure that the Cask has any bad Taſte.

When the Casks have been ſeaſon'd and drain'd as dry as may be, they muſt be plac'd upon the Stilliers, and there ſet firm with Stones or ſome other Thing, to hinder them from rolling while they are filling.

The Baſket that is hung up by Means of a Prop to receive and hold the Grapes and Skins which fall from the Middle of the Preſs into the Wooden Pipe, ought to be well cloſ'd up to hinder the Stones from going into the Casks when they are filling, becauſe when the Wine boils, it caſts out the Scum, the Lee, the Skins and the Stones, in order to purify it ſelf, and ſometimes a ſmall Quantity of theſe is ſufficient to ſtop intirely the Holes of the Casks.

But to prevent this Accident, one may nail, at the ſmall Hole at which the Wine runs down, a ſmall Lattice of Braſs Wire, of which the Holes muſt be very fine: then there would but a few of the Skins paſs, and no Stones, and the Baſket, which is very troubleſome when one would empty the Pipe, would be uſeleſs.

One may yet, for the greater Security, have another Grate, and faſten it with Nails above the Socket on the Inſide of the Funnel; but this Grate muſt be raiſ'd three or four Fingers, to the End that the Skins may not hinder the Wine from paſſing.

Before the Marc is begun to be put upon the Middle of the Preſs, I ſuppoſe the Preſs to be in ſuch Condition that nothing is wanting of all the Utenſils that are neceſſary; for it would be an Imprudence to have at this very Moment any wanting that is neceſſary for the making of a Marc.

It is true, one may borrow of a Neighbour what one may want, but it may ſo happen that they may be uſing the Things at the ſame time, and that would be a great Diſappointment.

The Screw being the moſt brittle and moſt neceſſary Part belonging to a Preſs, a Maſter ought always to have one in reſerve, ready to be put in, in Caſe of Need.

In like manner, the Feet of the Beams ſhould be examined ſome time before the Vintage, that they be not rotten, for that is the Place they commonly fail in; and when this happens, it is not ſo eaſy to remedy it as it is to remedy a broken Screw.

In order to make the Beams of a Preſs laſt a long time, when they are good of themſelves, it ought to be ſo contrived that they may always have the Air under the Middle of the Preſs, eſpecially at the End of theſe Pieces there ought not to be either any Marc or Earth, and therefore it ſhould be hindred from falling there.

Some make a ſmall Piece of Brick-work round each of theſe Beams, and that is the beſt Precaution that can be taken to make them laſt a long time.

After the Preſs has been put in Order, and that the Wine has had its Degree or Time in the Vat, that it ought to have, or they can give it, it muſt be put upon the Middle of the Preſs.

When it is at a great Diſtance from the Vat, they make uſe of a Scuttle or Baſket, or if it be near, of a Pail: which they let drain upon a Board which bears at one End upon the Vat, where it is faſtened with a Nail or other Thing, and the other upon the Middle of the Preſs: This Board ſhould be bordered on both Sides with Ledges, ſtrait and well joined, and about an Inch in Height, to hinder what drains out of the Baſket from running on the Ground.

A Piece of Wood, with a Hollow or Channel about an Inch deep, would be much better than this Board with Ledges, for they can't be with Eaſe ſo cloſely joined, but that the Wine will find ſome Chinks to run out at, which will not be in this Wood thus hollowed.

Some, in order to empty their Vats the more eaſily, put in a Pipe, through which they draw the Wine clear through a little Bucking-tub made for this Purpoſe; out of which they take the Wine in a Pail or Pannier, to empty it into the Casks.

For this Purpoſe the Vat muſt be ſet high on a Stilling or Gauntry, and the Earth hollow'd at the Place where the Pipe is plac'd.

Before the Wine is drawn off clear, you muſt always begin to take off the Cover of the Vat, in order to prevent the Wine from forcing: and this muſt be done in ſuch a manner, that he who empties has not the Trouble of lifting it up ſo high to put it in the Scuttle or the Meaſure.

I own, that this Manner of emptying a Vat is very commodious; I ſhall, in the following Article, ſpeak of the Inconveniency that may happen thence.

The Marc being placed on the Middle of the Preſs, they cover it with a Board, with Bolſters, Cuſhions and Bags or Pillows: There muſt be two Rows of theſe laſt, and ſometimes three, when the Marc is thin, becauſe by how much leſs the Screw appears, by ſo much leſs it is in danger of breaking; and as the Marc ſhall be thick, according as they have ordered it, there muſt be ſome Rows of the Bags retrenched; for it is ſufficient that there is a certain Diſtance between the Wheel and the Screw, which would not be ſo if the Marc were very thick, or there were many Sacks.

There is no need to put the Ring of the Rope into the Hook before the Wheel has been lower'd on the Bags, and that you have examin'd if all is made even, and that none of the Bags are remov'd.

Before you begin to lower the Wheel upon the Bags, the Screw ought to be well greas'd above the Nut of it, and alſo below, when it touches the Bags.

They alſo greaſe that Part of the Screw that was within the Nut-ſcrew before they have brought it down to the Point where it ought to be; for the firſt Operation after the Plank of the Axle-tree has been let down, and before the looſening, the Screw muſt be ſoap'd on the Places where it has had none.

White dry Soap, without Oil, is the beſt for greaſing the Screw: When Oil is mingled with the Soap, that draws the Rats, who gnaw the Screw, and it occaſions a Gum or thick Subſtance, which makes it go hard when they preſs the Marc.

The Trendle ought alſo to be plac'd at a reaſonable Diſtance from the Middle of the Preſs upon the Nave of the Wheel; and being well rubb'd with Hog's Lard, the Trendle will turn the better: Others make uſe of an Iron Crow, which at leaſt produces as good an Effect as the Nave.

When the Staves or Rammers are rather long than ſhort, and that the Trendle is pierc'd with an Height agreeable to a Man of a middle Stature, they will have the more Force to preſs the Marc.

After the Plank has been let down, and the Troughs fill'd to a Pannier, or thereabout and they have afterwards added the Wine that comes from theſe Preſſings, they give the firſt Squeezing, which ought to be follow'd by three others in a ſhort time, becauſe the *Auvernat* having in it much Fire, its Marc would dry quickly, and yield much leſs Wine, if there were much Time between theſe Preſſings.

It is not enough to greaſe the Screw of the Preſs the firſt Operation before the Balance is let down, when it is a Wheel-preſs; it ought to be done from time to time, eſpecially when the Screw is perceiv'd to be rough, or ſcreaks in the Nut when the Trendle is turn'd.

Some, before they give the Marc the laſt Operation, *barbager*; that is to ſay, they work it, or prick it with an Inſtrument of Iron, but without touching the Sides, becauſe they chuſe to hinder it from falling on the Middle. They pretend that this little Squeezing makes the Marc yield about two Pints of Wine the Puncheon.

I have never made the Experiment; but this is ſeldom practis'd but in the Marcs of White Wine, becauſe they are thicker, and not ſo hot by much as thoſe of *Auvernat*.

The laſt Operation or Preſſing being given, you may wait twelve or fifteen Hours for raiſing the Marc, that it may have Time to drain; and they ſeldom raiſe it ſooner, except they want the Preſs for making other Wine.

Altho' the Wine that comes out of one Vat is the ſame, yet they give it two different Names: The one they call *Unpreſs'd Wine*, and the other the *Wine of the Preſs*.

The firſt is that which comes from the red or white Grapes, when they have been trod, whether they have been tunn'd or not; and the ſecond is that which comes from the Marc after the Preſſing. As this laſt has always a great deal more Colour and Harſhneſs than the firſt, they mingle them together, to the end that they may make an equal Wine; and if they do not do this, they would have one Part of the Wine of the ſame Vat too delicate and weak in Colour, and the other too red and too harſh, which would not be fit for the Merchants, who are for an equal Wine.

When I ſay the Wine ſhould be equal, I mean only that of one Vat, and not of one whole Cellar; for as all the Wine that one buys can't be all ſpent at the ſame time, and that the Merchants ſearch ſometimes for Wine high coloured and a little firm; and ſometimes for a Wine more delicate and fit for preſent drinking, therefore it is, in my Opinion, the Prudence of a Citizen to have Tuns of different Degrees of Colour and Firmneſs, that the more delicate may be drank firſt, and the firmeſt ſome Time after, or the Year following; for moſt Perſons love old Wine better than new.

But it is yet more advantageous for a Citizen to have Wine that is rather a little firm than too delicate, becauſe if that be not ſold quickly, it may grow ropy or be ſpoiled; when, on the other hand, that which is well mixed will keep a great while, and he may ſell it a long Time after.

It is true, the Merchants often ſlight, or rather ſeem to ſlight and reject a Wine that has been but little fermented; but it is very often nothing but a little Chicane that thoſe make uſe of who are employ'd to purchaſe Wines, to buy them the cheaper; therefore we muſt give them leave to ſay what they will; but always give the Wine ſomething of the Tun, becauſe if it be not ſold at firſt, it will at laſt: whereas, when it is made for preſent drinking, it muſt be ſold as ſoon as may be, and perhaps under Price.

Some Perſons out of Thriftineſs, or rather ſordid Covetouſneſs, fearing to loſe a little Wine, never intirely fill their Caſks till the Wine has caſt forth its greateſt Fire, that is, they won't make it boil till it has no Force left; and there being only one Pannier full of Wine put into the Caſk the next Day, or two Days after it has been filled, that has not the Force to warm it again ſufficiently to make it boil.

This way of managing Wine is very wrong for it cauſes all its Excrement to remain at the Bottom of the Caſk, which augments the Lee, and often contributes to the ſpoiling the Wine, and to keep it for a long Time foul, which therefore the Merchants reject.

It would be much better to fill it preſently up to the Bung with the Preſſurage, or with what has been preſs'd, which is taken from the Preſſings that they give to the Marc, becauſe the Caſks being always full, the Wine purifies itſelf the more, and becomes clear in leſs Time, and of Conſequence is more palatable, and may be ſold ſooner.

It is not enough to fill the Caſks up to the Bung the firſt time that the Wine is put into them; they ought to be fill'd many times; that is to ſay, as ſoon as the Boiling is over, Wine muſt be put in to excite it to boil; and the ſame Thing is to be done the next Day, and afterwards for eight or ten Days every other Day.

The Neceſſity there is of filling the Caſks as ſoon as the new Wine has been put into them, is proved by the Accident that happen'd to the Wines in the Year 1718, when the Seaſon was too hot and too dry during the Months of *July* and *Auguſt*.

The Wines were then ſo extreme hot as to boil very low in the Caſks, ſo that many, who had neglected to fill them at firſt up to the Bung, had their Wine turn'd ſour; which did not happen to thoſe who had uſed the Precaution of filling them to the Bung, and keeping them full: and for this Reaſon, thoſe who have many Tuns of Wine, ought always to take of the laſt they have made to fill all thoſe Puncheons of the other Tuns; and when a Perſon has but one, he muſt put of Wine in a Caſk call'd a *Gueulebée*, to fill thoſe Puncheons as far as to the Bung, as ſoon as the Wine has done boiling; then the Wine that remains muſt be put into the Caſks or *Gueulebée*, or into a very cloſe Veſſel, for fear of its evaporating or loſing its Spirit.

I will ſay, by the bye, that many deceive themſelves in making Wine theſe hot Years, for they let it ferment but a little, becauſe it boils as ſoon as it is trod; but this is but a falſe Boiling, which comes rather from the Fire that is in the Grape, than from the working in the Tun; therefore it ought to be tunned a conſiderable Time. It is in ſuch Years the Grapes ſhould the rather be ſtoned, and that the Wine ſhould be ſufficiently fermented.

It is true, there is ſome Inconvenience in filling the Caſks up to the Bung the firſt time the Wine is put in, becauſe it is impoſſible not to loſe ſome of it, for it will mix with the Scum and the Lee which comes out at the Bung; but this Inconvenience may be remedied, by ſetting Gutters above the Bung, and Pans or Veſſels of Wood under the Gutters, to receive all that which comes out.

And whereas ſome pretend that Lead communicates an ill Taſte to the Wine, it is the ſureſt way to have them of Tin, in ſuch manner, that nothing but the End of the Socket may enter into the Hole of the Bung; for if the Hole be made larger than that the Socket may play within it, the Gutter will be uſeleſs, becauſe the Wine would run out between the Wood and the Socket.

There muſt alſo be a Veſſel call'd *Gueulebée*, to empty theſe Veſſels in as they fill, and it ſhould be covered with a thick double Linen Cloth, and cloſed or faſtened all round about with a Hoop to hinder the Wine from growing flat.

The Lee deſcends by little and little to the Bottom of the Caſks, where it is joined with the Scum, which there falls together, and is incorporated with it.

Some Days after, the Wine being grown clear, they take away the Veſſel, and the Lee remains at the Bottom. This Wine may be put in a Veſſel by itſelf, without mingling with the Wine which is in the Caſks out of which it came. Some ſay this collected Wine is the more fine and ſtrong; but others ſay to the contrary: They may ſay what they will, but it is always true, that this Wine is very good, provided it has been kept very cloſe in the Veſſel where it was collected.

And I believe that one might, without any Scruple, make uſe of it for filling the Wine: But as to this, you need not conſult either the Merchants or the *Vignerons*; ſince the one have not Judgment or Sincerity enough, and the other are too much intereſted: And I ſpeak with a Knowledge of the Matter, founded on the Experience I have had many times, and without any Intereſt but that of the Publick.

Thoſe who from a covetous Temper will not be at the Charge of procuring theſe Gutters and Veſſels to receive the Wine of the Caſks while they are boiling, have no Skill in it; For the Wine which they would ſave by this means, would make amends intirely the firſt Year for the Expence they would be at in procuring them.

Others, that are afraid that they ſhall not ſell their Wine, ſay, that the Merchants have always an Opinion in favour of that Wine, of which the two Sides of the Bung of each Caſk are filled with Scum as far as the firſt Bands or Circles; and that they have a quite contrary Opinion of thoſe where it does not appear.

It is true, that formerly they did mind this, and their Opinion might be well grounded, becauſe they never made uſe of theſe Gutters: But at this Time their Opinion is alter'd; for they are perſuaded, that theſe Gutters being in uſe, a Caſk may have caſt out all the Scum without its appearing at the Sides of the Bung, becauſe it falls into theſe Veſſels that are ſet to receive it; and likewiſe, that all the Wine that is there is well mingled.

Beſides, it is an eaſy matter for a Merchant to know if there be much Lee in the Caſk, for he needs only to pierce it into the Lee, that is to ſay, at the Bottom, about two Fingers of the Notch of the Caſk where the Head-pieces come in.

The Wine having caſt out all its Scum, it will be proper to taſte all the Caſks into which it has been put, to the end, that if any one be found that has a bad Reliſh, to apprize thoſe of it who have furniſh'd them, that he may put all the bad ones to his own Account.

Some ſay, that St. *Martin's-day* being paſs'd you cannot oblige the Merchants, who have furniſh'd the Wine, to take that again which has been ſpoil'd in the Caſks, becauſe they ſay it is the more difficult to remedy it: Others pretend, that the Merchants are anſwerable three Months after the Caſks have been fill'd, provided they have not been remov'd from off the Stillings.

When the Wine has done boiling, it muſt be cover'd with the largeſt Side of the Bung, to hinder it from evaporating: And eight or ten Days afterwards it muſt be fill'd full, and bung'd up.

Some make uſe of Bungs about half a Foot long, becauſe they can take them away without daubing the Caſks with the Scum. But I am of the Opinion, that broad Bungs are better, and to make two Holes on the Side, the one about the Bigneſs of a little Foſſit, the other about the Bigneſs of ones little Finger, that a Tin Funnel may be put in, having in it a Piece of Tin ſoldered about two Inches from the End; the Holes of which may be as big again as thoſe of a Tobacco-Grater, to the End, that when one uſes it to fill the Caſks, neither Stone, nor Skin, nor Kernels, nor Lee, may paſs; The great Hole ſerves for the putting in of a Funnel, and the other to give Vent for the Caſks during the Time the Wine is pour'd in them.

This little Hole ought to be made at the Time that the Caſks are bored, to put in the Wine with the great wooden Funnel; for if the Socket does exactly fill the Bung-hole, the Caſk would fill but very ſlowly, if it had not Vent given it by the little Hole.

When it is done after this manner, the Tuns are not daub'd with the Scum; it is not diſturb'd, as is done in ſtriking to beat in the Bung, and the Wine will have leſs Vent.

You muſt be ſure to fill the Wine every fifteen Days after it has been bunged, until towards St. *Andrew*'s Day; you are not to meddle with it any longer till after the Severity of the *Winter* is over, which commonly happens towards the Middle of *February*, becauſe the Froſt may make it ſwell.

The *Auvernat* is not the only red Wine that we have in this Vineyard-plot; there are alſo other Wines made that have the ſame Colour, but are of a different Quality.

There is, for Example, the *Bon Lignage*, or the *Good Wine*, and that which is made of all Sorts of Grapes. As to the firſt, it is made up of the Red *Auvernat*, the Teint, the Grey, the White, the tender *Samoireau*, the *Melier*, and all the beſt Sorts of red Grapes.

The ſecond is compoſed of all Sorts of Grapes, good and bad, but more of the latter than the former; whence it is eaſy to be comprehended, why the one has leſs of the Quality than the other; and as this ſecond is generally ſpent in the Country, they make it all Manner of Ways, either fit for preſent drinking, or firm, or hard, according to the Occaſion they have for it, and the Quantity they are to provide. As to the other, they don't fail to make it, and often ſend it to *Paris*.

All theſe Sorts of Grapes are not gathered with the ſame Care as the red *Auvernat*, which cannot bear the Water, nevertheleſs the Wine is the better, when the Grapes with which it is made are cut in a Seaſon that is rather hot and dry than cold and moiſt.

We have in ſome Places of this Vineyard-plot, three Sorts of red Wines, which bear the ſame Name, which nevertheleſs they diſtinguiſh the one from the other; There is the tender *Samoireau*, the hard, and the *Fourchu*, which have all three different Qualities.

The tender *Samoireau* does very well in the Lands of the *Olivet*, *St. Meſmin*, and *Clery*, where it is more plentiful than any where elſe. They make of it a particular Wine, which will keep a long time, provided it have no Mixture, and that they give it but little of the Vat; this renders it firm, and prevents it from growing ropy.

This Grape may be mingled with the red *Auvernat*, becauſe they both ripen at the ſame time. The *Samoirean* gives the Colour to the *Auvernat*, it ſuſtains it, and cauſes it to keep a long Time; but you muſt put but a ſmall Quantity, for fear of altering, or entirely abſorbing the Quality of the *Auvernat*, which after it has loſt, it alſo loſes its Name, and is no more regarded, but as a good *Vin de Lignage*, or one compoſed of all Sorts of Grapes, which is vulgarly called *Vignerons Auvernat*, very different from that of the Citizens, which is in a Manner pure *Auvernat*. When one would render this *Vin de Lignage* yet better, he may put to it a fourth Part of good *Melier*.

The hard *Samoireau* is a little higher colour'd than the tender: when it has but its proper Degree of the Vat, they may mix one or two Puncheons of white, and a little leſs, when they tun it; they ſhould alſo, when it may be done, take a *Melier* of a better Kind, for this Wine has not much Fire. When it is pure, and it has paſſed the Year, that Quality diminiſheth; it is then proper to make uſe of Rapes, not of Chips or Shavings, but of Corn, without putting Grapes to it, as ſome do, for that renders it hard and diſagreeable to drink.

It is ſufficient to put a third Part, or at moſt a half of the Seeds into a Puncheon; and after that, they fill the Wine up to the Bung. They make uſe of theſe Rapes to put off the Grounds or Bottoms of Wine, and the weak Wines, which they alſo mingle ſometimes with them; the third Kind of *Samoireau*, of which I ſhall ſpeak, renders them the better for keeping.

The *Samoireau Fourchu* is the beſt of the three Kinds; this is proper to give the Colour to the others, and to ſuſtain thoſe that are weak, and to reſtore thoſe that have any Defect.

In order to know the Colour, they caſt ſome of it againſt a Wall; and according to the Impreſſion it makes, they judge of the Effect it will produce.

One ſingle Puncheon of that will colour ſix of white, and ſometimes more, according as the Seaſons are hot, and the Quantity of the Wine that the Vineyard has yielded: This Wine is not only good to drink, when it is taken in Time, but it ſerves for a Remedy againſt the Dyſentery and other Maladies. Its Marc is good againſt Rheumatiſms.

This Plant has a Virtue that is not found in any others, becauſe the longer it is kept the better it is: For it is better for drinking at the End of twelve or fourteen Years, than one or two Years after it has been made.

Some put it in Bottles, but it keeps equally as well in Caſks, provided Care be taken to keep them always full, and to obſerve that the Caſks don't want Hoops; and it will be proper to put on ſeveral Iron Hoops at each End.

The Wine, the Marc, and the Wood, or rather the Aſhes of this Plant, have alſo a great many other Properties, which I ſhall not relate.

The Time of gathering theſe two Species of *Samoireau*, comes much later than that of the firſt; that ripens at the ſame Time with the *Auvernat*.

The Territory of *Mardic* is the moſt proper for theſe Plants, and that which produces the moſt of it, (I mean of the hard and *fourchu Samoireau*) there is of it at *Bou* and *Checi*, and but a very little in any other Places of this Vineyard-plot.

As the *Fourchu* never produces more Wine than when it is a little old, many, eager to enjoy the Fruit of their Labours and their Expences, have not Patience to wait ſo long, and therefore they pull up thoſe of them they have, and can't reſolve to plant them when they have them not.

Nevertheleſs this is a precious Plant, and one may judge of it by the Effects that it produces, and by the Price which it bears, for it is commonly ſold for double the Price of the beſt Wines of this Country: And I don't know but that thoſe who deſtroy them, and thoſe that don't raiſe them, will repent it one time or other.

As there is not much to be ſaid of the Manner of making White-wine, and having taken Notice of it at the Beginning of this Article, I ſhall ſay but little of it particularly.

Altho' there are many Kinds of white Grapes, yet they make, as one may ſay, but two Sorts of Wine of them; the one is the moiſt, the other is dry Wine.

The firſt, ſuch as the *Muſcat*, or the *Gendin* of *St. Meſmin*, thoſe of *Marigny*, of *Rebrechein*, and other neighbouring Places, may be look'd upon as the moſt precious, in that they bring the Money into the Kingdom, rather than the dry Wines; for they ſend them into *Holland*, *Flanders*, *England*, &c. To render this Wine the better, they don't content themſelves to ſee that the Grapes have their perfect Maturity, and be half rotten; they wait oftentimes till the Froſt has taken them, to have the Wine which they call *Bouru*, and in ſome Years they defer the Vintage until the 15th or 20th of *November*, and it is then ſometimes ſo cold, that the Iſicles hang upon thoſe Grapes that periſhed, ſo that they are obliged to carry Fires into the Vineyards in great Pans, to warm the Gatherers.

It is true, that thoſe who tarry ſo long before they gather, have a great deal leſs Wine than others; but then at the ſame Time it is much better, and ſells a great deal dearer; ſo that I believe it comes much to the ſame, or very near the Matter.

The Wines of which I am ſpeaking, although ſweet of themſelves they have nevertheleſs not always the ſame Degree of Liquor; this depends upon the Condition of the Seaſon, that is to ſay, by how much the *Summer* and *Autumn* is the hotter, the Wine has the more Liquor, and it has a great deal leſs when the Seaſon is the contrary.

What I ſay is ſo true, that the Seaſon having been very hot in the Year 1719, the ſweet Wines themſelves had abundance more Liquor than ordinary, and kept good more than a Year; alſo the dry Wines of many Places were ſweet and clear.

Some red Wines were alſo very ſoft, (which is very rare) and held good till the Month of *February* in the Year 1721. It is true, they were thick, and that they did not become clear till the Time that they loſt their Sweetneſs, which alter'd their Strength.

The Softneſs of the white Wines being over, they were nevertheleſs good; but as there remains a certain Flavour, which pleaſes the Palate of moſt Perſons, it is beſt to ſell them, and ſpend them as ſoon as may be.

One may know by Experience, that good Grapes almoſt always make good Wine. Among the white Grapes, without Contradiction, the beſt are the *Melier* and the white *Auvernat* of the *Low Countries*; as the white *Formentes*, or *Bourguignons*, the *Maledeueaux*, the *Framboiſes*, the white *Gois*, &c. make a Wine, which is better to throw away than to drink; yet Vineyards of the *Vignerons* are ſtuffed with theſe wretched *Vines*, becauſe they yield more Wine, and for the moſt part better reſiſt thoſe Accidents that happen to a Vineyard; for theſe People have no Regard to any Thing but the Quantity, which is the Reaſon that they do not ordinarily ſell their Wines to that Advantage as the Citizens do.

The white Grapes cannot be gathered too ripe, becauſe the riper they are, the more Wine they produce, and their Rottenneſs does not give it any bad Taſte; but when it is begun before they come to their full Ripeneſs, they are ſubject to grow yellow; yet Regard is to be had to thoſe Lands of which the Wine is ſubject to grow ropy.

For this Reaſon, when they are gathered, it is good that the Grape has a little Greenneſs, to the end that the Wine that comes from them may be able to keep dry, to which the white *Auvernat* of the *Low Countries*, and the green *Melier* contribute very much; the laſt hinders the Wine from being ropy, and the firſt makes it clear; and for this Reaſon it is good to plant of it with the *Melier*, becauſe at the Time of gathering they may be both mingled together, and make a Wine without any Fault.

One ought to endeavour not to gather the white but when the Weather is fair, a rainy Seaſon is not ſo favourable; for one ought never to mingle Water with the Wine that one makes, though ſome are not over-ſcrupulous as to this Point; it is true, the Inconvenience is not ſo great in reſpect to the *Auvernats*; but that ſhould not hinder one from always endeavouring to make good Wine; and for this Reaſon it is beſt to gather the Vintage in a dry, hot Time.

As the white Wine is not tunned, when they bring the Grapes in Panniers from the Vineyards, they empty them directly on the Middle of the Preſs, where they trample them with their wooden Shoes; the broadeſt and ſmootheſt are the moſt proper for this Work.

The Grapes ought to be trod immediately, that is to ſay, every Pannier as they bring them from the Vineyard, otherwiſe the Wine would be yellow, and this Colour is diſagreeable to the Sight, and ſtill more to the Palate, and conſequently gives the Wine a bad Quality.

According as the Grapes are preſſed on the Middle, and that the Pipe fills, they empty it to fill the Puncheons or the Quarter Puncheons to a Pail full, or thereabouts, according to the Largeneſs of the Caſk wherein it is put; to make it boil, they fill them up to the Hole of the Bung with the Wine which comes from the two firſt Preſſings, and that which remained in the Pipe before they gave the two firſt Squeezings; and that which the others yield, ſerves to put into the Wine when the firſt Boiling begins to be diminiſhed.

One ought always to give to the Marc, whether it be white or red, four Preſſings, without taking in the Lowering of the Beam, that is to ſay, that it ought to be cut four Times.

Some give it the third Working, with an Iron Gripple in the Middle of the Marc, and they leave all round about half a Foot in Breadth, to keep in that which is wrought; and at the fourth Preſſing they cut the Border that they left, and put it back upon the other.

They pretend that a Marc ſo ordered yields the more Wine. As the Marc of white Wine is the more thick, and has leſs Fire than the *Auveraat*, it does not dry ſo preſently; for this Reaſon there ought to be longer Times between theſe Squeezings.

They give them theſe commonly in the Night-time, becauſe they do not lower the Beam, but when the Day's-work is finiſhed, when the Men who are to work the Marc have ſupped.

When the white Wine is cold, it muſt be filled up and bunged, and kept always full, at leaſt if it be not in the Depth of *Winter*; for when this Kind of Wine is emptied, it becomes yellow in moſt Countries; but when this happens, it is eaſily remedied, either by ſtirring it with a Stick of Hazel cleft into four, which is put in at the Bung-hole, or in ſhaking briſkly the Puncheon, which they leave ſometimes on the Bung, to the End that the Lee that deſcends thither, and afterwards is mixed again when the Caſk is turned up, will take away the Yellowneſs.

This ſecond Method ſeems to be the beſt; for beſides that the Wine does not take Wind, it is alſo done in a great deal leſs Time; for one is not obliged to unbung and bung again every Caſk; for they may be filled up with a ſmall Tin Funnel.

For ſome Years laſt paſt they have made Rapes of white Wines, from which they do not reap any great Advantage: They make uſe of them to mix with the coarſe, harſh red Wines, and that have but little of the Quality. In the mean Time, this fits the meaner Sort of People, who have not a very nice Taſte, in that it pleaſes their Palates, and is ſold cheap.

It will not be to any Purpoſe to name the Places of this Plot of Vineyards, which produce the beſt white Wines; for the Merchants don't take the Pains to make a Diſtinction between the Wines which have much of the Quality, from others that have leſs; beſides, they are many times deceived; for ſome Citizens, who have a great many Houſes of Wines in different Places, after the Vintage is over, they ſend that Wine they have made in one leſſer Vintage, to be added to that of another that is much better; and ſo a Merchant thinks that all the Wine he buys is from the ſame Place, when it is not.

I do not approve of this Practice of the Citizens; for a Merchant who would have Wine of one certain Place, will not be prepared to manage that which he ſhall have from another; becauſe thoſe different Wines will not produce the ſame Effects, with the Management he ſhall uſe to them; and no Perſon ought to be deceived.

When the Vintage, either of red Wines or white Wines, is finiſh'd, the Preſs ought to be taken Care of, that the Rats don't gnaw the Screw of it. It ſhould be rubbed with Garlick, the Smell of which thoſe Animals can't endure: It is alſo good to cover it with ſome old Caſks, to hinder any Filth from falling on the Screw, which can't be kept too clean.

Concerning Rapes, *or* New Wines.

Rapes have unhappily, for a conſiderable Time, been in uſe in theſe Vineyard-plots; and therefore I ſhall give ſome Account of them.

They make here three Sorts of Rapes in Vineyards.

The one is made of ſtoned Grapes: When they have put a Third or Half into a Puncheon, they tread them down, either before or after they have filled it with Wine. Some make it with Cuttings mingled with Grapes only, or with whole Grapes: But I do not approve of this Manner; for all the Wine which is put upon theſe Rapes always taſtes of the Grape-ſtone; and for this Reaſon it is better to take it away, and not to leave any Thing but the Grape, or at leaſt to take away the Stalk of the Grape.

The Troughs being opened, they lay upon the Bottom a Bed of Cuttings, and after that a Bed of Grapes, and this they do till the Troughs are almoſt full; but it muſt always be done in ſuch a Manner, that there muſt be a Layer of Cuttings upon each Bottom, or at each Head, to the End that the Wine may be the better drawn off, by the Means of a Tap, and after they have bored the Caſks, they fill them with Wine.

Thirdly, They make a Rape of Cuttings only, without any Mixture of Grapes.

The two firſt Sorts of Rapes are ſcarcely ſpent but in the Country, I mean, in this Vineyard-plot.

Nothing is more effectually uſeful in a Family, or that one may make uſe of for putting off Low-wines, or the Bottoms, and to give Colour and Strength to the Wines that want them, as I have ſaid in the preceding Article: but none but the beſt Grapes ought to be uſed for this Purpoſe, ſuch at the *Samoireau*, rather the *hard* or *fourchis* than the *tender*, the *Auvernat*, *teint* or *red*, a little of the *large black*, or of the *teint*; for if theſe two laſt have not Strength, they have much leſs of the Colour, and render the Wine marrowy or ſubſtantial.

Theſe Rapes muſt be well boiled, and three or four Months after this has been done, that is to ſay, after the *Winter*, they muſt be cleared or purified: Forty or fifty Pints may be drawn out of a Puncheon, and be put immediately into Wine that has leſs Colour, but is very near of the ſame Strength; for the Rape ought not to be too ſoon weakened, nor the Wine too often mixed with it.

The Wine being once upon the Stillings, ought not to be removed: This is the Reaſon why the Caſks in which it is to be put, be of Wood that is well choſen and barred, having a double Hair-cloth at each End.

This Precaution muſt be uſed at the Time when they are ſold, or before they are removed from the Place where they are made, or in putting them into Vaults: For theſe Rapes of Cuttings are made rather to be conſumed in other Countries than in our own.

They make uſe of this at *Paris*, and other Places, to put off the bad ſmall Wines, which would never ſell but for theſe Rapes; for without this, I know not what the *Pariſians* would do with their wretched, ſmall, tart Wine, which their Vineyards of the *French* Country produces them.

This Wine is ſo pitiful, eſpecially in rainy, cold, moiſt Years, that it is not able to ſuſtain itſelf, and is ſpoiled before it is vended.

The Cold takes from it that little Quality that it has, and the Heat turns it; ſo that every Thing is contrary to it; and one may ſay, the beſt of theſe Wines are ſuch as have neither good or bad Quality.

Therefore one would chuſe to pull up the greateſt Part of the Vineyards that are about *Paris*, becauſe they produce ſuch poor Wine, that to make them paſs, there is an abſolute Neceſſity to have Recourſe to theſe Rapes.

Of Vineyards in England.

There have of late Years been but very few Vineyards in *England*, tho' they were formerly very common, as may be gather'd from the ſeveral Places in divers Parts of *England*, which yet retain that Name; as alſo from ancient Records, which teſtify the Quantities of Ground which were allotted for Vineyards, to Abbeys and Monaſteries, for Wine for the Uſe of the Inhabitants: but as to the Quality of the Wines which were then produced in *England*, we are at preſent ignorant; and how theſe Vineyards were rooted up, and became ſo generally neglected, we have no very good Accounts left. Whatever might be the Cauſe of this total Neglect in cultivating *Vines* in *England*, I won't pretend to determine; but ſuch was the Prejudice moſt People conceived to any Attempts of producing Wine in *England*, that, for ſome Ages paſt, every Trial of that kind has been ridiculed by the Generality of People; and at this Day very few Perſons will believe it poſſible to be effected.
